CHICAGO, Jan. 30—Four hundred representatives of the various automotive industries outlined their activities for the reconstruction period in connection with the home-coming supper and afternoon technical session of the Society of Automotive Engineers at the Hotel Morrison to-day. While most engineers realize the pace throughout the automotive world will be much faster in the coming years, there is a feeling of optimism that whatever conditions prevail the engineers of the country will shape the destinies of their respective industries in the same satisfactory manner as was done throughout the war period. President Kettering stated that as a result of war work we have on hand a tremendous amount of technical information, all or some of which will undoubtedly be used by engineers and designers in the motor car, truck, tractor and airplane field.

Besides President Kettering, the speakers of the evening included George W. Smith, assistant chief engineer Nash Motors Co. and chairman of the Midwest Section, S. A. E.; H. H. Merrick, president Chicago Association of Commerce; Col. Chauncey Baker, Quartermaster Department, Motor Transport Section; William B. Stout, United Aircraft Engineering Corps, New York. E. E. Peake, executive secretary National Automobile Dealers' Association, acted as toastmaster. The afternoon session was given entirely to reading and discussion of technical papers, the severity of which, however, was relieved by Capt. Mark Smith, U. S. M. C., who told of his experiences at Chateau-Thierry.

Stewart-Warner Earns $1,504,664

CHICAGO, Feb. 5—The Stewart-Warner Speedometer Corp. showed net profits for the year ending Dec. 31, 1918, of $1,594,664 after Federal income, excess profits and war profits taxes were deducted. As compared with $1,860,774 for 1917, this is a loss of $365,110. After dividends were paid, a surplus of $994,664 remained, as compared with $1,260,774 for 1917. Net profits for 1918 are equal to 15.94 per cent on capital stock, which was recently raised from a 6 to an 8 per cent per annum basis.

The comparative statement for 1918 and 1917 follows:

	1918	1917
Profit and income, after deducting expenses, depreciation, etc.	$2,002,646	$2,234,824
Provision for taxes	407,982	374,050
Net profit	$1,594,664	$1,860,774
Dividends	600,000	600,000
Surplus	994,664	$1,260,774
Previous Surplus	5,456,216	4,195,442
Total Surplus	$6,450,880	$5,456,216

Indict 13 Pan-Officers

CHICAGO, Feb. 1—Indictments against thirteen officers and directors of the Pan Motor Co., St. Cloud, were returned today by the Federal Court, charging the use of mails to defraud. The indictment alleges a stock-promoting scheme.

The concern is incorporated under the laws of Delaware and the men indicted are: Samuel C. Pandolfo, St. Cloud, president; Norman A. Street, promoter, Chicago; George Heitman, Chicago; H. S. Wigle, Spokane, Wash.; John Barritt, St. Cloud; Charles D. Schwab, St. Cloud; Fred Shilpin, St. Cloud; Charles Bunnell, St. Cloud; George E. Hanson, St. Cloud; Charles F. Ladner, St. Cloud; Peter R. Thielman, St. Cloud; Hugh Evans, St. Cloud, and H. C. Erwing, Jr., St. Cloud.

The indictment charges that approximately $5,500,000, including $250,000 in Liberty Bonds, was accepted from 50,000 working people throughout the country.

A recent financial statement issued by the company, the indictment asserts, claims that the company had a surplus of $2,500,000, although it never was on a production basis. The surplus, it is charged, was created by capitalizing intangible assets.

National Show Managers' Association Re-elects Officers

CHICAGO, Feb. 4—At the annual meeting of the National Association of Automobile Show Managers last week all the officers of the organization were reelected, as follows: President, E. E. Peake, Kansas City; vice-president, Bart J. Ruddle, Milwaukee; secretary-treasurer, Ray W. Sherman, Motor World, New York.

No Automobiles for Sale by Army

WASHINGTON, Feb. 4—Further official denial of the rumors that the army is selling passenger automobiles was made here to-day by the War Department. A public statement given to the press denies that dealers or others have purchased any cars from the army, and adds that second-hand dealers who advertise that they have cars for sale purchased from the government are not telling the truth. Following is the announcement:

"There are persistent rumors all over the country to the effect that the War Department is disposing of a large number of automobiles by auction or private sale at reduced prices and in many cases to brokers. At the present time there are available no passenger automobiles for sale. New cars will be turned back through the original manufacturer in every case where practicable.

"It has been noted that a number of second-hand dealers have advertised from time to time quantities of new or nearly new material which they claim to have purchased from the War Department. These cases have been investigated, and in every instance so far, material advertised has not been property of the dealer and the Government had no intention of selling him this property. In this connection it should be distinctly understood that it is not the policy of the War Department to sell property to anyone for speculative purposes."

Jordan Prices Drop

CLEVELAND, Feb. 3—The Jordan Motor Car Co. has reduced the price of five of the company's six models as follows:

Model	New Price	Old Price
Touring car	$2,475	$2,775
Four-passenger sport model	2,475	2,775
Sedan	3,500	3,750
Four-passenger brougham	3,500	3,750
Town car	3,500	3,750
Limousine	3,750	3,750

Rickenbacker, American Ace, Honored at Banquet

NEW YORK CITY, Feb. 4—Captain E. V. Rickenbacker, America's ace of aces, shared plaudits with his mother last night when the nation officially welcomed the former racing driver at a banquet given in his honor by the Contest Board of the American Automobile Association and allied motoring and aviation organizations at the Waldorf-Astoria. Seven hundred of the big men in motoring and aviation gathered to do honor to the man who had brought down twenty-six Huns. Secretary of War Baker, Chief, Bureau Aircraft Production. Major-General Menoher, Congressman Ireland, ex-Congressman Bourke Cochrane and others voiced the welcome of the victorious flyer's admirers. Cablegrams were read from General Pershing and others who had known Rick in service and on the speedways. Through Rick his friends presented his mother with a pair of platinum wings set with diamonds and sapphires in honor of her eagle son.

Studebaker Branch Management Changes

NEW YORK, Feb. 3—F. R. Bump, who has been manager of the Studebaker branch for many years, has resigned, and Ira C. Jones has taken up his duties. Mr. Jones was formerly the owner and proprietor of a wholesale jewelry business in New York. He has brought F. L. Sholes into the organization to be retail manager, and F. W. Beinecke, who will be in charge of service. Mr. Sholes was formerly the factory sales manager of the specialty department of the American Can Co. and Mr. Beinecke was in charge of the rolling stock of the Texas company.

More Ford Tractor Plants

DETROIT, Feb. 3—The Ford Motor Car Co. is planning a period of expansion. The completion of the $7,000,000 tractor factory here is followed by the statement of Mr. Ford that he is preparing to build a tractor factory on the Hudson River, another in Ontario and another plant will be built and transported bodily to Mexico.

Bethlehem Motors Building Tractors

ALLENTOWN, PA., Feb. 3—The Bethlehem Motors Co. is now building a tractor in addition to its line of trucks. It is hoped to have an exhibition model ready in time to be at the Kansas City Tractor Show.

New Overland Price Is "Mystery"

DETROIT, Feb. 3—The price of the new light Overland four to be placed on the market May 1 by the Willys-Overland Co., Toledo, has become one of the main topics of discussion in automotive circles. Since the chassis was introduced at the January show last year the trade has been waiting for the new machine and a price announcement. From the Toledo factory comes word that the price will not be made public until the cars are in the hands of the distributers.

Rick's Record Is 100% Perfect

No Damaged Planes Despite 26 Victories—69 Planes to Credit of Squadron 94

NEW YORK, Feb. 1—Eddie Rickenbacker, former racing star, returned on the Adriatic as Captain Rickenbacker, American ace, with 26 Hun planes to his credit in the short period of 7 months that he was on the American front in France. He comes home with more planes than any other aviator in the American service, his closest rival being the late Raoul Lufberry, shot down in France some months ago, who had 18 to his credit. Captain Rickenbacker left his squadron, the Ninety-fourth, of which he was commander, the day after Christmas, and is proceeding to Washington on military orders. His was the leading American squadron, with 69 Hun planes as its share. It is not known whether he will remain permanently in this country or not.

His squadron, whose work began at Chateau-Thierry in July and continued until the armistice Nov. 11, was selected to accompany the army of occupation to Coblenz, a coveted honor for any squadron.

Captain Rickenbacker, or Eddie or Rick, as we still prefer to call him, had a truly meteoric career in the war. He was ordered to the front as an aviator on April 14, 1918, and got his first Hun on April 29. It was from that date up to November that he won the highest honor that could come to an American aviator. He chalked up more victories than any of our flyers in the Lafayette squadron, which had over three years' experience in France. He proved himself as fearless a fighter against the Boche as he was a racing driver on our speedways. In flying, however, he was more fortunate. He had machines, a Nieuport and a Spad, that he could not break up. In his old racing days on Indianapolis and other speedways he ran the wheels off his cars, burned out bearings and put himself out of the winning. In aviation his record has been 100 per cent perfect. He has never crashed a single machine. In training he never once broke up a plane, nor even a wing or a tail.

He brought down 18 Boche planes on his Spad fighter and never crashed or broke his machine. He never had to have a new rudder or elevator put on. Even the 220-hp. Hispano-Suiza engine lasted him for 120 hours, although the average life of these engines in fighting service was 9 hours.

Once Rick was caught in a dog fight. That is what the show was called when eight or ten Boches attacked three or four Allied planes. Rick had been out nearly the limit of the two hours and fifteen minutes for which his Nieuport carried gasoline supply when the dog fight started. He finished the scrap, getting one Hun, and then made for across the front line trenches and home. Before he reached the lines his engine oil was exhausted, the bearings seized, and he was just able to glide across No Man's Land and make a forced landing between rows of barbed wire in an open field. But his pilotship was so expert that even here he did not crash his machine. He tore the tail skid off, but did not crush the landing gear. It was necessary to take the wings off before the plane could be removed to the squadron.

Rick is accompanied by two aces from his squadron. One is Major Meissner of Brooklyn, with 8 victories to his credit, and the other is Capt. Douglas Campbell of Mount Hamilton, Col., who brought down 7 Boches. Both are reporting to aviation headquarters at Washington with Captain Rickenbacker.

Rick left him famous Ninety-fourth at Coblenz in charge of Reed Chambers, who, before going to the war, was the Cadillac agent at Memphis. He is now Captain Chambers, with 7 victories on the official record.

Some of Rick's other fighting "94's" had previous connections with the motor industry, and some were boys fresh from college. Samuel Kayes, with four Boche victims, was the Ford agent at Columbus, Miss. He is still with the squadron at Coblenz.

Wierd Cook, Anderson, Ind., was one of the college graduates, a mere lad from school. Yet he had 6 victories when Nov. 11 ended the show.

Joe Dawson, Denver, Col., no relation to the old race driver, was another fighting member of the 94th, and got 6 Boches.

The squadron, although officially made up of twenty-five planes, was in service with twenty-four and about twenty pilots. They all flew Spads, type XIII, fitted with Hispano-Suiza engines. The Spad is France's best single-seater scout fighter, and has a flying speed of 135 m.p.h., with a driving speed as high as 300 m.p.h. All American fighting scouts used the Spad the last few months. Previous to that many of them used Nieuport Scouts, also French machines, with a rotary air-cooled engine. These were not so recent a creation as the Spad.

—

NEW YORK, Feb. 3—Captain Eddie Rickenbacker, America's Ace of Aces, and former racing driver, if he does not change his mind, is out of motor racing for good. While his future is quite unsettled, and he is only home on official orders to report to headquarters in Washington, he has a strong desire to spend the remainder of his days in aircraft service. Indications that his service to his country will not be concluded with his return to America are apparent in the announcement by Director of Publicity Wilson of the Liberty Loan Bureau of the Treasury Department, that for the next month Rickenbacker will pilot a plane doing stunts in Ohio cities to promote the Fifth Liberty Loan.

His ambitions are not to remain a pilot, but may follow either of two directions: First, to continue with the army or Government in aircraft work, or, second, to go into the commercial end, either in engineering or other work.

Michigan and Ohio Car Production

63,246 Passenger Cars Built in January, With Factories Running Below Normal

DETROIT, Jan. 31—Production figures given out by the leading automobile companies of Michigan and Ohio show that approximately 63,246 passenger cars were made during January, notwithstanding the fact that a majority of the concerns were running below normal production and some were not in production at all. The figures are fairly accurate and show that the delay attendant on reconstruction work will very likely curtail the 1919 car output 33 1/3 per cent.

Had normal conditions prevailed, the number of cars made in this district in 1919 would have exceeded the 3,000,000 mark, and may even have a total of 3,500,000, automobile manufacturers contend. Delay in contract settlement and in shifting the big plants from a war to a peacetime basis will cut the estimated production to approximately 2,000,000 machines, unless the trade demands necessitate the adoption of an over-time schedule by the larger plants.

Thirty-two manufacturers submitted production figures. Oldsmobile and Chevrolet figures were not available. The Packard, White, Jackson and King companies are not in production. The King people will start making cars this month. The White and Jackson companies may both produce a passenger car this year.

Ford production is now 1300 cars a day, which is more than half below normal. This company will be hitting the 3000 mark by the middle of March. The production tabulation follows:

Car	Daily Production
Buick	100
Briscoe	30
Cadillac	55
Chalmers	30
Chevrolet	
Columbia	8
Dodge	300
Dort	40
Ford	1300

Continental Motors Has Surplus of $555,030 Over 1917

DETROIT, Feb. 1—A comparison of the financial statements of the Continental Motors Corp. for 1917 and 1918 shows that the company's surplus for 1918, in spite of war conditions, is $555,030 over 1917. The company has completed its war contracts and has closed down for ten days to take inventory. It is now running at 80 per cent capacity, amounting to 180,000 cars a year, with 5000 men employed.

The following is the comparative financial statement of the two years:

CONTINENTAL MOTORS STATEMENT

Assets	1918	1917
Property account	$7,395,722	$7,201,808
Investments at cost	31,756	6,756
Deposit with trustee for retir'm't of pfd. stock	1,243	——
Inventories	6,022,357	5,068,956
Accounts and notes receivable—less reserve	1,840 596	1,428,092
Liberty Loan bonds	210,996	——
Thrift stamps	1,229	——
Cash in banks and on hand	172,818	369,421
Deferred charges to future operations	48,552	42,879
	$15,725,270	$14,117,912
Liabilities		
Capital stock	$10,448,070	$10,720,070
Notes payable	850,000	1,025,000
Accounts payable	1,828,945	855,179
Accrued payrolls, taxes, int., etc.	1,042,645	517,083
Surplus	1,555,610	1,000 580
	$15,725,270	$14,117,912

After deducting canceled army contracts, the company's books Oct. 31 last showed orders amounting to $19,781,000. In the fiscal year 494 stockholders were added, making the total 3961.

The profits for the year were $3,045,545. After deducting the amount reserved for federal excess profits and income taxes, $515,000; depreciation provisions, $524,508, and the interest on borrowed money amounting to $66,253, there remained a balance or net profit for the year of $1,939,785.

The company's financial statement shows $75,000 was added to land investment, principally by purchase of 33 acres adjoining its Muskegon plant, giving that plant 50 acres. Inventory was increased about $950,000, much of which represents material bought for government work. In the fiscal year dividends amounting to $238,281 were paid on preferred stock and $1,401,066 on common. Allowing for dividends and reserves, a balance of $1,555,610 remained in surplus, an increase of more than $500,000 over 1917.

The income statement shows a balance of $1,939,785 for net profits after allowing $1,105,760 for interest and depreciation charges, reserves and federal income and excess profit taxes, federal taxes being estimated at $515,000.

Richardson Heads Studebaker Foreign Sales

NEW YORK, Feb. 5—D. B. Richardson, who was manager for the Studebaker Corp. in South America, with headquarters in Buenos Aires, has taken charge of Studebaker foreign sales. His headquarters will be in South Bend.

Moline Plow Co. Makes Report Covering 15 Months

MOLINE, ILL., Jan. 31—Net profits equivalent to 9.14 per cent per annum on the common stock are disclosed in the report of the Moline Plow Co. for the 15 months ending Oct. 31. This is arrived at after providing for dividends on the first and second preferred stocks and after charging all operating expenses, including depreciation allowance and interest on borrowed money. The profit and loss surplus as of Oct. 31, 1918, stands at $2,717,512.

ASSETS

	1918 (15 months)	1917 (12 months)

Bill to Validate Contracts Is Passed

(*Continued from page* 331)

AN ACT

To provide relief where formal contracts have not been made in the manner required by law.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That whenever during the war emergency and prior to Nov. 12, 1918, any individual, firm, company, corporation, or foreign Government has made an agreement with the Secretary of War, or with any officer or agent acting under his authority, or with any agency of the Government authorized to procure for the War Department, for the production, manufacture, sale, acquisition or control of equipment, materials or supplies, or for services, or for facilities, or other purposes connected with the prosecution of the war, and such agreement was reduced to the form of a contract or accepted procurement order and executed or signed on behalf of the Government, but the agreement did not comply with statutory requirements, in every such case the Secretary of War is authorized and directed to waive, on behalf of the Government, such noncompliance: Provided, That he finds such waiver is not inconsistent with the public interest, and in this event the said agreement shall have the same validity and effect it would have had if such statutory requirement had been complied with: And provided further, That such waiver shall not validate such contract or procurement order in so far as any claim for unearned profits may be involved.

That whenever, prior to said Nov. 12, 1918, any individual, firm, company, corporation, or foreign Government has made any agreement, oral or written, express or implied, with, or has received any order or request, oral or written, from the Secretary of War, or any officer, agent, or agency as aforesaid, for any of the purposes aforesaid, and the same has not been reduced to contract form, or when the Secretary of War has not waived such noncompliance, but such individual, firm, company, corporation, or foreign Government has in good faith made expenditures, incurred obligations, acquired or furnished facilities, equipment, materials, or supplies, or rendered services, in reliance on such agreement, order, or request, in every such case the Secretary of War is authorized and directed, on behalf of the Government, to enter into such contract with such individual, firm, company, corporation, or foreign Government as will, under all the circumstances, fairly and equitably compensate him or it for the expenditures made, obligations incurred, equipment, materials, or supplies furnished or acquired, or services rendered, as aforesaid: Provided, That in no event shall such contract provide for compensation on terms more favorable than the terms, if any, for which the aforesaid agreement, order, or request may have provided.

That whenever, prior to said November twelfth, nineteen hundred and eighteen, the War Department, through its officers or agents, has taken possession of any land, or whenever the holder or owner of any land has removed from or removed any improvements from such land at the order or request of the War Department and no valid contract has been made with respect thereto, then the Secretary of War, if he finds that the public interest does not require the possession or occupancy of such land by the Government, is authorized to make compensation to the owner or holder thereof for the fair value of such improvements so removed and the expense incurred by such owner in removing therefrom or for the fair value of the use of such land of which the War Department has taken actual possession and for any expense or loss incurred by the owner or holder by reason of such possession.

Sec. 2. That a commission is hereby created and established, to be known as the War Contracts Appeals Commission (hereinafter referred to as the commission), which shall be composed of three members, who shall be appointed by the President, by and with the advice and consent of the Senate, and shall continue in office for one year from the date of this Act. One member of the commission shall represent the War Department, one member shall represent the Department of Justice, and one member shall represent the business interests of the country. None of the members of the commission shall be interested in any order, contract, or agreement within the purview of this Act or have any interest in any firm or corporation having such orders, contracts, or agreements. Each member of the commission shall receive a salary of $7500 a year, payable in the same manner as the salaries of judges of the courts of the United States. The commission shall choose a chairman from its own membership and may appoint a secretary, who shall receive a salary not exceeding $5000 a year, to be determined by the commission and payable in the same manner as the salaries of the members of the commission.

That there is hereby appropriated, for the purpose of defraying the reasonable expenses of the commission, including the payment of salaries herein authorized, out of any money in the Treasury of the United States not otherwise appropriated, available immediately and until expended, the sum of $50,000.

That within thirty days of the date when the Secretary of War offers any contract or compensation as provided in this Act or refuses to offer such contract or compensation, the party to whom said contract or compensation is tendered or refused, or the Government by a duly authorized officer from the Department of Justice may file with the chairman of the commission a notice of appeal: Provided, however, That if the representative of the Department of Justice agrees with the action of the War Department there shall be no appeal by the Government, but settlement can be made at once. If the Secretary of War shall refuse to waive noncompliance with statutory requirements in respect to any agreement within the purview of the first paragraph of section one of this Act or upon the expiration of sixty days from the date of the taking effect of this Act shall have failed to waive such noncompliance, the contractor named in any such agreement may, within thirty days after such refusal or after the expiration of such sixty days file with the chairman of said commission a notice of appeal. In all cases where an appeal is taken hereunder the commission shall proceed to examine and review the facts and circumstances

of the case and make its award or finding thereon according to the justice and equity thereof. Upon giving receipt in full of all demands against the United States arising out of the transaction by reason of which the award is made, the appellant shall be entitled to receive the amount of any award so made, and the proper officer of the United States is hereby authorized and directed to pay the same, but if the appellant is dissatisfied with the amount so awarded he shall be paid seventy-five per centum of the amount awarded and shall be entitled to sue the United States in the Court of Claims to recover such further sum as added to said seventy-five per centum shall make up such amount as will be fair and just compensation as provied in this Act, and the Court of Claims is hereby given jurisdiction to hear said suit and render judgment therein.

That whenever the Secretary of War and the contractor shall fail to agree in the matter of the adjustment or settlement, or as to the interpretation or application of the terms, of any contract which has been made for any of the purposes set forth in this Act, and in the execution of which there has been compliance with statutory requirements, or compliance has been waived as herein provided, the contractor or the Government by a duly authorized officer from the Department of Justice may give notice to the Secretary of War of intention to appeal to the commission, and provided notice of appeal is filed with the chairman of the commission within thirty days: Provided, however, That if the representative of the Department of Justice agrees with the action of the War Department there shall be no appeal by the Government but settlement can be made at once. On an appeal being taken the commission shall thereupon proceed to determine the questions at issue as set forth in said notice of appeal; and the contractor shall be entitled either to receive the whole amount of such award as may be made as in full of his claim on the questions submitted or seventy-five per centum of the same and sue the United States in the Court of Claims for any remainder, all as provided next above as to agreements otherwise within the purview of this Act.

That in executing the duties and powers conferred by this Act the commission may make its own rules and regulations and may hear and determine issues informally. It shall be the duty of the Secretary of War to furnish to the commission such evidence, documents, or papers pertaining to transactions as to which notice of appeal has been filed as the commission may request. The commission is authorized in its discretion to appoint an examiner in any region or district when such region is within the United States where in its judgment the taking of additional testimony is necessary to the determination of any case. Such examiner shall be a resident of the region or district for which he is appointed, and shall not have any interest, directly or indirectly, in any contract or transaction coming before him or receive any compensation save and except such per diem compensation and expenses as shall be fixed by the commission. Whenever the commission shall refer to any such examiner any claim presented hereunder, the examiner shall proceed, under the direction of the commission, to hear the parties, take the proofs, and return the same to the commission with his recommendations thereon as promptly as possible: Provided, That in no case shall any award either by the Secretary of War, the commission, or the Court of Claims include prospective or possible profits on any part of the contract beyond the goods and supplies delivered to and accepted by the United States and a remuneration, which may include a reasonable profit, for expenditures and obligations or liabilities necessarily incurred in performing or preparing to perform said contract or order; Provided further, That the foregoing proviso shall not apply to any contract executed in compliance with all statutory requirements.

Sec. 3. That nothing in this Act contained shall be held to validate any such contract unless the officer who was at the time of the making of such contract the chief of the division or bureau, as the case may be, in which said contract was negotiated, or in the event that such officer was not responsible for the making of such contract, then the officer in such division or bureau who was so responsible, together with the officer who signed said contract, shall each severally make and subscribe to an affidavit in writing, giving the definite terms of such contract, the name or names within his knowledge, of any such officer or officers who took part in the negotiation or making of the same, and stating whether or not within his knowledge any officer aiding in such making was interested, directly or indirectly, in said contract, and in addition subscribing to an oath to be appended to said affidavit in substantially the following form and tenor:

"I, ————, Chief of the Division or Bureau (naming it) in which the contract hereinbefore mentioned was negotiated, at the time of negotiation thereof, and the officer in the Division or Bureau (naming it) responsible for the making of the contract hereinbefore mentioned, and I, ————, the officer who actually signed said contract, do hereby each severally swear that I am not and was not at the time of the making of said contract directly or indirectly interested in said contract."

That in respect to any such contract as to which any one of said officers can not take the foregoing oath, or after diligent search or inquiry by the contractor can not be found, or is at the time actually engaged in foreign service, or refuses to take said oath, then upon such facts and the fact required in the oath of such officer, appearing by an affidavit of the contractor, or of one of its partners, chief officers, or chief agents acting in its behalf, the Secretary of War shall promptly report such contract to the War Contracts Appeals Commission, and furnish to said commission such evidence, documents, and papers pertaining to the transaction as may be within his control, and such commission may request, and original jurisdiction is hereby vested in, said commission to hear and determine said claim with the powers and upon the procedure hereinbefore described in this Act. Said commission shall make its award or finding thereon, and deny said claim or grant it in whole or in part, according to the justice and equity thereof, and the award or finding shall have the same force and effect, and create the same rights as if made under the provisions of section three of this Act. And it shall be the further duty of said commission in hearing, investigating, and determining such claim to find and determine whether any of such officers is or was at the time of the making of said contract directly or indirectly interested in said contract.

Sec. 4. That nothing in this Act contained shall be construed to validate any agreement, contract, or order procured by fraud or to relieve any officer or agent of the Government from prosecution under the penal statutes of the United States for any fraud, criminal conduct, illegality, or irregularity in connection with any of the agreements or orders referred to herein or the execution or signing thereof. In all proceedings hereunder witnesses may be compelled to attend, appear, and testify, and produce books, papers and letters, or other documents; and the claim that any such testimony or evidence may tend to criminate the person giving the same shall not excuse such witness from testifying, but such evidence or testimony shall not be used against such person in the trial of any criminal proceeding.

Sec. 5. That no settlement of any claim arising under the provisions of this Act shall bar the United States Government through any of its duly authorized agencies, or any committee of Congress hereafter duly appointed, from the right of review of such settlement, nor the right of recovery of any money paid by the Government to any party under any settlement entered into, or payment made under the provisions of this Act, if the Government has been defrauded, and the right of recovery in all such cases shall extend to the executors, administrators, heirs, and assigns, or any party or parties: And provided further, That nothing in this Act shall be construed to relieve any officer or agent of the United States from criminal prosecution under the provisions of any statutes of the United States for any fraud or criminal conduct: And provided further, That this Act shall in no way relieve or excuse any officer or his agent from such criminal prosecution because of any irregularity or illegality in the manner of the execution of such agreement: and Provided further, That the names of such contractors and the amounts of such partial or final settlements shall be filed with the Clerk of the House for the information of Congress and printed in the Congressional Record, or as a public document, within ten days after such confirmation.

Sec. 6. That whenever, under the provisions of this Act, the Secretary of War shall make an award to any prime contractor who shall have sublet any part of said contract for material, equipment, or supplies to any other person, firm, or corporation who has in good faith made expenditures, incurred obligations, rendered service, or furnished material, equipment, or supplies to any prime contractor, with the knowledge and approval of any agent of the Secretary of War duly authorized thereunto, the Secretary of War shall apportion the amount of said award justly due to each of the subcontractors of said prime contractors. Before payment of said award the Secretary of War shall require any prime contractor to present satisfactory evidence of having paid said subcontractors or of the consent of said subcontractors to look for their compensation to said prime contractor only; and in the case of the failure of said prime contractor to present such evidence or such consent, the Secretary of War shall pay directly to said subcontractors the amount found to be due under said award; and in case of the insolvency of any prime contractor the subcontractor of said prime contractor shall have a lien upon the funds arising from said award prior and superior to the lien of any general creditors of said prime contractor.

Sec. 7. That the Secretary of the Interior be, and hereby is, authorized and directed to ascertain and determine the amount or amounts of money heretofore invested or contracted to be invested and obligations incurred by any and all persons and investors for producing or for the purpose of producing or preparing for producing, within the United States, to supply the urgent, published, and evident needs of the Nation during the war, any ores, metals, minerals, or mineral substances mentioned and enumerated in an Act of Congress approved October fifth, nineteen hundred and eighteen (public, numbered two hundred and twenty), entitled "An Act to provide further for the national security and defense by encouraging the production, conserving the supply, and controlling the distribution of those ores, metals, and minerals which have formerly been largely imported, or of which there is or may be an inadequate supply"; the production of which by any claimant or claimants was requested, or demanded, by personal solicitation of, or personal inducement to, such claimant or claimants made by the War Industries Board, the Shipping Board, or the Department of the Interior.

And that said Secretary ascertain, determine, adjust, liquidate, and out of the moneys provided and appropriated by said Act pay to the parties entitled thereto the amount of such loss and damages as he, the said Secretary, shall find and determine have been sustained and suffered or are likely to be sustained and suffered, by reason of having made such investments for said purposes or having produced surplus stocks of such materials; and that in each case he shall make such determination, provision, settlement, advancement, or final payment, and by agreement with owners and claimants make such other adjustment, or take such other action as he shall find and determine to be just, equitable, reasonable, and expedient; and that he make such provisions as he may deem necessary, advisable, and reasonable to prevent further losses pending final decision, settlement, and disposition in any case or cases; that the payments herein authorized be made to the claimant or claimants the said Secretary shall find to be morally, equitably, and justly entitled thereto; that in ascertaining and determining the losses and damages sustained or to be sustained, and the adjustments, settlements, payments, and provisions to be made, the said Secretary shall consider the prices and conditions existing at the time of each investment and the prices and conditions existing prior to the war, as well as those existing at the time of such determination, adjustment, and settlement, together with all of the circumstances and conditions of each case; that the final determination, decision, provision, disposition, and action of said Secretary in each case shall be conclusive and final; that all payments shall be made and all expenses incurred by the Secretary paid from the funds and appropriations provided and appropriated by said Act of October fifth, nineteen hundred and eighteen (public, numbered two hundred and twenty), and that said funds and appropriations shall continue to be available for said purposes until such time as the said Secretary shall have fully exercised the authority hereby granted and performed and completed the duties hereby provided and imposed: Provided, however, That said Secretary shall consider, approve, and dispose of only such claims as shall be made hereunder and filed with the Department of the Interior within three months from and after the approval of this Act.

That a report of all operations under this section, including receipts and disbursements, shall be made to Congress on or before the first Monday in December of each year.

That nothing in this section shall be construed to confer jurisdiction upon any court to entertain a suit against the United States.

Amend the title so as to read: "An Act to provide relief in cases of contracts connected with the prosecution of the war, and for other purposes."

Passed the House of Representatives January 9, 1919.

Attest: SOUTH TRIMBLE,
Clerk.

Passed the Senate with amendments January 28 (calendar day, January 30), 1919.

Attest: JAMES M. BAKER,
Secretary.

WASHINGTON, Feb. 1—The following contracts were placed by the Motors Division, Quartermaster Department:

Dodge Bros., Detroit, motor equipment. Set of equipment to accompany each order motors A-45 and motors A-46, at $75.17 each.
Dodge Bros., Detroit, crating and box. Box and crate for export at $53 each, as per P. S. and T. Bulletin No. 22.
Dodge Bros., Detroit, substitute equipment. Substitute for 500 sets of equipment for Dodge delivery wagons, as per attached list.
Dodge Bros., Detroit, price determined. Price on 1000 sets extra equipment in original contract now determined at $75.17 per set.
Ford Motor Co., Detroit. War tax changed to $14.07 instead of $14.51 as originally specified.

—

WASHINGTON, Feb. 1—Following is a list of contracts made by the Bureau of Aircraft Production:

Dayton Engineering Laboratories Co., Dayton, 3 No. 8245 Delco Liberty "12" generator assemblies, $94.05.
Dayton Engineering Laboratories Co., Dayton, 1 Liberty "12" rotor brush and spring, Delco system, $0.25.
Dayton Engineering Laboratories Co., Dayton, 100 distributor brush and spring assembly No. 12712, for Delco system on Liberty "12," $3.25.

Contracts

Dayton Engineering Laboratories Co., Dayton, 4 distributor brush and spring assembly No. 13712, for Delco system, Liberty "12," $0.13.
Dayton Engineering Laboratories Co., Dayton, 1 Delco generator, No. 8245, Delco system on Liberty engine and 1 voltage regulator No. 8542, Delco system, on Liberty engine, $36.05.
Dayton Engineering Laboratories Co., Dayton, 1 Delco switch No. 8408 and 2 distributor assemblies with coils. 12229; Delco system on Liberty "12," $70.95.
Dayton Engineering Laboratories Co., Dayton, 6 No. 12602 armature assemblies, Delco system on Liberty "12"; 6 No. 12616 field-coil assemblies, Delco system on Liberty "12," $63.42.
Splitdorf Electric Co., Newark, 100 magneto parts, $1,430.
Dayton Engineering Laboratories Co., Dayton, 12 distributor brushes No. 13712 (Delco on Liberty "12"), $0.39.
Dayton Engineering Laboratories Co., Dayton, 14 items Delco parts Liberty "12," $40.44.
Dayton Engineering Laboratories Co., Dayton, 4 items of Delco parts on Liberty "12," $92.54.
Dayton Engineering Laboratories Co., Dayton, 70 ignition switches No. 8408 Delco (Liberty "12"), $367.50.
Dayton Engineering Laboratories Co., Dayton, 25 breaker arm assemblies No. 12890 (Delco system on Liberty "12"), 25 distributor cams No. 12751 (Delco system on Liberty "12"), $29.50.
Nordyke & Marmon Co., Indianapolis, 100 No. 12515 crankshaft assemblies Liberty "12," $19,789.20.

—

WASHINGTON, Feb. 3—The following orders have been placed by the Motors Division, Quartermaster Department:

B. F. Goodrich Co., Akron, 797 casings and tubes, $11,491 29.

Peerless Motor Car Co., Cleveland, 1 lot spare parts, $19,923.74.

A. J. Detlaf Co., Detroit, 350 clutch assemblies $29,250.

Standard Motor Truck Co., Detroit, 225 standard 3½ chassis, 225 extra bodies, $695.-250.

Kelly-Springfield Tire Co., Cleveland, 100 casings and 1,050 tires, $30,362.

Troy Wagon Works, Troy, Ohio, 350 No 212 trailers, $372,750.

Kelly-Springfield Tire Co., Cleveland, 2,560 solid-pressed tires, $102,144.

Trailmobile Co., Cincinnati, storage agreement entered into provides that contractor receive as compensation 25 cents per day for each article stored, payable upon final delivery f. o. b. Cincinnati. Ordnance Nos. 12308 and 2226 ME.

Great Britain to Continue War-Time Restrictions on Automobile Apparatus

(*Continued from page* 290)

from the Board of Trade is permission to import a couple of chassis to be used for exhibition purposes only. These must not be sold under penalty of a severe fine. Most of the importers have already taken advantage of this ruling and are importing show or exhibition chassis. The same is true of commercial trucks, and will undoubtedly apply to farm tractors.

The importers are having a harder load to carry now than during the war. War orders have stopped and their men are returning from the army and are demanding their old jobs and efforts are being made to take all of them back. The repair work is increasing and the demand for spares is four times what it was in December. This assures good business for the repairshops, but the returning sales organizations have not a bright future for immediate employment.

But the importers have yet another load on their shoulders. Many of them have held together their entire dealer organizations throughout the British Isles. It is nothing short of wonderful how this has been done. One large importer, with nearly 150, has not lost a single dealer in four years. They have all had war work and those who went to war had their business carried on by others. Some of them have become manufacturers of no mean stature. One case in point is a Liverpool dealer who during the war has had 1000 employees and had two or three manufacturing plants. He has been manufacturing airplane wings as well as other parts.

Now that the war is over, these dealers are anxious to get back into business. Their war trade has ceased and repair work is now their only source of revenue excepting the sale of used cars. Every day the importers are literally besieged by these dealers, and they in turn are getting more inquiries than they have received for four years regarding post-war models, car prices, possible dates of delivery, etc.

The recent decision announced by the Board of Trade to continue the total prohibition order on imports is very disquieting to this army of dealers, who feel that as business men who built up legitimate businesses before the war and took their part during the war, that now they are not being fairly treated, and not given that business co-operation which they feel the Government owes them.

While these dealers are marking time the dealer handling British cars is little better off. His factory has been on war munitions since 1914, and has no cars on hand. All he has regarding post-war models in most instances are assurance of deliveries in August and September and in some cases October. Few of the British factories have as yet quoted prices, and but a small percentage of them have issued specifications of post-war models. There are exceptions, notably concerns that have been building cars during the war for army use, and one or two others who have post-war models ready and hope to make deliveries in April or May.

As to the attitude of the new Parliament on the importation of automobiles in the next year, nothing definite is known, but the decision of the Board of Trade is so explicit that there is no room for doubt. The Board of Trade ruling was made after the new Cabinet was formed, and Sir Albert Stanley, the president, is an appointee of the present Cabinet. In view of this, it can only be interpreted as the ruling of the new Cabinet, and as such will stand for some months at least.

There were elected to the new Parliament not fewer than a round dozen of members from the British manufacture. These twelve in nearly every case can be looked upon as protectionists. These members in nearly every case are connected with nearly all of the largest makers. This situation argues for a possible continuation of the restriction of imports. These makers have a strong case. They have been out of production for four years. Some have not been permitted to develop post-war models, and it is almost a certainty that the Government will protect these manufacturers until they can get back on their feet and get into production.

What will take place when the restrictions are removed and perhaps a duty imposed no one can tell. It is certain that free trade will not come back so far as motor cars are concerned. With twelve protectionists in Parliament from the automobile industry, and from the manufacturers generally of higher priced cars of small production, there is not good prospects for a continuation of free imports of automobiles into the British Isles.

No objection can possibly be raised to any protectionist policy on the part of Great Britain. France has her import duty of 70 per cent, America has her 45½ and 30 per cent custom duties and the British maker has every right to ask for a share in the same kind of protection. It is not against an import duty that the British importer has ground for complaint, but against an unknown period of continued total prohibition.

Capt. Westmoreland Returns to States

NEW YORK, Feb. 3—Captain H. E. Westmoreland, who has been adjutant of the Air Service Replacement Concentration Barracks No. 3 at St. Maxient, France, for the past eighteen months, is back in the United States. He was for a number of years Southwestern manager for the McQuay-Norris Mfg. Co., St. Louis, with headquarters in Dallas. His future plans are not yet determined.

—

W. B. Wood, for 17 years Detroit manager for Fairbanks, Morse & Co., has joined the sales force of the Commerce Motor Car Co., Detroit, to represent it in western territory.

—

Fred I. Tone, formerly with the Marion Co., Indianapolis, and Willys-Overland Co., Toledo, is now chief engineer of the United States Ball Bearing Mfg. Co., Chicago.

—

Ray A. Long is back at his old post as chief engineer for the Columbia Motors Co., Detroit. While in government service, from which he was just discharged, he helped develop the Militor Four-Wheel Drive truck.

—

J. M. Case, former sales and advertising manager of the United Motors Co., Grand Rapids, has become advertising manager of the Garfield Motor Truck Co. of Lima.

—

G. B. Rickenbaugh, who has been connected with the Irving National Bank for the past two years, was recently elected vice-president and general manager of the Scott Corp., which has general offices in Paris and London, with the main office in Aeolian Hall, New York.

—

Herb Flint, Detroit, former distributer of Hupp motor cars in Michigan, is now Western sales manager of the Abbott-Downing Truck & Body Co. of Concord, N. H.

—

C. L. Fox has been made sales manager of the Saxon Motor Car Co., Detroit. He has been with the company since its incorporation.

—

E. S. Gellatly, for several years vice-president of the Indian Refining Co., New York, also in charge of its Havoline oil advertising, severed his connection with that company on Jan. 15 to go with the Illinois Zinc Co., New York, where he will be in charge of the formation and organization of a new department.

—

Elbert Warford, who has been in the aviation service, has returned to his former position as advertising manager of the Seattle branch of the B. F. Goodrich Rubber Co.

—

Elmer Sperry to Address S. A. E.

CLEVELAND, Feb. 3—Elmer Sperry, inventor of the gyroscope, will address the March meeting of the Detroit Section Society of Automotive Engineers.

Men of the Industry

Changes in Personnel and Position

Don T. Hastings, M. E., has been appointed manager of the Chicago office of Rex W. Wadman, Technical Advertising Specialist, and is in charge of all the business of the concern in the Middle West.

—

Charles A. Mayne, formerly of the Firestone Tire & Rubber Co., Akron, who was connected with the Republic Motor Truck Co. of Alma for the last few months, has gone to South America, where he will represent that company.

—

L. E. Colgrove, former Grand Rapids distributer of Hudson cars, has returned from the army and is now selling Cadillac machines for the Becker Sales Co. of that city.

—

J. P. O'Brien has been appointed district manager in Chicago of the central territory of the Anderson Electric Car Co. He has been associated with the company for the past six years.

—

C. Haines Wilson, treasurer and general manager of the C. R. Wilson Body Co., Detroit, recently left for a six weeks' trip to Pasadena, Cal.

—

W. H. Luhrs, general manager and member of the Board of Directors of the General Aluminum & Brass Mfg. Co., Detroit, has severed his connections with that company.

—

L. E. Lyons, for the past six years sales engineer of the axle division of the Sheldon Axle & Spring Co., has resigned to become associated with the B. F. Everitt Co., Detroit.

—

Fred E. Dean has become associated with the Allied Metal Sales Corp., New York, as Western sales manager, with headquarters in Detroit.

—

Frank R. Ryan has been added to the sales force of the Chicago office of the Roller-Smith Co., New York. Previously he was connected with the testing department of the Commonwealth Edison Co. and the Krehbiel Co., consulting engineers, Chicago. For the past six months he has been in the signal corps. He succeeds Charles H. Nicholson, who since his return from service is in charge of the company's Detroit office.

—

F. A. Haines has been promoted from factory manager to general manager at Dodge Bros., Detroit. A. Z. Mitchell, his former assistant, succeeded him as factory manager.

Barney Oldfield Becomes Tire Maker

CHICAGO, Jan. 31—Barney Oldfield, the veteran racing driver, has branched out into the industry as the head of a new tire concern known as the Oldfield Tire Co. He says this definitely marks his retirement from racing.

—

J. H. Kelly, formerly production manager of the Hudson Motor Car Co., Detroit, is now general manager of the Cole Motor Car Co., Indianapolis.

—

Lieut. D. W. Bay has returned to his former position as sales engineer, Hyatt Roller Bearing Co., Detroit, in charge of Illinois, Wisconsin and the Northwest, with offices at 2715 South Michigan Avenue, Chicago. For the past 15 months he has been in the Motors Division, Department of Production, Quartermaster Corps.

—

William K. Swift, Philadelphia, has become associated with the sales department of the Bound Brook Oil-less Bearing Co., Bound Brook, N. J.

—

Harry H. Hawke, formerly connected with the De Luxe Automobile Co., St. Louis, has been made general sales manager of the Traffic Motor Truck Corp.

—

Walter Wilmot, former manager of the Detroit Automobile show, is now manager of the Minneapolis automotive show, which opens Feb. 15.

—

J. H. W. Mackie, who resigned as sales manager of the Saxon Motor Corp., is now general manager of the Payne Motor Car Co., Minneapolis.

—

Major John L. Bender has joined the Anderson Forge & Machine Co., Detroit, as sales manager. For the past 15 months he has been the military member of the Priority Committee of the War Industry Board at Washington.

—

Ford Enters Tire Field

DETROIT, Feb. 3—Henry Ford is now making rubber tires for his cars. The Ford Motor Co. has built and is operating a small tire factory producing on a small scale. Only a few tires have been made to date, but plans call for extensive manufacture.

—

Advertising Manager Dies at Desk

BOSTON, Feb. 4—George Burkle, advertising manager of Gray & Davis, Inc., died of heart failure at his desk on Friday, Jan. 31.

—

Lansing Automotive Leader Dead

LANSING, Jan. 30—Harry E. Bradner, general manager of the Auto Body Co. since that corporation was started in 1901, and later president of the concern until a few weeks ago, died of pneumonia last week. He was also vice-president of the Duplex Truck Co., the Gier Pressed Steel Co. and the Auto Wheel Co., all of Lansing. The Auto Body Co. was started with a capital stock of $20,000, which recently was increased to $2,000,000.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Studebaker Additions Will Increase Working Population

SOUTH BEND, Feb. 3—At a dinner tendered him by the South Bend Chamber of Commerce, Jan. 30, A. R. Erskine, president of the Studebaker Corp., stated that within a few months Studebaker cars will be built completely in South Bend, as well as in Detroit, the production totaling 500 complete cars per day, when the extension plans are in operation.

The factory additions caused by the Government contracts which were under way when the armistice was signed, in which shells, tractors and other munitions were to be produced, will form the beginning of the extension, which will cover 61 acres, and provide 4,000,000 sq. ft. of floor space, requiring from 7000 to 12,000 employees. The new equipment includes everything from a foundry to the final car assembling.

The whole plan, however, hinges on the housing question, for this expansion will mean doubling the present working population of the city, and the Chamber of Commerce last night started on plans for providing homes for these people. Housing facilities for 10,000 men and 2000 women will have to be provided, one-half of whom will be at work by Dec. 1 of this year and the other half six months later.

No Drop in Packard Prices

DETROIT, Jan. 30—The Packard Motor Car Co. is extensively advertising the fact that there will be no change in Packard prices. The company states that as there was no rise in Packard prices during the war period, there is consequently no leeway for reduction at this time.

300 Dodges Turned Out a Day

DETROIT, Jan. 31—Dodge Brothers are turning out 300 machines a day. A portion of the plant is still engaged in war work. The Dodge car, being one of the standard makes chosen by the army, is being still purchased by the government. The company is also working on parts orders for the repair and maintenance of its machines in federal service. There are 10,000 men on the payroll. When at full capacity 18,000 men are employed.

Maxwell Now at Daily Rate of 150

DETROIT, Jan. 31—The Maxwell Motor Car Co. is producing 150 cars daily, and expects to increase this output materially in the immediate future.

Dort Production Normal Again

FLINT, MICH., Jan. 30—The Dort Motor Car Co. has about finished government work and is back at normal car production. The plant is turning out 40 cars daily, and its 1919 production schedule calls for 15,000 machines. The next three or four weeks will see the last government job completed. This winds up over $3,000,000 of war contract work which called for the manufacture of "AA" trucks, trailers, truck "C" bodies and cutting boards.

Salvaged Scrap Saves $3,000,000

AKRON, Feb. 1—An indication of the conservation methods of the Goodyear Tire & Rubber Co. may be gained from the fact that the by-products during the year salvaged scrap and waste material to the amount of $3,000,000.

Curtiss Advertising Department at Garden City

BUFFALO, Feb. 1—The advertising department of the Curtiss Aeroplane & Motor Co. has been moved from the Buffalo plant to Garden City, L. I.

Amazon Rubber Co. Issues Extra Dividend

AKRON, OHIO, Jan. 31—The Amazon Rubber Co., which held its annual meeting Saturday, showed an increase in business during 1918 of 85 per cent over 1917. An extra dividend of 12½ per cent was issued. Officers for the coming year were elected as follows: President, Albert Kroehle; vice-president, J. A. Burger; treasurer and general manager, L. J. Schott; secretary and general superintendent, L. F. Smith.

Grant Reduces Price $130

CLEVELAND, Feb. 1—The Grant Motor Car Corp. this week issues a new schedule of prices for Grant-Six cars, to take immediate effect. The new prices reveal a reduction of $130 on each machine, as follows:

Model	New Price	Old Price
Grant-Six touring car....	$1,120	$1,242
3-passenger roadster.....	1,120	1,242
3-passenger coupé........	1,625	1,755
All weather sedan.......	1,645	1,775
Demountable sedan......	1,400	1,530

The Grant corporation guaranteed its dealers against a price decrease up to May 1.

Ward LaFrance Drops Prices

ELMIRA, Feb. 3—The Ward LaFrance Truck Co. has reduced the price of its 2-ton truck $150 and of its 3½-ton truck $175.

	New Price	Old Price
2-ton truck........	$3,350	$3,500
3½-ton truck......	3,750	3,925

Acme Truck Scheduled for 1400 in 1919

CADILLAC, Jan. 30—The Acme Motor Truck Co. is producing approximately four trucks daily. The production schedule for this year calls for the manufacture of 1400 trucks. The 1919 machine embodies no radical design changes, but has been improved upon in a number of minor respects. The company is anticipating no price reduction, and is guaranteeing its distributers against a cut.

Changes in Executive Force of Pennsylvania Rubber

JEANNETTE, Jan. 31—At a special meeting of the Board of Directors of the Pennsylvania Rubber Co. on Jan. 27, George W. Daum was elected second vice-president in charge of production, and A. H. Price was elected second vice-president in charge of sales. James Q. Goudie, formerly sales director in charge of the Middle West district, who represented the company in Washington regarding its Government business, was elected general sales director, in charge of branch sales, with headquarters at Detroit.

New Aultman-Taylor Tractor Model

MANSFIELD, OHIO, Feb. 3—The Aultman & Taylor Machinery Co. is building a new model tractor to be known as the 22-45. This will supersede the former models 18-36 and 22-50. Plans are being made to get this model on the market in a very short time.

No Price Reduction in Saxons

DETROIT, Jan. 31—The Saxon Motor Car Corp. has assured its dealers that it will protect them against a reduction in the price of its cars. Prices will positively not drop before June 1. In case the company finds it necessary to cut prices, the new contract which Saxon purchasers sign calls for an appropriate refund.

Government Airplane Factory for Fisher Body Corp.

DETROIT, Feb. 3—Fisher Body Corp. is now endeavoring to lease or purchase the airplane factory adjoining its plant, built by the Government for aircraft production. Federal officials are now in the city. An inventory and survey of the plant is under way, and the matter will probably come to a head in the course of a few days.

Paterson to Increase Production

FLINT, MICH., Jan. 30—The W. A. Paterson Co., makers of Paterson 6-cylinder cars, will increase daily production about April 1. This company is now running 20 cars per week and is preparing to deal more extensively in the foreign market. The new 1919 car varies but slightly from the 1918 model. The company does not plan a price reduction, and is guaranteeing to give distributers 60 days' notice if such a course is decided upon.

Allen Motors Resuming Pre-War Production

FOSTORIA, OHIO, Jan. 31—The Allen Motor Co. is fast getting back to prewar production.

Grant to Make 12,000 Cars

CLEVELAND, Jan. 30—The Grant Motor Car Corp. plans the production of 12,000 cars during the coming year. Twenty-five machines are being turned out daily, but plans for increased production are already in effect.

Calendar

ENGINEERING

S. A. E. Meetings

March 5 — Minneapolis Section, S. A. E.—Hotel Radisson. "Tractor Service and Sales."

MOTOR SHOWS

Feb. 1-15—New York. Automobile Dealers' Assn. Charles A. Stewart, Manager, Hotel Woodward, Broadway and 55th St.

Feb. 6-15—San Francisco, Cal. Third Annual Pacific Automobile Show, Motor Car Dealers' Assn. of San Francisco, Exposition Auditorium. G. A. Wahlgreen, Manager.

Feb. 10 - 15 — Rochester, N. Y. Rochester Automobile Trades Assn., Exposition Park. George C. Donahue, Manager.

Feb. 12-15—Defiance, O. Second Annual Show under auspices of Defiance Automobile Dealers' Assn.

Feb. 15-22—Newark, N. J. N. J. Auto Exhibition Co. Calude Holgate, Manager.

Feb. 15-22 — Cleveland, Ohio. Cleveland Auto Show Co. Fred H. Caley, Manager.

Feb. 15-22—Minneapolis, Minn. Minneapolis Auto Trade Assn. Walter B. Wilmot, Manager.

Feb. 15-22—Albany, N. Y., Albany Automobile Dealers' Assn. State Armory.

Feb. 16-22—Waco, Tex. Henry B. Marks, Manager.

Feb. 17-22—St. Louis. St. Louis Auto Mnfrs. & Dealers' Assn. Robert E. Lee, Manager.

Feb. 17 - 22 — Louisville, Ky. Louisville Auto Dealers' Assn.

Feb. 17-22—Des Moines, Iowa. Tenth Annual, Des Moines Automobile Dealers' Assn. C. G. Van Vliet, Manager.

Feb. 17-22 — Pittsfield, Mass. Pittsfield Automobile Dealers' Assn., State Armory. James J. Callahan. Manager.

Feb. 17-22 — Passenger Cars; Feb. 24-27, Trucks—South Bethlehem, Pa. Lehigh Valley Auto Shows Co. J. L. Elliott, Manager.

Feb. 17-22—Grand Rapids, Mich. Grand Rapids Automobile Business Assn. E. T. Conlon, Manager.

Feb. 17-22—Seattle, Wash. Cars. Motor Car Dealers' Assn., State Armory. A. G. Schaeffer, Manager.

Feb. 18-22—Baltimore, Md. Baltimore Automobile Dealers' Assn. and Automobile Club of Maryland, Fifth Regiment Armory, H. M. Lucius, General Manager.

Feb. 18-22 — Oklahoma City, Okla. Automotive Show. R. H. Braun, Manager.

Feb. 19-22 — Evansville, Ind. Cars, Evansville Automobile Dealers' Assn. Coliseum.

Feb. 22-Mar. 1—Hartford, Conn. Hartford Automobile Dealers' Assn., Inc., Broad Street Armory. Ben. F. Smith, Manager.

Feb. 22-Mar. 1—Atlantic City, N. J. Auto Trades Assn. of Atlantic City.

Feb. 22-Mar. 1—New Castle. Pa., Lawrence County Association of Automobile and Accessory Dealers.

Feb. 23-March 1—Cedar Rapids. Auditorium, Automobile Dealers' Assn.

Feb. 24-Mar. 1—Burlington, Ia. Second Annual.

Feb. 24-March 1—Kansas City, Mo.—Kansas City Motor Dealers' Assn. E. E. Peake, Manager.

Feb. 24-Mar. 1 — Springfield, Mass. Automobile Dealers' Assn. Harry W. Stacy, Manager.

Feb. 24-Mar. 1—Portland, Ore. Ninth Annual Dealers' Motor Car Assn., Automobile Palace. M. O. Wilkins, Manager.

Feb. 25-Mar. 1 — Erie, Pa., United States Garage.

Feb. 26-Mar. 1—Mason City, Ia. Fifth Annual. Mason City Auto Show Assn.

Feb. 26-Mar. 1—Madison, Wis. Seventh Annual. Automobile Dealers' Division of Madison Assn. of Commerce. Union Transfer Bldg.

Feb. 26-Mar. 1 — Quincy, Ill. Cars. Quincy Automobile Trade Assn. Armory.

Feb. — Wheeling, W. Va. Automobile show at Market Auditorium.

March 1-15—New York Aeronautical Exhibition. Manufacturers' Aircraft Assn., Madison Square Garden and 69th Regiment Armory.

March — Scranton. Pa. Thirteenth Regiment Armory, Scranton Automobile Assn.

March—Utica. N. Y. Utica Motor Dealers' Assn. W. W. Garabrandt, Manager.

March—Philadelphia. Pa. Philadelphia Automobile Trade Assn. Passenger cars.

March 1-8—Detroit, Mich. Detroit Automobile Dealers' Assn. H. H. Shuart, Manager.

Mar. 3-5—Quincy Ill. Trucks and Tractors. Armory.

March 3-8—Columbus, O. Columbus Automobile Show Co., Memorial Building. W. W. Freeman, Manager.

Mar. 3-8 — Muskegon, Mich. Third Annual, Armory, Muskegon Lodge No. 274, B P. O. E. John C. Fowler and George M. Friant, Managers.

Mar. 3-8—Scranton, Pa. Ninth Annual, 13th Regiment Armory, Scranton Automobile Assn. Hugh B. Andrews. Manager.

March 3-8—Buffalo, N. Y. Buffalo Automobile Dealers' Assn.

Mar. 5-8—Lancaster, Pa. Automobile Trade Assn., Rowe Motor Co.'s Bldg. R. W. Shreiner. Manager.

Mar. 8-15 — New Brunswick, N. J. Armory, New Brunswick Motor Trade Assn. William Kuehle, Manager.

March 10-15—Paterson, N. J. Paterson Automobile Trade Assn., Fifth Regiment Armory. H. MacGinley. Show Manager.

March 10-15—Syracuse, N. Y. Syracuse Automobile Dealers' Assn. Harry T. Gardner, Manager.

March 10-15 — Omaha, Neb. Fourteenth Annual, Omaha Automobile Trade Assn. Auditorium. Clark G. Powell Manager.

March 12-19—St. Joseph, Mo. Sixth Annual. St. Joseph Automobile Dealers' Assn.

March 15-22 — Boston, Mass. Boston Automobile Dealers' Assn. Passenger cars only. Chester I. Campbell. manager.

March 15-22—Harrisburg. Pa. Harrisburg Motor Dealers' Assn., Overland Warehouse. J. Clyde Myton. Manager.

March 17-22 — Great Falls. Mont.—Montana Automobile Distributors' Assn.

March 19-22—Norfolk. Neb. Norfolk Automobile Show Assn.

March 22-29—Pittsburgh Automobile Dealers' Assn. of Pittsburgh. John J. Bell. Manager.

March 22-29. Passenger Cars: April 1-5. Trucks—Brooklyn. Brooklyn Motor Vehicle Dealers' Assn. I. C Kirkham, Manager.

Mar. 24-29 —Greenfield, Mass. Greenfield Automobile Dealers' Assn., State Armory. James J. Callahan (Pittsfield) Manager.

Mar. 24-29—New Orleans, La. Henry B. Marks, Manager

Mar. 26-29—Watertown, N. Y. Tenth Annual, State Armory, Automobile Dealers, Inc. Arthur E. Sherwood, Manager.

Third week March—Trenton, N. J. Trenton Auto Trade Assn. John L. Brock. Manager.

April 5-12—Montreal, Can.—National Motor Show of Eastern Canada, Victoria Rink. T. C. Kirby, Manager.

Not decided—Bridgeport, Conn. Auspices of City Battalion. B. B. Steiber, Manager.

Not decided—Indianapolis, Ind. Indianapolis Auto Trade Assn. John B. Orman. Manager.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

TRACTOR SHOWS

Feb. 15-22—Minneapolis, Minn.

Feb. 18-22—Wichita, Kan. Annual Mid-west Tractor and Thresher Show. Wichita Tractor and Thresher Club. Forum.

Feb. 24-March 1—Kansas City. Mo. Fourth Annual Tractor Show. Sweeney Building, Kansas City Tractor Club. Guy H. Hall, Sec.

RACES

Mar. 15—Santa Monica, Cal. Speedway.

May 17—Uniontown, Pa., probably 112½ miles.

July 5—Cincinnati, O., Speedway.

CONVENTIONS

Feb. 19—New York. 13th annual banquet of Aero Club of America, Waldorf-Astoria

Feb. 25-28—New York. Sixteenth Annual Convention. American Road Builders' Assn.

Feb. 25-28 — Ninth American Good Roads Congress and 16th Annual Convention of the American Road Builders' Assn. Hotel McAlpin, New York.

Apr. 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

Buda Has Three New Tractor Engines

HARVEY, ILL., Feb. 1—The Buda Co. will exhibit at the Kansas City tractor show, to be held from Feb. 24 to March 1, three new types of heavy duty tractor engines. These will be of the same general design as the 4¼ x 5½ in. engine which made a 103-hour non-stop run at the Salina tractor demonstration last summer. They have been developed and tested during the past year.

The largest of the new models is a 4-cylinder, 5 x 6½ in. bore and stroke engine having a piston displacement of 510.5 cu. in. Another, also a 4-cylinder engine, has a bore and stroke of 4½ x 6 in. They are block cast, with removable heads and full pressure lubrication.

It is stated that these engines are especially suited for multiple plow work in new soil, on large acreage and in the heaviest kind of duty, using low grade or heavy fuels.

Jackson May Quit Passenger Car Field

JACKSON, Feb. 1—The Jackson Automobile Co. will not place a passenger car on the market this year. While the company is still undecided on its future policy and will make no formal statement at this time, it is understood that it proposes hereafter to devote its entire time to the production of trucks. The company is just winding up a large government shell contract.

New Die Casting Co. for Milwaukee

MILWAUKEE, Feb. 3—The Wisconsin Die Casting Co. has been incorporated here with a capital stock of $25,000 to engage in the general die casting business. The incorporators include Gustave R. Hurz, Julius O. Roehl, attorney, and Fred H. Koch.

Lewis Steel Products Co. Changes Hands

TOLEDO, Jan. 30—The controlling interest in the Lewis Steel Products Co. has been purchased by a group of Detroit and Cleveland parts manufacturers. Additions to the plant will be started at once and a new plant will be erected later. George L. Lewis, president and founder, has disposed of all his interest in the concern, and A. R. Clas, for nine years with the Falls Motor Corp., of Sheboygan, has taken over the management. It is understood that Mr. Lewis will organize another company to manufacture automobile parts.

Champion Dependable Spark Plugs

Wins Out in Government's Severe Shock Test

At the factory of the Chalmers Motor Car Company, of Detroit, Michigan, the United States Government was conducting a most exacting ignition test on the Holt-Caterpillar Tractors, used in war-work for hauling cannons, caissons, etc.

With motor at high speed under heavy load, the spark plugs at sizzling heat were doused with a bucketful of cold water.

This most severe test had not the slightest adverse effect, the operation of the motor continued perfectly, not a spark plug "missed" even temporarily.

Every motor car owner has, in this test, irrefutable proof of the hardiness and efficiency of Champion Spark Plugs.

Every Champion Spark Plug dealer has, in this test, additional proof of the wisdom of recommending the Champion Spark Plugs especially designed for every type of motor.

Champion Spark Plug Company, Toledo, Ohio

Champion Spark Plug Co. of Canada, Limited, Windsor, Ontario

European Expansion Under War Pressure

Post-War Models Not Ready—Electric Starting and Lighting Universal—Huge Factory Enlargement

Part I

By David Beecroft

LONDON, Jan. 21—Two months have not been sufficient for European automobile manufacturers to get converted from war to a peace program. That time has not been long enough for many to decide on what their peace program shall be. For more than 4 years they have worked on a war program only. Their peace organizations have been completely disrupted. With many, their manufacturing organizations have been disrupted as compared with 1914. Some have been very largely without engineering organizations since that date. Others have lost many from their organizations who were heads of departments in 1914. The peace manufacturing momentum ceased to exist long ago.

Factories were placed under government control in most instances and were largely prevented from going ahead with post-war activities. Many of the British factories were expressly forbidden from utilizing any of their engineers in the development of post-war models.

Few Completely Converted

There were a few factories that were turned entirely from automobile manufacture to aircraft. A case in point is that of the Sunbeam, whose automobiles have been manufactured during the war and used as officers' cars; but these have not been built in the Sunbeam factory, but in other British factories, while the Sunbeam company has had to devote its energies almost exclusively to the development and production of engines for aircraft uses.

Industry Not Ready for Peace

What is true of this factory is true of many others to a very great extent, and the miraculous would have happened if these factories had been able in a month or 6 weeks to turn from peace into war and get on a development basis. In every factory, and in practically every industry, the general comment is that it was relatively easy to move from peace into war in 1914 and 1915, but it is a herculean task to transform the greatly increased factory capacities from war into peace.

It is true of Great Britain, France and Italy that up until Armistice day they had not contemplated an early peace and were going ahead on the basis of at least one more year of war, and perhaps 18 months.

There was no slowing up of development, while many factories had been doubled, tripled, quadrupled, and in some cases increased tenfold in manufacturing capacity; the work of expansion was not completed.

New buildings were going up on every hand.

Some factories had additions under operation which would give a 25 per cent further increase in capacity. This increase was all based on a war program. Peace did not enter into it.

Suddenly, on Nov. 11, this came to an unexpected end. In the short space of one hour the entire program was changed. The active belligerent stage of war was over, and these industries for the first time since 1914 thought of peace. For the first time they were face to face with the stupendous problem of passing from the stage of war activity into a peace program.

Up to that time many had not given it any consideration. It is true the leaders of these industries had been analyzing the situation, but help was scarce and demand for production so high and Government insistence on a 100 per cent war program so intense that nothing active had been done in 80 per cent of the cases.

Some Factories Favored

There are exceptions to this condition. Some of the factories received more favorable treatment from the Government. The exact reason for this is not known. During the war a few of them were able to work along their previous lines. For example, the Vauxhall company in England was manufacturing its cars for war use during the entire period and so is in a preferred position to talk deliveries, specify dates and quote prices. It has even been able to develop a post-war model which has passed through the development stage and is ready for production.

In Italy, Fiat has been manufacturing both passenger cars and trucks in tremendous quantities during the war and has also been developing post-war models and has on hand great volumes of material with which to push these into production. Fiat's post-war models have been tested out for many months. They are in production, and a program for world-trade is moving ahead.

In France, Renault, which has had an amazing increase in manufacturing capacity, has been permitted to go ahead in the development of post-war models and has these well developed and almost ready for production.

In England, Crosseley has been devoting a large percentage of its factory to the production of a light high-speed van for the Royal Air Force, the chassis being a development of the pre-war model. Its manufacturing organization on this model has not been molested, but very greatly increased, so that its capacity of fifty cars a month before the war has been increased to 250 per month now, and it is into production on a program of 3000 cars per year of its 25-30-hp. type, and is getting ready for a program of 7000 additional on its new 15-hp. model, which is a development of the war and is counted as one of Great Britain's post-war models.

20% Will Have Big Start

With many other companies the conditions are similar, and at least 20 per cent of the industry in Great Britain, France and Italy is going to have a big start over the remaining 80 per cent in the question of production and getting back into the market.

From a canvass of over forty firms manufacturing automobiles in England, the conclusion is that very few are ready to quote chassis specifications, delivery dates. or prices. They are all working on post-war models. It would be impossible to make deliveries before October or November, and, owing to the uncertainty of the material market, the quoting of prices was out of the question.

Several stated they were endeavoring to produce as good and cheap a car as it was possible to produce. Others frankly stated that their post-war prices on continued models were 50 to 75 per cent higher than 1914 prices, due to increased cost of labor, higher cost of materials, and to this might be added the expense these organizations must face in rebuilding their entire factory scheme for automobile production.

There will not be a comprehensive display of post-war models in Europe until the Olympia Exposition, which is scheduled to take place in London in November, and even at that time several of the post-war models will only be in a semi-completed stage of development.

No Low-Priced Models

France is holding in March her great industrial fair at Lyons, where most of the French and Italian manufacturers, as well as some of the British and American, will exhibit. In a few cases there will be post-war models exhibited by such firms as Fiat, Renault, Crossley, Vauxhall, Austin, Argyle, Peugeot, and one or two others.

The majority of the remaining firms will show models that are continuations of pre-war types. The Lyons Fair is not merely an automobile exhibit, but an industrial exhibit of all French industries, and marks France's initial step in her efforts to get into industry. The world will have to wait until November to get a correct measure of what Europe is going to build in the way of post-war models.

It is possible at present to outline in a general way what is coming through in the post-war model field. *One thing is certain, namely, that there is not going to be a landslide movement into the low-priced cars selling at* $1,000 *or thereabouts and which models will serve as rivals for the American car in that field.*

For the present Great Britain has almost deserted the cheap car field. There is no tendency as yet for new models that will compete with the cheap American car. In France, Renault, with a new production job which is expected to sell at about $1,000, looks like the most aggressive factor in American competition. Fiat is a close second, although its price is not yet definite.

British Cars High Priced

The majority of the British factories still incline to the high-priced automobile. As an example of this, Daimler will sell as its cheapest model a 30-hp. six-cylinder car at $4,500. This same model formerly sold at approximately $3,800. Napier will market a six-cylinder car at $5,000. One of the Vauxhall models lists at $5,900, and the other at a little less. Austin has a new model, a real post-war type, which will sell at approximately $2,000. Rover has a model which before the war sold at $1,750 and is now listed at over $2,000.

Very few announcements of prices have been made in the smaller field. The 10-hp. four-cylinder Singer is listed at $1,375, and a Belsize at $2,100 which formerly sold at approximately $1,500. The B.S.A. small car which was brought out by the Birmingham Small Arms Co., as the adaptation of the Ford in England but on an expensive design basis, has been discontinued, and this large concern apparently gone out of what might be interpreted as the low-car field.

In France the Citrogen company, a new organization, which previous to the war was a large manufacturer of gears, but which during the war grew to be one of the greatest factories in Paris, is planning to go into a cheap car production, but has nothing definite as yet.

All Europe is going into the equipment of post-war models with electric starting and lighting as standard. There will not be a single exception to this, even in the cheapest cars. Every concern has decided on this policy, and accessory manufacturers are under way in the production of generators, starting motors and batteries.

The question of standardizing on these parts has already been taken up in Great Britain by the Institution of Automobile Engineers; committees have been formed for starting battery standardization, and the sentiment is that plate dimensions will be standardized. The sentiment is to work as close as possible to American standards.

With electric starting motors outside dimensions only are going to be standardized at present. The committee having this work in hand is making good progress.

The committee having the standardization work of electric generators in charge has not started on this job as yet.

Starting motors are going to be mounted in practically the same way as in America, and in the majority of cases will drive by pinion into a ring of teeth on the flywheel. Already some of the large manufacturers have developed motor drives for this use.

Value-in-Head Design Increases

With regard to the generator, manufacturers are not so agreed. In the final post-war models they undoubtedly will be incorporated in the engine very similar to the American practice, but for the present not a few are going to be mounted on the front arms of the crankcase and driven by belt. Belt-drive will undoubtedly disappear as the development of the models crystallize. The case seems a parallel with the introduction of the magneto years ago in America when our early models were chain-driven.

There is every promise of considerable movement throughout England, France and Italy toward the valve-in-head design of engine. This may not appear in the first post-war models, but is receiving considerable attention by the leading engineers. The fuel question is so acute in all European countries that the increase of fuel efficiency is certain to have a very definite effect on engine design.

The reading of a paper in January by L. H. Pomeroy, Vauxhall engineer, on experiments with valve-in-head designs and its reception by the majority of the engineers in the country is an indication of what can be expected. The new four-cylinder Vauxhall with a horsepower rating of 30-98 is of this type, and is looked upon as one of the finest performing cars in Europe. Its cylinder dimensions are 98 by 150 mm. In Italy, while the valve-in-the-head design has not actually appeared, it was frankly admitted that it is under serious consideration. The same is true in France.

Aluminum Alloy Development

As suggested by Mr. Pomeroy in his address on valve-in-the-head design, one of the strong reasons for it being favored is the fact that it is much easier to mount the engine accessories, such as starting motor, generator, etc., with a valve-in-the-head design than with a T-head or L-head design. His experiments with valve-in-the-head design also established the point that with valves in this position diameter is not so great a factor and that intake gas velocities can be increased very greatly without any deterrent effect on the efficiency of the engine.

The use of detachable cylinder heads is under way and is destined to make considerable progress. It has attractions because of its manufacturing possibilities and also because of the fuel situation.

Great Britain has made wonderful strides in the development of aluminum-copper alloys for piston manufacture. This work has been pioneered by the aircraft development. The National Physical Testing Laboratory at Teddington, a suburb of London, has been working on this subject during the entire period of the war and has made great development. The aluminum alloy piston has come into general use and due recognition has been taken of its effect on the thermal characteristics of the engine.

Special Steels Developed

The development of a special grade of automobile steels was aggressively taken up by the British automobile makers and the steel manufacturers over 18 months ago. For a period of 11 months they concentrated on the development of twenty steels which were approved some months ago as standard automobile steels, and the steel manufacturers started production on them last fall. These had been adopted as standard steels by the Engineering Standards Committee, which is the national organization that finally decides on standards in all industries.

Once a specification or design is approved by this committee it is immediately accepted by all the manufacturers as a standard and is so considered in their complete manufacturing program. The sentiment was freely expressed that American steel specifications did not measure up to the requirements of the British manufacturer, and the new adopted list of steels is a result of the manufacturer's effort to put an automobile on as high a standard as possible.

This suggests the fact that there is throughout England no sentiment in favor of dropping from her high standard of material and workmanship that existed previous to the war. Her factories have learned great lessons in production. They have been filled with the best machinery, and some of the factories state they are doing machine costs lower than in America, yet notwithstanding this they are going to maintain their reputation for the very highest grade of workmanship and are going beyond pre-war standards in the use of high-grade materials.

No Decrease in Quality

The lessons of production have not blinded them to the desirability for a high-grade product. Good workmanship and the necessity for it have increased in Europe because of the war. All war products have to be made on a high standard of accuracy. The consequent aim was to produce the product that would give the best results. The production of the very best grade of ammunition permeated every factory and every home in England and France. Its objective of accuracy has impressed its lesson on the entire nation. At the same time the possibilities of production have been realized and appreciated. Production methods are going ahead, but there is going to be every precaution taken to prevent the sacrifice of quality for a little gain in production.

It was impossible during December when the Italian and French factories were visited, and during January when the British factories were visited, to gage correctly the possibilities of increased production in these factories on post-war models. Many of the companies had not ceased their war activities. Some of them will not be through with Government orders on aircraft engines for another 6 months.

Most of them have ceased the manufacture of shells, but several were still going on and expected to continue for several months on the building of airplanes of large bombing types, and on parts of aircraft engines and other lines of munitions.

It was unreasonable to look for production systems in factories that since the start of the war had been under Government control and were continuing on Government contracts. Much of the new machinery installed was installed especially for war work, and there was not to be seen a good deal of the multiple spindle type of machine

that is so generally used in America for production methods on automobile parts.

You looked in vain for progressive assembly systems, even with those companies that have been manufacturing cars for war uses. It was a little disappointing not to find well worked out progressive assembly systems in such factories. They are distinctly behind America in this respect.

There were three exceptions: Ford at Manchester has an assembly system as good as anything in the Ford factories in America. The large British truck manufacturer, the Associated Equipment Co., has a well worked out progressive assembly system in the form of what might be designated a traveling sidewalk which carries not only the chassis under assembly but the workers as well, so that the workers move along with the chassis or parts they are working upon.

Renault had perhaps the best example of progressive assembly on the continent in his aviation assembly room, where each engine is carried through assembly on a moving stand which is a conventional type mounted on wheels which travel in a U-track in the floor.

Little Progressive Assembly

In all of the other factories no effort had been brought into actual operation by way of progressive assembly. It was unreasonable to expect any such thing excepting in those factories that had been engaged on car production during the war. It must be remembered that America's great steps in production methods have been made since 1914 and that the majority of the European manufacturers have had little opportunity since then to come to America and study our methods.

In some of the accessories factories excellent manufacturing methods have been adopted. This is particularly true in some of the British magneto factories that have been developed under Government pressure during the war and which represent some of the most modern factories in existence. Everything modern has been installed. The lighting has been brought right to the side of the head of the worker where glare in the eye is impossible and where the greatest illumination possible on the work is obtained.

The workbenches and tables have been laid out with special regard for the work. Small assembly trays are in use with separate compartment to contain all of the parts used in the assembly of any part of the magneto. Where the condensers are being assembled there are glass sides to the working tables, so that there can be no possible interference by the wind or other agents in the speed of the work. Suitable foot rests are provided for the workers, whether women or men. The same applies to chairs. It would be almost impossible to conceive of any improvement that might be added in some of these factories.

Too Much Littering Up

There are some of the other factories where the fundamentals of production have not been studied and applied as they should. Not sufficient attention has been made to the clean-desk idea in assembly. You would see assembly benches where the parts are piled promiscuously along the center of the benches without regard to the rows of workers on the sides. Mental confusion can only follow such practices. Not a few of the manufacturers were aware of the handicap of such methods, but seemed to feel that under the stress of war they had not the available energy to revamp a system.

In some of the largest aircraft factories—and this criticism might apply to most of the factories, in the automobile, truck and aircraft industries—there is a lack of benches or racks, or crates, call them what you will, to carry the raw material or partly finished material awaiting at the different machines; and other racks to receive the material after it had been worked upon by the machine. There was too much throwing of parts on the floor or putting them in very inefficient boxes.

There was a general realization that throwing anything on the floor is inefficient. It was realized, too, that special racks for crankshafts, camshafts and all parts in the process of construction were desirable, but that the enormous pressure of expansion during the war had made it difficult to get into this aspect of production as many had desired to do. It must not be inferred that there were not in many factories very complete equipments in the way of racks and benches.

Electric Industrial Trucks Used

The use of industrial electric trucks is general in several factories, and in the majority of the others the factory managers had been endeavoring for nearly a year to get such, but were unable to do so. Fiat received its first half dozen of such trucks from American in December. They had been on order for more than a year. Several of the French factories had been trying to get such for months but without avail.

In the absence of these trucks there has sprung up a very general use of overhead trolleys for moving material and also the use of the miniature trolley system along the factory aisles. Very narrow gage steel rails are laid in the concrete flooring and hand trucks in trains of two or three are pushed along these tracks.

Where factory development has been enormously great, as in the case of Renault, which before the war had 4500 workers and now has 23,000, the use of motor vehicles to transport material from one building to another and into and through the buildings as well, has been developed. Renault employs a small passenger chassis fitted with very small diameter wheels with solid tires. These are driven by girls, who operate the vehicle only, the loading and unloading being done by men. These vehicles are very efficient in transporting from building to building, as well as in some of the larger departments.

Factories Greatly Enlarged

Nothing is more impressive to the visitor of Europe than the new factories. When contrasted with the factories that existed in 1912, you get an immediate conception of what the war has meant to France, England and Italy. You get a new realization of what is conveyed by the oft-used phrase "a war of mechanics." The mechanical devices before the war have to a very large extent been the products of the automobile and motor truck manufacturer.

Renault is a typical example in France of this. The factory has grown out of all pre-war proportions. It has grown beyond the conceptions of the Renault organization of 2 years ago. None of the manufacturers in 1914 or 1915 had any conception of what 1918 would accomplish. As a result many of the factories are not as organized and symetrically laid out as might be expected. Renault, for example, increasing more than five-fold, has spread all over the lot, so to speak, and while the organization in the different buildings is generally good, there is naturally a manufacturing loss because of the number of different buildings and the location of them. Because of the variety of manufacture it was also impossible to build up under war pressure any broad scheme of factory layout. Because of this there will be much rearrangement taking place during the present year.

(To Be Continued)

S. A. E. Discusses Truck Subjects

1—Pneumatic Tires for Trucks

B. B. Bachman

2—Summary of Truck Engineering

Cornelius T. Myers

3—Keeping 40,000 Army Trucks Running

G. E. Randles

NEW YORK, Feb. 11.—Three papers covering truck subjects were presented last night at a meeting held at the Automobile Club of America, under the auspices of the Metropolitan Section, Society of Automotive Engineers. Cornelius T. Myers, consulting engineer, Avenel, N. J., presented a general summary of truck engineering development; B. B. Bachman gave a paper on pneumatic tires on trucks, and G. E. Randles, until recently director, Division of Maintenance, Motor Transport Corps, told of some of the problems in keeping 40,000 army motor trucks in operation.

Mr. Bachman reached some important conclusions in the field of the pneumatic tire for the motor truck. He gave it as his opinion that for vehicles up to 1500 lb. capacity pneumatic tires only are proper. From 2000 to 3000 lb. inclusive there is a strongly marked tendency toward pneumatics which it is believed will develop continuously. On the 2 and 2½-ton trucks they are just making an appearance, and are still in the experimental stage, while on the larger size there is practically no evidence apparent that the heavy pneumatics will be used.

The reasons given for these conclusions are taken up definitely in Mr. Bachman's paper, which is digested herewith. The subject is one of intense importance because of the growing use of motor trucks for long-distance carrying. Furthermore, as the use of pneumatic tires is a factor in the decrease of gasoline consumption, and also lessens the depreciation of roads, it is a matter of extreme importance at the present time, when both the fuel and road prolems are being given as close as possible study both independently and as co-related matters.

Room for Detail Improvement

Cornelius T. Myers covered a broad field in his paper, this being in many ways a result of his varied experiences, including that in the design of the Class B truck. Mr. Myers stated frequently that while we have fairly satisfactory development along many lines of truck construction there is a great necessity for detail improvement. Digesting his remarks, they covered the following points:

One of the phases of truck design which has not been given all the attention which it deserves is that of accessibility. In a very large number of instances the question of cost of construction vs. accessibility comes up, and the decision is not always in favor of the accessible method of construction. Mr. Myers made a plea for simplicity, stating that this not only resulted in fewer parts but also in more accessibility. He mentioned a certain concern in this city which is a large buyer of motor trucks which makes a practice of removing from the trucks several parts which in their opinion are superfluous and selling them to other users of the same make of truck.

Comfort for the driver is a highly essential matter in truck design, particularly when it is remembered that trucks are operated for much longer spaces of time than passenger cars; and furthermore, they must be out in all sorts of inclement weather. The driver is compelled, during his attention to his duties, to exert a tremendous amount of nervous energy, and for the general safety of the other occupants of the streets, and for the general good of the apparatus handled, as much should be done as possible to relieve the driver of mental strains.

Mr. Myers touched for a moment on the gain in speed possible with the use of giant pneumatics. The further use of these, he predicted, would result in more attention on the part of designers to the layout of the brake and steering. The speed proposition, however, is a matter of extreme importance when it is realized that for real efficiency it is necessary to keep the trucks moving. The faster the average speed the better paying is the truck. The average speed in taking into consideration the entire period over which the trucks operate is not only governed by the time it spends on the road but also what is lost by waiting or by overhauling.

Transportation Cost Should Come First

According to the author, the cost of transportation by truck should be put first and the cost of the truck next. That is, in laying out a truck transportation system the first cost of the truck should be figured not as standing alone but as being only part of the entire problem of determining exactly what truck transportation is costing the owner of the vehicle or fleet of vehicles. This is a broad gaged method of calculating the value of the truck or fleet of trucks to the owner, but one which is forgotten frequently by the truck purchaser.

In the design of a truck it is very often possible to combine units so that there are parts with double and triple functions. This results in a reduction in weight and increase in simplicity, and often because of the combination of functions a designer is enabled to allow a greater factor of safety and still have finally a lighter part.

In taking up details of construction, Mr. Myers pointed out several directions in which future improvements in truck construction are necessary. Better cooling systems are required, and it is particularly necessary to look into the design of radiators, to see if they cannot be lightened, as a great amount of weight over the front axle results in making the truck hard to steer. Spring suspensions can also be improved. The use of longer springs is increasing, but lubrication of the spring eyes is often faulty; in fact, he stated many spring breakages are directly traceable to the neglect of oiling the spring eyes. This causes the bearing at this point to seize, giving an action which overstresses the main leaf, allowing it to break.

Hearty approval is being given the use of oil fittings instead of grease, but one of the criticisms offered on this method of lubrication is that the oil fittings, in many cases, admit dirt and water. They are also very frequently of

such construction that they are apt to be knocked off and broken.

The magazine system of oiling the spring brackets, as utilized on the Class B truck, was explained in detail, and was shown to have worked out generally satisfactory except at one minor point, which is readily corrected. This is in the use of too loose a fit of the wick, in the case of the front springs. When this wick is too loose the oil rapidly siphons from the reservoir, thus emptying it, and necessitates the renewal of the wick, giving it a tighter fit.

As an example of the real influence of this method of oil lubrication on ease of spring suspension Mr. Myers mentioned a truck utilized in transporting berries on the Pacific Coast. He stated that in this work the trucks using the magazine oiled suspension were allowed an increased rate per crate owing to the easier suspension, which prevented injury to the delicate berries.

There are other points on the chassis which should be lubricated in some way more closely, like the spring brackets, just described. These are such inaccessible points as the brake rocker mechanism, and so forth, which are seldom touched, but which would probably be lubricated more consistently were it necessary to renew the supply in the reservoir but once in 2 or 3 months.

Axles are generally good, according to Mr. Myers, but it would be well to look further into the matter of unsprung weight and see if more cannot be done in this respect. The paper concluded by pointing out that the time has now come to build for future development and permanent business. Mr. Myers cited the appeal for higher standards of quality voiced by an article by H. M. Swetland, president of the Class Journal Company, in an article in AUTOMOTIVE INDUSTRIES for January 23.

Keeping Army Trucks in Operation

Systematized maintenance in the army had reached a high state of development when the armistice was signed. This is made evident by the report given by Mr. Randles on keeping 40,000 army motor trucks in operation.

Obviously, keeping in repair 40,000 trucks, motorcycles, and any other motor equipment coming under the care of the Motor Transport Corps meant processing, standardization and quantity-production methods. The maintenance division of the corps adopted methods based on the experience of the foremost manufacturers of motor vehicles in the country. Motor experts were called on to give the results of their experience, and their advice adapted to that of army men who had observed motor transportation on the Mexican border. These men brought together the best practices, eliminated the faulty, and kept those that had stood the test. They picked the best standards and established definite limits to work to. Accuracy was adapted to production. A system of thorough inspection of every part was established and the final test made practically error-proof.

In the standardized repairshops the vehicle receives a complete rebuilding in all of its parts, including engine, transmission, body, upholstery, electrical apparatus, etc., and when finished, barring hidden flaws in some of the parts not replaced, it has at least the original capacity, and in many cases is capable of greater length of service than when new. The work, from the time the vehicle reaches the dead line until it passes through its process of rebuilding, is on the progressive system. In fact, in this plan modern manufacturing methods are applied to repair work, which results in low cost, large production, and the use of unskilled or specialized labor.

The schedule and routing department from the time a truck or other motor vehicle arrives in the storage yard, or "dead line" of a mechanical repairshop, keeps a record of it. As soon as it is assigned a position in the storage yard the arrival is noted in the production and schedule office and a record is made of the truck make, manufacturer's number, job number, and United States truck number. It is then surveyed and inspected by the survey board, which reports on the condition of the truck and recommends either rebuilding or salvage.

This report, approved by the shop commander, is the basis of the repair instructions. An identification memorandum is issued by the production department to the battery repairshop, advising that the truck is on the "dead line."

This shop removes the battery from the trucks, puts it in A-1 shape, holding it until the overhauled truck is ready for test. When the chassis-bay foreman has space for another job the production department assigns the truck to a vacant stall in the chassis bay. All these stalls are numbered consecutively, and the truck is tagged with its stall number.

A memorandum is then sent to all the departments, bearing truck made, manufacturer's number, job number, United States truck number and stall number. Every department then has full data on any unit which may come to it, identified only by its staff number.

As the various units are removed they are tagged with the stall number and placed on trailers in the center aisle of the bay. These trailers are picked up by tractors and taken to the distributing point in the main aisle, whence they are moved to their respective shops to be overhauled. The engine, transmission and driveshaft, rear axle, brake, front axle and steering column all go into the general overhaul and machine shop. Each part is tagged with a metal tag bearing the stall number. Parts coming from repair are inspected before being sent back to the stall. New parts are also inspected. After the engine, transmission and other units are put together in the sub-assembly and final assembly departments they are returned by trailer and tractor to the stall from which they originally came. The truck is put together again by the same gang that tore it down.

Organization of Division of Maintenance

The final test is thorough and intended to check repairs. It is given by a separate department and a group of men who had nothing to do with the actual repairing. The tested and approved truck goes back into service as good as new, and probably in better condition than 95 per cent of the trucks repaired in civil life.

The maintenance division of the Motor Transport Corps is organized for overhauling and rebuilding motor equipment in the United States and to supply parts, tools and personnel of mechanical repair units for overseas service. Maintenance repairs in the field are made by service park units which are mobile, or semi-mobile, and consist of 35 men with equipment. These units can be taken into the field, close behind the lines, where repairs can be made as the emergency demands.

Mechanical repairshops for overhauling in the United States are standard in size, eqquipment and personnel. Each is housed in a building of thoroughly modern, fireproof, concrete construction, so planned that considerable extensions can be made without disturbing the original floor arrangement. The original unit is 497 feet square, providing space to carry on 120 truck overhaul jobs at one time.

Within this enclosure is assembled equipment for completely rebuilding any style of motor vehicle. The men are so organized in all departments that the work is understudied all the way through; they are equipped with hand tool kits which are just as much a part of their equipment as a rifle is for an infantryman. The tool kits have been standardized for various classes of work and give each man the necessary tools for the job to which he is assigned and more or less confine his activities so that he will work as instructed.

Pneumatic Tires on Trucks

The most pertinent questions that arise in connection with determining the feasibility of the use of pneumatic tires are probably these:

(1) On what sizes of trucks can they be used?
(2) In what class of service?
(3) On what kinds of roads?
(4) What advantages are obtained?
(5) What disadvantages become evident?
(6) Will it be necessary to radically modify truck construction to use pneumatic tires most economically?

An analysis of data contained in AUTOMOTIVE INDUSTRIES, Jan. 16, 1919, shows that on trucks ranging from 1000 lb. to 5 tons' capacity the maker's equipment for tires is as given in the accompanying table:

Capacity Tons	No. of Models	Solid Only	Pneumatic Only	Optional
½	14	0	13	1
¾	18	3	14	1
1	64	41	8	15
1¼ to 1½	71	59	1	11
2 to 2½	128	118	2	8
3 to 3½	81	80	0	1
5	63	62	0	0

It must, of course, be recognized that this does not give an indication of the cars which have had their equipment changed by the owner after purchase, and probably does not give an indication of the cases where pneumatic equipment has been furnished at the customer's request. Conversely, if a sufficiently large demand had arisen, the manufacturer would undoubtedly have recognized the fact by listing as optional equipment.

The Field of the Pneumatic Tire

Viewing the figures with these facts in mind, it would seem to be safe to say that for vehicles up to 1500-lb. capacity pneumatic tires only are proper. From 2000 to 3000 lb. inclusive there is a strongly marked tendency toward pneumatics, and on 2- to 2½-ton trucks they are just making an appearance, while on the larger sizes there is practically no evidence apparent from this source. We have all seen large trucks of 3, 4 and possbly 5 tons' capacity with pneumatic equipment, and the fact that makers are not listing them would indicate that the proposition is still in the experimental stage.

The advantages claimed for the pneumatic tire are numerous. Some of these claims are so obviously correct as to need practically no discussion; others are open to considerable question. Also, as with every matter of this sort, the answer is not to be obtained from any one factor in the problem, but after the bearing which each factor has upon all the others has been given consideration.

The claims of advantage which are made may be listed as follows:

(1) Reduction in mechanical repairs.
(2) Increase in permissible speed.
(3) Decrease in gasoline consumption.
(4) Decrease in oil consumption.
(5) Less fatigue for men.
(6) Lessened depreciation of roads.
(7) Greater tractive ability.

The reduction of mechanical troubles can be accepted as a fact almost without comment. One point to be considered, however, is that while the net trouble is reduced, it is apt to change in character. With solid tire equipment, due to the shocks on the portions of the chassis which are not spring borne, the greater amount of difficulty is caused by the wear and looseness developed by this action. The small amount of resiliency in the wheels causes sharp blows to rack and twist the chassis structure, whereas the pneumatic tire absorbs a larger proportion of these shocks, and thus reinforces the spring action in relieving the chassis. There is, however, a reverse side to this, caused by the greater speeds which in spite of the generally larger sized wheels result in higher engine speeds. This sets up mechanical vibrations, which in conjunction with other trouble engendered by high engine speeds, raises the proportion of trouble in this part of the mechanism. However, as stated before, the total amount of trouble is decreased, and this becomes more apparent when placed in proportion with the car mileage.

Runs to test fuel economy were made with different loads; in the case of the solid tire one run was made with a considerable overload, which was not duplicated on the pneumatic tires. The results obtained are tabulated below:

Test No.	Weight Empty Lb.	Load Lb.	Total Weight Lb.	Ton Miles Per Gal.	Total Time in High Gear Per Cent
1*	4,500	525	5,025	30.33	89.1
2*	4,500	2,350	6,850	32.45	77.7
3*	4,500	4,175	8,675	36.35	62.7
4*	4,500	5,900	10.400	42.00	57.1
5†	4,500	680	5.180	28.20	81.3
6†	......4.500	2,000	6,500	32.10	74.6
7†	......4.500	3,580	8.080	31.96	62.1
8‡	4,500	550	5.050	24.40	88.2
9‡	4,500	3,480	7,980	27.40	63.0

*Solid tires.
†Pneumatic tires and the same axle reduction.
‡Pneumatic tires and a changed axle reduction to compensate for the greater wheel size.

The tests were made as carefully as possible and are, to say the least, disconcerting in the results shown. It is possible and, in fact, very probable, that these results are due to the form of the tires, which were not of the conventional cross-section and were designed to operate at considerably lower inflation pressures than normal.

General observations lead me to believe that the performance with regard to gasoline consumption will vary according to the road conditions. On very good roads there will be little or no difference, while on bumpy roads the pneumatic tire will show up the better.

Objections to Pneumatic Tires

The objections to pneumatic tires are not so numerous, but need careful consideration lest we be carried away with the idea that their use offers a solution for all troubles with no problems of their own needing attention. These objections are in my opinion:

(1) High initial cost compared with solid tires.
(2) The need of carrying emergency equipment.
(3) The difficulty attendant on making road changes due to weight and high inflation pressures required.
(4) Reduction of the high gear ability and limitation of the total ability due to larger diameter of wheels.
(5) Limitations imposed on the size of brakes due to the small size of wheels.

A material increase in tire mileage must be obtained to bring the cost per mile down to within a reasonable comparison with solid tires. Fortunately, this seems perfectly possible, at least up to 2 tons' capacity. On the group of cars which has been used before in this article for illustration, the grand average of reported mileage to date is 14,000 miles. One make of tire has averaged 19,000 miles, and of all the tires none has given less than 6000 or 7000 miles.

The weights are roughly as follows for an inflated tire and demountable rim: 38 by 7-in., 152 lb.; 40 by 8-in., 213 lb.; 44 by 10-in., 400 lb. These figures represent weights that require quite a bit of handling.

Inflation Pressures Recommended

Inflation pressures recommended are: 5-in. section, 80 lb.; 6-in., 90 lb.; 7-in., 100 lb.; 8-in., 110 lb.; 9-in., 120 lb.; 10-in., 130 lb., and 12-in., 140 lb. It is impracticable to consider hand pumping for any but the 5-in. size, and a mechanical pump to do the job is quite a piece of apparatus, and to be installed correctly adds another considerable item of expense which must be taken into consideration.

By referring to the table, it will be seen that the driving wheel diameters are increased as follows:

Capacity, Tons	Old Diameter In.	New Diameter In.	Increase in Diameter Per Cent
1..............	34	35	3
1¼ to 1½......	34	36	6
2 to 2½......	36	40	11
3 to 3½......	36	44	22½
5..............	36	44	22½

On the smaller sizes the change is not so great and will probably work no material hardship except in cases where the brake equipment is on the transmission. With the larger sizes the difference is so great as to make it extremely doubtful whether there is sufficient flexibility in any well-designed truck to permit successful application.

Capacity, Tons	Solid Front, In.	Solid Rear, In.	Pneumatic Front, In.	Pneumatic Rear, In.	Increased Cost Pneumatic Over Solid, Per Cent	Increased Cost Pneumatic Over Solid, Including Extra Tires, Per Cent
1	34×3½	34×4	35×5	35×5	80	125
1¼ to 1½	34×3½	34×5	35×5	36×6	93	184
1¼ to 1½	36×3½	36×5	35×5	36×6	77	165
2 to 2½	36×4	36×7	36×6	40×8	110	216
3 to 3½	36×5	36×5 dual	36×6	44×10	87	180
5	36×6	36×6 dual	38×7	44×10	60	140

N.A.C.C. Truck Convention A Success

Few Surplus War Trucks in America—Prospects Not Bright for Exports to Europe—Truck Registration by Speed and Weight—More Standardization Needed—Standard Warranty Needs Revising

NEW YORK, Feb. 11—Representatives of over seventy-five motor truck makers attended the truck convention held to-day by the National Automobile Chamber of Commerce, the convention being one of the best held in some time by the chamber. Subjects relating to increased use of motor trucks and improved systems of handling them were discussed. The convention covered a wide range of subjects and turned the meeting into a kind of house-cleaning day on many matters relating to trucks.

A new system of registering motor trucks on a basis of speed and weight was recommended by George H. Graham. A similar system was recommended for all horse vehicles.

Col. Fred Glover intimated that there will be very few surplus war trucks and that most of our war trucks in Europe will be disposed of on the other side of the Atlantic.

The complete elimination of the truck warranty by manufacturers and the sale of trucks on their merits and reputation was recommended by E. J. Herbig.

David Beecroft in reviewing possiblities of foreign trade in trucks showed that prospects are not bright for such trade at present due to the large surplus of war trucks owned by our Allies.

David C. Fenner asked for standardization of more truck parts and emphasized the necessity of such in throttle and spark levers as well as with gearshift and brake levers.

E. J. Mehren favored a federal system of highways to supplement state systems and the necessity of a great educational campaign on highway improvement and the better use of highways.

James I. Blakslee advocated a better national system of transportation by closer correlation of the post office, the highways and the motor truck.

A committee of truck men was appointed to discuss with a committee of the tire makers what truck tire sizes should be eliminated.

Few War Trucks for Sale

Col. Fred Glover of the Quartermaster's Department U. S. Army, in discussing the probability of disposing of any surplus war trucks which might be on hand after the determination of the size of the U. S. A. standing army in this country, was of the opinion that none of the U. S. A. war trucks now abroad would ever be returned to this country but would be sold abroad, together with the large stock of spares for such vehicles already shipped overseas.

In answer to a question as to whether the public auction of 325 trucks owned by the United States Spruce Production Corps in Portland, Ore., on Feb. 15 is an indication of the government's policy regarding the disposition of surplus trucks, he stated that the War Department had no jurisdiction over the trucks being auctioned off in Portland. Those vehicles were under the direct supervision of the Spruce Corps and not of the War Department.

He expressed it as his opinion that the various government departments would consume a large number of the motor trucks now on hand. No definite statement as to the possible number of such surplus trucks can be made at this time on account of the impossibility of knowing the needs of our army of occupation abroad and of our standing army at home.

There are fewer than 100 motor trucks owned by foreign governments now in this country which might be auctioned off. It is the intention of the government to cause the least possible disarrangement of the truck industry, and that all of the military trucks would be consumed by the various governmental departments if these had sufficient work for them to do.

There are enough spare parts on hand for these vehicles to prevent breaking up any second hand trucks to repair others of the same make and capacity.

S. M. Williams, president of the Highways Industries Association, brought out the fact that the Post Office bill which passed the Senate last week provides that any surplus military trucks be turned over to the various states for road building work and that the state governments pay for these vehicles in the same ratio as they share in the construction of federal aid highways. A large number of truck makers had objected to this plan on the ground that such disposition of surplus war trucks would cut off a possible market for new trucks. Colonel Glover stated that the motor truck industry could not expect to get back to a peace basis without some readjustment to make up for the large number of military trucks sold during the war.

A National Highway System

That a successful system of national highways must be built, laid out and maintained exclusively by federal funds; that the maintenance and control of such a system of highways must be vested in a Highway Commission and not in an obscure office of a governmental department, and that a great educational campaign must be conducted to convince 100,000,000 people of the new development in highway transportation were the three cardinal topics discussed by Edward J. Mehren, representative of the Highways Industries Association.

The various states cannot be expected to spend their highway appropriations except for the greatest benefit of those states. The national system of highways would have to be built with the view to serving the country as a whole irrespective of the economic advantages of such a route to the particular states which it crossed. He emphasized the fact that the national system should be carried on in addition to the federal aid road construction and that these latter roads would act as feeders to the main truck line. He further urged the increased use of federal aid funds as an incentive to the establishment of competent highway departments or commissions in those states which are now backward in road development.

A Federal Highway Commission, according to Mr. Mehren, is the only logical manner of supervising the building of a national system of roadways, since the various states could not be expected to maintain such a road to the same degree as would be the case if the government had the work in charge.

Highway transportation has developed more in the last 10

years than the railroads did from 1830 to 1880, a period of 50 years. The great majority of the present voters were brought up under conditions which existed before the beginning of this new era of highway transportation by motor vehicles and must be educated along new lines before the realization of the great road building program can be accomplished.

Register by Speed and Weight

A new method of state registration of motor trucks based on speed and weight was advocated by George H. Graham, chairman of the Motor Truck Committee of the N. A. C. C. and presiding officer at the convention. There should be some fundamental systems of registration and the two cardinal principles in such a system are speed and weight. The suggested method of determining trucks license fees based on speed and weight would eliminate the present discrepancies which vary from $5 to $125 for a truck of the same speed and capacity in various states. Connecticut has the $125 fee for a 5-ton truck and Massachusetts has $25 for a similar truck. Other states further west have a $5 fee for the same capacity vehicle. No action of the convention was taken on the suggestion.

The proposed rates for pneumatic tired trucks was 25 cents per horsepower plus 25 cents per 100 lb. of the gross weight of the truck and load.

For trucks with two or more solid tires the corresponding rates would be 25 and 35 cents.

For trucks with iron or steel tires the rates would be 25 and 50 cents.

Horse vehicles should pay their share of taxation for road maintenance by a tax of $3 for wagons under 1000 lb. capacity, and for wagons over 1000 lb. $3 plus 50 cents additional for every 100 lb. above the 1000 lb. limit.

Small Export Trade

The possibility of truck export trade with Europe, analyzed by David Beecroft, Directing Editor of AUTOMOTIVE INDUSTRIES, who has recently returned from a three-month investigation of conditions in Europe, showed that prospects are not specially bright at present, due to the large war production of England, Italy and France and the number of new and used war trucks that will be turned back into industry as soon as peace is finally settled.

The British manufacturers are much perplexed over this situation. To-day there is no such thing as exporting trucks to Great Britain because the order of total restriction against imports is in force and is likely to remain in force for some time to come.

There are in England 20,000 new war trucks that can be turned into the channels of industry. In addition there are available nearly 50,000 used war trucks, most of which will be repaired or rebuilt before being put into industry. Added to this are 10,000 ambulances not needed in the war work and 12,000 light delivery vehicles, which give a grand total of nearly 90,000 vehicles.

The truck production of Great Britain for 1919 has been estimated at 20,000 trucks of all capacities, so that in view of this figure the magnitude of the war trucks that can be returned to industry becomes apparent.

The production of British truck companies varies from the largest factory with a capacity of 125 trucks per week to others having a capacity of but a few. There are, among the leading makers, two with a capacity of 25 per week each, and others with capacities of 18, seven, six, five and four per week.

Italy had a very large production of trucks during the war, Fiat alone selling upwards of 50,000 to the Allies. Fiat's maximum production reached 170 per day and for months its production approached 75 per day. In Italy such other firms as Spa and Lancia have been building trucks in quantities during the war. France, England and America purchased large quantities of Fiat trucks.

Great Britain has passed a bill appropriating $130,000,000 for road improvement, which augurs well for an increased use of motor trucks. It will be impossible to expend this sum in a year, but it will be expended as rapidly as possible.

There has been a big increase in electric trucks in London during the war due to the scarcity of gasoline and the cheapness of electric current. Before the war there were 250 electrics in London and now there are 2000. The manufacture of electric trucks is being started in England by one firm that aims at an early capacity of 60 vehicles per month.

The use of steam trucks has increased very largely in England, partly due to the adoption of solid rubber tires on these in 1915. Now the steam trucks burning coal travel as rapidly through the streets of London as gasoline types. In the war zone are hundreds of steam trucks used in road building and salvaging. The use of coke as a truck fuel has been under development of late. The fuel cost for steam truck approximates 50 per cent of the cost of gasoline types.

Urge Elimination of Truck Warranty

Entire elimination of the standard warranty covering material and workmanship in trucks was recommended by E. J. Herbig, sales manager of the Service Motor Truck Co. The warranty was necessary in the early days of the industry but not to-day with the developed trucks. To-day the standard warranty is really an indication that something is going to happen to the truck.

This view was concurred in by David S. Ludlum, president of the Autocar Co. It is not expected that any such radical action will be taken, but Mr. Herbig recommended an immediate revision of the warranty in order to make it more considerate of the owner and yet not work any sacrifice on the maker.

The warranty should cover tires and truck equipment. The warranty should be rewritten to cover trucks specifically, and since the governor is such a factor in truck operation it should be written into the warranty that tampering with the governor and operating the truck without the governor cancels the warranty.

In handling spare parts Mr. Herbig had some suggestions to offer the truck maker, such as: The dealer should have the opportunity of returning obsolete parts within one year and should be paid the price for them that he originally paid the factory. The dealer should be required to carry a stock of spares sufficient to take care of the trucks in the territory. In returning defective parts the dealer should tag them showing the name of the truck owner, serial number of the truck and date of the fracture. Dealers should be given discounts on spares in accordance as they carry adequate supplies for the trucks in use. There should be a better standardization of the names of truck parts so as to avoid confusion that follows where dealers use different names for the same parts.

In connection with the standard service policy for trucks it was recommended that the dealer be impressed with the evil of idle trucks due to any cause. An idle truck is the poorest kind of advertisement.

More Standardization Needed

That truck manufacturers have never given sufficient consideration to standardizing the position and manipulation of spark, throttle, gearshift and emergency brake levers is the opinion of David C. Fenner of the International Motor Co.

A standard gate or location of the gearshift positions in relation to the driver's seat is highly important. If the S. A. E. standards which already apply to these features are not commercial, manufacturers should apply for a revision. If, on the other hand, these are among the details of motor truck design which are quite likely to be changed by further development, it would not seem wise to attempt their standardization at present.

The types of chassis standardized for army work during the war emergency contain details of design selected by the engineers, who volunteered for this work, as representing the average practice of the times with the extraordinary requirements of army service kept constantly in mind.

The fact that these engineers considered it necessary to develop special types for army work does not necessarily indicate that these types will prove practical and economical for average commercial service, and as this is the problem of the immediate future, it is the basis on which we must consider the advisability of further standardization.

Engineering Refinement Evident at Truck Show

Better Driver Protection—Oil Chassis Lubrication—Pneumatics for Lighter Types Among Developments

NEW YORK, Feb. 10—The motor truck show, which opened here to-day at Madison Square Garden and the 69th Regiment Armory, has 144 vehicles on the floor, some of which are new models and 22 of which were not shown at Chicago. The trucks show a refinement of detail which parallels what has been found in the passenger car industry. There is little or nothing of a radical nature, but minor refinements are plentiful, particularly as regards chassis lubrication and in the better protection of the driver.

Tractors Shown for First Time

Tractors were on the floor for the first time at a New York show. Four makes were represented, Fordson, Maxim, National and Emerson-Brantingham. These attracted such a great amount of interest that doubtless the farm tractor is going to be present at future truck exhibitions. There was no attempt made to segregate the tractors and make a tractor section of the exhibit, but these were put along with the motor trucks.

In a great number of exhibits, special bodies were shown, which made it apparent that one of the effects of the war and the experiences in the Motor Transport and other corps is to produce bodies which are more carefully designed for the specific task they have to perform. The bodies are of all styles, even including the public service type, such as a pay-as-you-enter bus, fire-engine, ambulances, hearses, and so forth, and there are also a number of new designs of convertible side stake and side panel types. One of these has interior shelving for assisting in efficiently handling small package work.

Five Makes of Converters

There are five makes of converters for turning passenger cars into trucks, and three makes of trailers. A number of the accessory makers retained their booths from the passenger car show, but altered materially the nature of the product contained in them so as to make them directly applicable to trucks.

There are a few new models on the floor, such as the Fulton 3 to 4-ton tractor and trailer, a new 1-ton Columbia, a new 5-ton Acme and a 2-ton Shaw. The new 3-ton Rowe is one of the up-to-date higher speed types, being capable of running at 30 m.p.h., and is mounted on pneumatic tires. It is equipped with a Herschell-Spillman eight-cylinder engine, and the rear axle is worm driven. The newer makes are all assembled types and a number of them use the Continental truck motor, this being evidenced by its employment in the Columbia, Acme, Shaw and other types which have not been previously exhibited.

One could not fail to be impressed with the fact that the use of pneumatic tires is increasing rapidly in the lighter capacity vehicles. Up to 2½ tons this is a matter of common usage, and it is even predicted by some of those exhibiting that the utilization of pneumatics for even heavier capacities is going to come in on a larger scale than was expected. This has come about very largely through the demand for higher speed in connection with long haul work. It is necessary to maintain a good average rate if long distance truck haulage is to be made a paying proposition, and the use of pneumatics is counted on to make high speeds possible without undue strain on the vehicle. This is an important consideration at the present time, when maintenance of roads and conservation of fuel are in everyone's mind.

Oil lubrication has supplanted grease on a great many of the trucks, the new Columbia, for instance, having entirely gone over to oil for all the chassis bearings. It is a noticeable feature that many of the manufacturers of trucks, in the same way as those who make passenger cars, seem to believe that it is necessary to make the oil cup as large as the grease cup which it replaces.

This is not only untrue, but it is positively harmful, because the larger oilers more readily admit dirt and water than the smaller type. It is always necessary to fill oil cups anyway, as they are not able, as a rule, to retain the lubricant, nor to act as a reservoir. Therefore, unless some reservoir system is used at the bearing, a few drops injected into a small oil opening is just as satisfactory as an over-supply in a cup which is too large.

Heavy Radiators the Rule

It is noticeable that many of our trucks are very heavily loaded over the front axle. The cause of this is a heavier radiator than perhaps could be constructed if particular attention were paid to the lightness of this unit. None of the radiators on the trucks seem to be designed on the basis of lightness, but it is very well possible that a reduction in weight at this particular point might make steering easier and lighten the stresses on the steering parts.

Better cushions, deeper springs under the seats, more enclosed cab protection and improved control layout are among the features which are found in the new trucks. This attention to the comfort of the driver is recognized as contributing materially to the possibility of securing better performance from the truck. In other words, a tired driver is not a good driver. He cannot take care of the vehicle in his charge if he is weary, due to the handling of badly laid out controls and uncomfortable from his exposure to the elements.

—

ACCORDING to the Government reports, the exports of tungsten ore from the Federated Malay States for the year 1917 amounted to 761.31 long tons, as against 515.47 tons in 1916. In 1913 the production of tungsten ore in these States was only 225.06 tons, so that the output has more than trebled since the outbreak of the war. The export figures for 1917 do not accurately represent the production of tungsten ore, some of the ore included in the above figures having been sent to the Federated Malay States for treatment and re-exported.

FUEL

HOW CAN CRUDE OUTPUT BE INCREASED? HOW CAN WE INCREASE THE GASOLINE YIELD?

Greater Co-operation Between Refiner and Automotive Engineer Needed—Mexican Oil May Not Be as Plentiful or as Useful as Generally Thought—Three Possible Substitute Fuels Are Benzol, Alcohol and Shale Distillate

Improved Design of Automotive Apparatus Can Have Important Bearing on Future Consumption of Fuel—Crankcase Dilution Serious

ONE of the most vital phases of the winter meeting of the Society of Automotive Engineers, held in New York, was the discussion of the fuel situation. The lesson derived from the meeting is that the time has arrived for co-operation between the refining and automotive manufacturing industries. We are now drawing on our reserve stock of crude petroleum and the curve of consumption has crossed the curve of production. With this condition, predictions are freely made by petroleum experts that gasoline prices are due for a sharp rise unless present conditions, either as regards fuel or consumption, are changed.

From the papers presented by Joseph E. Pogue of the United States Fuel Administration, who gave an interpretation of the engine-fuel situation, and Dr. E. W. Dean of the Bureau of Mines, who spoke on sidelights on oil refinery practice, it was quite evident that new petroleum discoveries and new distillation methods, while augmenting our supply, are not keeping pace with the increase in demand due to the more extended use of automotive apparatus.

It was pointed out by the authors of these papers that the matter is not solely one for the petroleum expert to solve. The low thermal efficiency of the internal combustion engine is one of the greatest causes for the excessive use of fuel. Automobile engines operating under very small throttle openings, as a rule, are not more than 8 to 10 per cent thermally efficient. In other words, from 8 to 10 cents' worth of propulsion is secured for a dollar's worth of fuel. If the thermal efficiency could be materially raised the available supply of fuel would go a long way further.

At the present time we are getting about 20 per cent gasoline from crude. This factor, like the supply of crude petroleum, is a variable figure and is directly dependent upon the sort of crude and the methods used in distillation.

As yet, the cracking methods have only been of minor assistance, but scientists are optimistic regarding the possibility of further increasing the output by extending the cracking processes and making them available for cracking not only the more volatile of the fuel oils, but also in handling the kerosene content.

The papers presented on the Mexican field showed that while there is a considerable supply of fuel to be obtained from this source, the mythical tales of fabulous deposits of petroleum do not seem to have any real basis in fact. There are many difficulties in the way of using any great quantity of the Mexican crude for some time to come, and it is very probable, according to Mr. Pogue, that the Mexican supply may be very largely utilized in taking care of the needs of the merchant marine and navy of Great Britain and the United States.

Very little discussion took place on the fuel situation among the members of the Society. This was due to the length of the program, which precluded the possibility of any extensive discussion.

Regarding the substitute fuels it was pointed out that there are only three which at the present time have any importance at all. These are benzol, alcohol and shale oil distillate. Benzol can be sold at a competitive price with gasoline, but it cannot be produced in quantities sufficient to be a material factor in the situation. Alcohol and shale oil can-

not, under the present circumstances, be made to sell at the price now obtained for gasoline. For this reason there has been no great stimulant to the development of the two latter products, although much development work has been done.

In surveying the fuel situation one is impressed by the big factor in fuel conservation that improved design is going to become. The higher thermal efficiency secured in aircraft engines has shown that there are possibilities along this line which have never, so far as known, been reached in automobile or truck practice.

Now that the tractor field is about to open up on a very large scale and since the tractor is going to be a heavy consumer of fuel, due to the fact that it is operating under heavy load conditions at all times, the matter of engine design becomes of the highest importance.

The descending volatility is increasing crankcase dilution to a marked extent, making it necessary to frequently renew the lubricating oils, thus adding to the expense of operation. Co-operation between the engineer and the refiner is necessary to solve these problems.

An Interpretation of the Engine-Fuel Situation

By Joseph E. Pogue

U. S. Fuel Administration

THE principal factors in the engine-fuel situation are the demand for liquid fuel and the adaptability of the internal-combustion engine, on the one hand, and the supply of crude petroleum, the gasoline-producing capacity of this material, and the substitute fuels in sight, on the other. Out of the interplay of these factors will come developments, focussed in the price of engine fuel, that will determine the future of the automotive industry.[1]

The Demand for Motor Fuel

The demand for engine fuel has been increasing over the past few years at an imposing rate. The nature of this expansion is shown graphically in Fig. 1. The construction program of automotive manufacturers, moreover, affords no prospect of let-up in the pressure of fuel requirement; on the contrary, the injection into the situation of a notable development in the capacity for truck production introduces an element that bids fair to overshadow even the tremendous automobile demand, while the item of tractor manufacture looms ahead with a fuel significance scarcely second in importance. If these matters be projected into the future unabated, it is evident that the supply of engine fuel will need to be doubled every few years. The automotive industry is young and vigorous, and its continued expansion will place an unexampled burden upon the engine-fuel resources of the country.

Adaptability of Motor Type

The automotive engine has developed and become standardized in its main features on the basis of cheap and volatile gasoline. Its improvement has for the most part followed the direction of convenience and performance, with secondary consideration to fuel economy. This trend has been sustained to the present time by the existence of a highly stimulated oil production, providing gasoline capacity in excess of gasoline demand. So long as this condition obtained there was no need for the automotive industry to concern itself with considerations of fuel supply, but now, with the gasoline capacity of the country beginning to give indications of strain, while the gasoline demand is just fairly getting launched, the question arises whether the exigencies of the future will allow the engine type continued freedom of development in luxury directions, or will force adaptations to meet the exactions of the fuel situation.

Automotive apparatus is mechanically responsive to changing requirements, but its adaptation to new conditions is retarded by the time required to perfect mechanical developments and the counter advantage to be gained from quantity production and standardization, with their antagonism to change. So far-reaching and insistent, indeed, are the claims in favor of holding fast to established standards that departures can be made only at great cost and in response to powerful reasons. Anticipatory action becomes peculiarly difficult in the face of these circumstances. Recognizing the strength of the opposition to changes in engine-type and seeking to force the fuel supply into channels fitting the established standards, we may examine the fuel supply with a view to determining if present engine standards can be advantageously maintained, and, if not, along what lines changes are likely to be made.

Supply of Engine Fuel

The engine fuel in dominant use in the United States is gasoline, a mixture of volatile liquids won from crude pe-

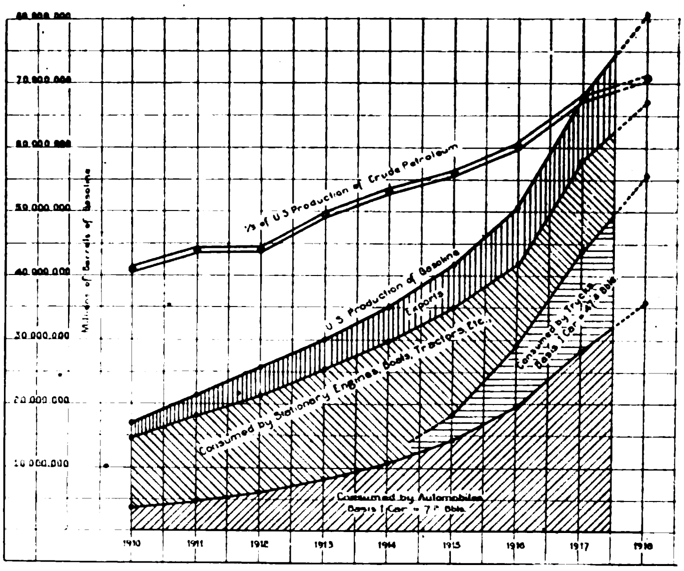

Fig. 1—The gasoline situation

This composite chart is drawn from data as follows: Crude production from U. S. Geological Survey; gasoline production from U. S. Fuel Administration and U. S. Bureau of Mines; automobile and truck consumption based on registration compiled by National Automobile Chamber of Commerce, and consumption factors worked out by War Industries Board (see manuscript report by M. J. Gillen on Regulation of Uses of Motor Cars, Gasoline, Rubber Tires and Rubber. Nov. 4, 1918). This chart is not exact in final detail, but is an interpretation of data approximately correct.

[1]The validity of the conclusions presented in this paper depends upon the correctness of the writer's diagnosis in respect to four basic points: The domestic supply of crude petroleum, the significance of Mexican petroleum, the significance of cracking, and the adaptability of the automotive apparatus. An independent check upon these points, which will serve to substantiate, modify or controvert the present argument, will be afforded by the other papers presented at the Fuel Session of the Annual Meeting of the Society, as well as by a study of the references given at the end of the paper.

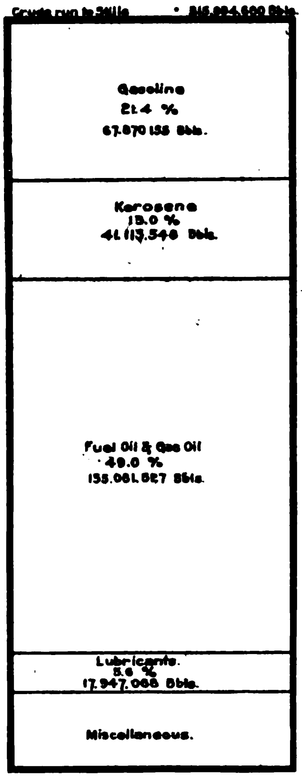

Fig. 2—Gasoline and its joint products. Data from U. S. Fuel Administration

troleum by a process of distillation.[2] Kerosene, fuel oil, lubricants and various by-products are produced at the same time, and bear an intimate relation to gasoline, both as to production and price. The relative output of these products in 1917 is shown in Fig. 2. The quantity of gasoline that the country is capable of producing depends upon the supply of crude petroleum and the gasoline capacity of this material.

Supply of Crude Petroleum

The supply of crude petroleum for years to come depends upon the unmined reserve and the rate at which it may be won. The reserve in the United States was inventoried by the U. S. Geological Survey in 1908, in 1915, and again in 1918, with results shown in Fig. 3. The significant aspects of the results are two: The small size of the reserve, approximating 6,000,000,000 bbl. in 1918 (our annual production is over one-third billion), and the fact that in the past ten years, in spite of an exceedingly aggressive campaign of oil exploration, the decrease in the reserve has exceeded the addition to the reserve through new discoveries. Those, therefore, who count upon new discoveries to materially affect the basic situation overlook the fact that for ten years already discoveries have been failing to do so.

At the same time the production of crude petroleum has been steadily mounting to its present enormous figure. This growth in output, shown in Fig. 3, has been sustained, not primarily by the discovery of new oil fields, but largely by the cumulative tapping of an increasing number of rich spots in inventoried territory. There is obviously a limit to an output supported by such a train of circumstances; there are strong engineering and economic reasons for believing that the output of crude petroleum in the United States is nearing its maximum and that the country will soon pass into a period of slowing and more costly production.

Gasoline Factor

The output of gasoline approximates[3] the supply of crude petroleum multiplied by its commercial gasoline factor,[4] which at the present time is about 20 per cent. This factor, like the supply of crude petroleum, is itself a variable figure depending upon the proportion of the crude supply subjected to refining, the natural gasoline content of this quantity, and the extent to which means are used for forcing the gasoline yield above the natural gasoline content. Obviously, so long as the natural gasoline is not fully extracted from the available crude, there is scant economic room for the development of roundabout, i.e., more intricate, more costly means for producing gasoline. This was the situation that prevailed in the United States until recently; this is why natural-gas gasoline, cracked gasoline and low-volatile gasoline are all recent commercial developments.

The proportion of the crude supply subjected to refining in respect to gasoline has been steadily increasing until the quantity so employed now approximates 95 per cent of the total.[5] Thus practically the whole output has now come to be requisitioned for gasoline production. This is to say that the readiest means for increasing the supply of gasoline, i.e., refining a progressively larger percentage of the crude produced, has been virtually forced to its limit; the "gasoline slack" within the crude production has been taken up. Thus the most potent circumstance that has thus far enabled the demand for gasoline to increase without a concomitant increase in price is no longer in existence (see Fig. 1). Further expansion in gasoline output will lie through a more difficult avenue than that of merely increasing refinery capacity.

Gasoline Content of Crude Varies Widely

While dependent primarily upon the quantity of crude refined, the output of gasoline is at the same time a function of the average composition of the various crudes that go to make up the total supply. Since crude petroleum varies in its natural-gasoline content[6] from about 2½ per cent in the case of heavy asphaltic oils to 25 per cent or so for light paraffine oils, it is evident that the gasoline supply will be strongly influenced according to the dominance of the one or other type of oil. As the high-gasoline crudes were the first to be exploited in this country, the unmined supply of petroleum has been selectively reduced in gasoline capacity,[7] so that the crude production of the future will show a lower natural-gasoline factor than the crude supply of the past. While this matter cannot be expressed quantitatively, in very rough terms it may be noted that the high-gasoline crudes are about half exhausted, while the low-gasoline crudes, originally of about equal magnitude, are only about a third used up. In other words, the country's gasoline capacity is being drawn upon more rapidly, and hence exhausted more quickly, than is indicated by the condition of the crude supply viewed alone. This tendency was of no immediate consequence so long as it could be compensated by merely refining a greater proportion of the output of crude; but now, since practically all of the domestic crude is used for gasoline extraction, a decline in gasoline content can be offset only by shoving crude production to a higher figure than would otherwise be necessary, or else through a still greater use of means for wresting an unnatural percentage of gasoline from the crude obtainable.

Means of Increasing Yield of Gasoline

The means for producing more gasoline than may be obtained by subjecting the total supply of crude to straight refining are: (1) increasing refinery efficiency, (2) blending high-volatile natural-gas gasoline with low-volatile refinery gasoline, (3) increasing the use of cracking in refinery practice, and (4) lowering the volatility of gasoline. All four means are increasingly in use. For the sake of brevity, the first two may be passed over with the comment that, while important, they have quantitative limitations which prevent them from broadly affecting the situation. This is not true of the second two, the limitations of which are of a different order.

Cracking is a process attachable to straight refining, by means of which low-priced distillates such as kerosene and fuel oil are re-run under more rigorous conditions and partly converted into gasoline. Obviously, cracked gasoline costs more to produce than natural gasoline, because of a greater consumption of capital, labor, material and fuel, and is commercially possible only after gasoline requirements have approached the quantity produceable by straight refining, and as long as there is a certain difference in market value between the raw materials used and the product turned out. The first condition has recently been attained, and there is already economic room for cracking; the second condition, if the prices of kerosene and fuel oil rise, can be maintained

[2]A small proportion of the supply is extracted from natural gas, but this does not largely affect the general situation.

[3]Because of the subordinate item of gasoline produced from natural gas, the relation is not an exact equality.

[4]The commercial gasoline factor is here used to represent the percentage of gasoline obtained from the crude consumed; the natural gasoline factor is the percentage of gasoline contained in the crude consumed. The first has increased until it has overtaken the second. (See Fig. 1.) The terms are used in a general sense.

[5]A much smaller proportion, of course, is subjected to complete refining with the production of the whole range of petroleum products.

[6]This term is used in a practical, rather than a strictly scientific, sense.

[7]The gasoline content of crude oil has been known to decrease even during the life of a given pool, which is a tendency in the same direction as that occasioned by selective extraction in respect to separate pools and fields.

only by a proportionate increase in the price of gasoline. The prospective growth in the use of the Diesel engine, especially for marine service, with its high fuel economy in the consumption of heavy petroleum distillates, may be expected to lessen the advantage that at the present moment accrues to cracking. Although the price of fuel oil is limited by the price of coal, the advantages of oil over coal for marine service are so marked that fuel oil can probably rise to $5 to $10 per bbl. before reaching its limit. Another no less potent factor bearing unfavorably upon the aid that the automotive industry may expect from cracking is the circumstance that the cost of cracking becomes greater as the percentage of gasoline demanded of a given quantity of raw material increases. This means, so to speak, that a little cracking may spread rather rapidly to all the crude refined, but much cracking will involve a step-up to a higher level of costs. In addition, the retarding influence that private control of patents will exert upon a widespread use of cracking processes should not be left out of account. Opposed to these unfavorable economic aspects of cracking, which offer relief only upon a basis of higher prices, is the matter of advance in cracking technology toward increased efficiency and lowered costs. Progress of this kind is undoubtedly in store, but advances under this head must work within the broad economic restrictions laid down above, and can scarcely be counted on to more than temper the price advances competent to maintain the requisite increase in cracking output. On the whole, then, there are reasons to believe that cracking, while of great importance at present, will under expanding use develop toxic properties, so to speak, which will limit its field of operations, if not ultimately remove it largely from the scene of action.

Lowering the Volatility

The fourth means for enlarging the output of gasoline independently of the production of crude is through lowering the volatility of the product. The less specialized the engine fuel in respect to volatility, the more can be produced from a given quantity of crude by the processes of refining in general use (see Fig. 2). By a change in character, the supply of "gasoline" can be enlarged, slowly or rapidly at will, without material refinery changes, until it is two to three times the present figure, even with no increase in the output of crude. Since the materials requisitioned in such a change are the basis of kerosene and fuel oil, which can be replaced almost entirely by coal and its products, the transition may be made without a basic disturbance of the country's economic fabric and without setting up counter forces tending to turn back the tide, as would be the case in an over-dependence upon cracking. The practical limit to this enlargement, however, is set by what the standardized automotive engine will accept in the way of fuel; which is to say that this avenue of advance is wholly in the hands of the automotive industry. The progress of gasoline in this direction has already gone about as far as practicable under existing standards of mechanical equipment; if the fuel current finds an unbreakable dam at this point, the whole pressure of advance will be thrown back into the channels already reviewed. Inasmuch, however, as the past few years have seen the volatility of gasoline steadily decreasing, in spite of laws and the desires of the automotive industry and the public to the contrary, while engine design has already been forced to respond to this circumstance with superficial adaptations, it is apparent that the channels of crude production, cracking, etc., have already demonstrated their incapacity unaided to accommodate the rising flood of gasoline demand. If these mainstays of the automotive industry are failing to meet the issue now, it is hazardous to count upon complete relief in this quarter when the pressure focussing there is rapidly increasing.

We have seen, so far as the petroleum situation in the United States is concerned, that an increasing supply of gasoline of present grade can be maintained into the future only through a growing use of cracking processes, involving material increases in the cost of production. But there are large oil deposits in Mexico which are believed by many to be capable of sustaining a North American supply of crude sufficient for all demands, even in the face of a slowing domestic output. What bearing does this factor have upon the engine fuel situation?

The Bearing of Mexico Upon the Situation

The oil-producing capacity of Mexico is certainly great, but the size of the underground reserve that will have to sustain production is largely an unknown quantity. The geological occurrence of Mexican petroleum is widely different from that of oil in the United States, and is of such a nature that the unmined supply cannot be readily inventoried. The output of Mexico to date has come largely from two wells of prodigious capacity, which have been held in check, but one of these wells is recently reported to have gone to salt water. There are, in addition, political difficulties in the way of the exploitation of Mexican petroleum, because of which the output will have to go in part to Great Britain, whose subjects hold extensive interests in the Mexican fields, and to other foreign countries. Mexican deposits are also involved in a large and growing fuel-oil demand in respect to the merchant marines and navies of Great Britain and the United States, which alone will tend to exhaust them rapidly.

Of even greater significance to the engine-fuel situation, however, than the quantity of crude that Mexico may be expected to contribute to the domestic supply, is the natural gasoline factor of this contribution. Unfortunately the natural gasoline content of Mexican petroleum is low, so that the more the domestic supply of crude is supplemented by imports from Mexico, the more the natural-gasoline factor of the entire crude supply is reduced, the more must cracking methods be called upon to sustain the production of gasoline. Thus, not only is the future of Mexican production a subject upon which adequate information is wanting, but, with the most optimistic assumption in that respect, the character of the supply is such as to be capable of sustaining an output of gasoline only upon a higher level of production costs* than now prevails. Thus Mexico, instead of offer-

*This may not be strictly true of gasoline produced in Mexico itself as a by-product of fuel oil for a period following the establishment of large "topping plants" and in event of sustained production in that country of crudes containing appreciable quantities of gasoline; but imported gasoline can scarcely be counted on in quantities large enough, or sufficiently soon, to materially affect the situation in the United States.

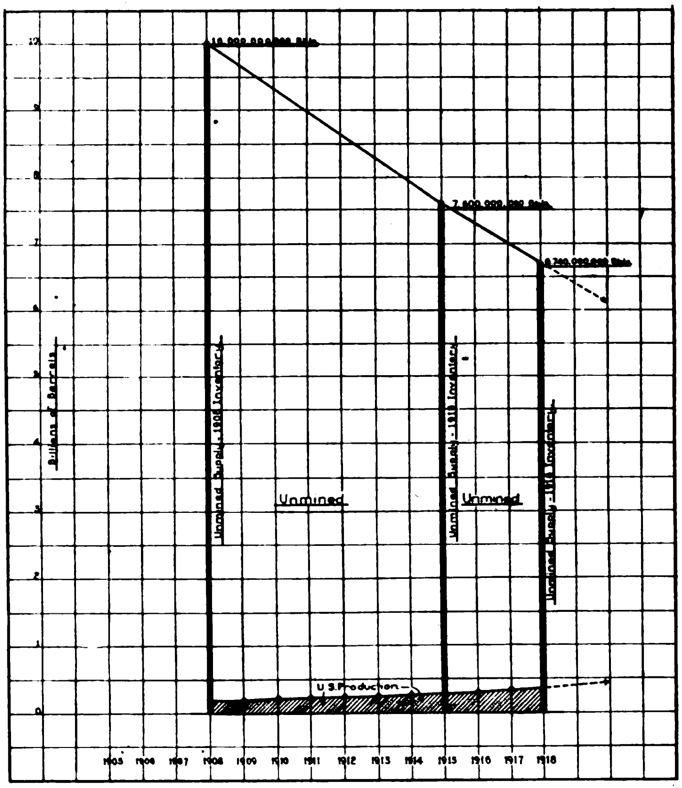

Fig. 3—The domestic crude petroleum situation. Data from U. S. Geological Survey

ing a solution to the engine-fuel problem, promises only to accentuate the issue, especially as the sudden leap in production that is impending from this source will lend a strong color of assurance to the situation.

The statements thus far made in respect to Mexico may, without substantial qualification, be extended to include the oil fields of Central America as well which will probably turn out to be heavy producers. As to South America, rather extensive explorations in most of the countries have failed to locate oil deposits of sufficient magnitude to bear materially upon the situation in the United States.

The Significance of Substitute Motor Fuels

The petroleum industry is so firmly established and produces such a range of products other than gasoline, that no engine fuel of non-petroleum origin need be counted on as capable of displacing gasoline.[9] Substitute fuels are to be regarded as supplementary resources, capable of affecting the situation broadly only as petroleum relinquishes the field through exhaustion.

There are three substitute engine fuels in sight—benzol, alcohol and shale-oil distillate. Benzol is now ready to compete with gasoline in a small way; alcohol and shale-oil distillate will be ready to compete only on a higher level of prices. As to resource capacity, benzol is a by-product of coal, and the quantity produced is dependent upon the coal subjected to by-product recovery; benzol will be manufactured in constantly increasing quantity, but the total supply can never fill more than a small part of the engine-fuel requirement. Alcohol and shale-oil distillate, on the contrary, are main products made from raw materials of almost unlimited availability; they may be produced to fill any need, however great, willing to pay the price. Whether shale-oil distillate or alcohol will eventually become the more important engine fuel cannot wholly be foreseen; but since shale-oil is similar to crude petroleum and can be made to yield an analogous range of products, a shale-oil industry is certain to supplement and eventually to succeed the petroleum industry, and hence shale-oil distillate is bound to become eventually a prominent motor fuel.[10] Alcohol on the other hand, is not so tied up with joint products, and its career as an engine fuel will be determined almost entirely by relative economy and its acceptability to engines evolving on the basis of oil fuel. If the engine type broadens so as to fit the petroleum resource, it will at the same time be prepared to receive the aid that benzol, shale-oil and alcohol may be called upon to render.

On the whole, then, there is nothing in the substitute engine fuel situation that would dictate to the automotive industry a policy differing from that determinable upon the basis of the petroleum issue. The substitute fuels remove any physical limit as to the quantity of engine fuel that may be produced; they offer greater assistance to the situation if present standards are less rigorously adhered to and automotive apparatus becomes adapted to a less volatile fuel than gasoline; they set the bounds to which the price of engine fuel of petroleum origin can advance—a very rough approximation of this figure being relatively 50 to 60 cents per gallon—suggesting, therefore, to the automotive industry an increase in thermal efficiency competent to offset the advance in price which the substitute fuels will permit and the petroleum situation will occasion.

Future Developments

The foregoing analysis of the resources and technology underlying the prospective supply of engine fuel indicates that the continued growth of the automotive demand will soon force either an extraordinary dependence upon cracking, with concomitant increases in production costs, or else a change in the character of the fuel so as to include more and more of the material now going on the market in the form of kerosene and fuel oil. The first adjustment is limited by the physical capacity of cracking, which is largely an unknown quantity, and the extent to which fuel costs can rise without involving curtailment in the growth of the automotive industry. The second solution is dependent upon the extent to which automotive apparatus may be adapted to consume a fuel less volatile than gasoline. Running through each solution, and serving to contribute to each, is the extent to which the thermal efficiency or fuel economy of the automotive apparatus may be increased. The more rigorously the present standards of low economy and specialized requirements are adhered to by the automotive industry, the greater the weight that will fall upon cracking, the greater and more sudden the inevitable rise in fuel price and the graver the danger of of an industrial reverse.

The fuel resources in sight indicate that a normal balance between supply and demand will eventually be reached, irrespective of the policy of the automotive industry, but the adjustment will result in a basis of price and character different from that now prevailing. The danger in the situation is not that of a permanent breakdown in fuel supply through exhaustion, but of a period of enforced readjustment to new conditions of fuel supply, which may come so suddenly as to catch the automotive industry unprepared and in consequence impose a serious handicap upon its prosperity, if it does not precipitate industrial disaster.

Situation Critical

The situation is serious, indeed critical, not only because the period of readjustment is apparently almost upon us (see Fig. 1), but because there are many aspects of the situation that tend to hide the real issues and to lend a false sense of security to those armed with an excess of optimism. American economic experience affords no parallel to the present engine-fuel situation; as demand in the past has almost invariably conditioned supply in American economic practice, it is an easy assumption that this will continue to hold in unabated vigor. New discoveries of oil pools are constantly coming into prominence. While the outlook for oil production never before appeared brighter, one easily overlooks the fact that each new pool, in proportion to its magnitude, adds to the unstability of the engine-fuel structure. At this very moment of writing, gasoline is piling up in storage and it is quite possible that before the winter is over the price will decline slightly. This may readily be accepted as controverting the whole argument of the paper, if the circumstance is not recognized as an inevitable reaction to a coincidence of season and post-war industrial readjustment. Upon all this come widely heralded announcements of new fuels, with extravagant claims and secret formulas, boldly promising at one stroke an easy solution of one of the most complicated industrial problems this country faces to-day. There are indeed specious arguments for sustaining conclusions quite the reverse of those arrived at here. While one series of circumstances is operating cumulatively to render the engine fuel situation more and more unstable, another set is serving to hide the real issue.

There is scant hope, at this late date, that the automotive demand will be brought into stable adjustment with the engine-fuel supply with results wholly conducive to the prosperity of the automotive field, but such difficulties as lie in store may be tempered if the industry as a whole recognizes its responsibility in this matter and acts accordingly. The exigencies of the fuel situation now urge, but shortly will demand, that the automotive industry work toward greater fuel economy and at the same time adapt its mechanical equipment to handle a less specialized fuel than gasoline. The first can be accomplished in some degree through car design, but in the main must depend upon engine changes in favor of greater thermal efficiency. The second can be accomplished either through the development of equipment not dependent upon fuel of high volatility, so as to permit the supply of "gasoline" to expand easily, or else by inducing the engine-fuel supply to bifurcate into gasoline at present grade reserved for passenger cars, and heavier distillates to be drawn upon by trucks, tractors, etc., fitted with semi-Diesel or other type of engine suited to such fuel. Apart from the disadvantage of greater costs involved in the production and distribution of two specialized fuels in the place of a single product, and the practical difficulty of unloading the problem

[9] Gasoline can be sold cheaper than any competitor, because of the possibility of shifting part of its cost of production to the joint products.

[10] It should be remembered, however, that many years must elapse before a shale-oil industry can become established and grow to significant proportions.

on the heavy-traction section of the automotive industry, the second expedient would in reality mean merely the turning over of the raw materials of cracking to a counter demand and would leave the gasoline problem still in acute need of attention. So the economics of the situation, the dictates of resources limitations and human needs, point to an automotive engine evolved into a type fitted to gain not only higher efficiency from the fuel consumed but greater economy in respect to the activities involved in the production and distribution of the fuel. The answer then is: Greater thermal efficiency in the engine and means for gasifying liquid fuel without requiring that it first be converted by a costly manufacturing process into a highly volatile product difficult to store and to transport.

Summary

1—The automotive industry is working without due regard to the engine-fuel situation.

2—This situation is an integral part of the automotive situation and should not be left out of account.

3—Owing to the pressure of automotive demand, the supply of engine fuel is in course of change, both in respect to character and price, with danger of precipitant alterations; there arises in consequence a fuel problem which cannot be adequately solved without the active participation of the automotive industry.

4—An analysis of the problem is as follows:

(a) The domestic production of crude petroleum is nearing its maximum.

(b) The natural gasoline content of this supply is lessening.

(c) Mexico offers no relief competent to solve the issue.

(d) Substitute fuels need not enter into present consideration.

(e) The supply of engine fuel can be maintained only through an extraordinary dependence upon cracking or through changes in engine type.

(f) Cracking cannot meet the issue at a favorable price.

(g) The burden, therefore, falls upon the automotive engine, which must consequently so adapt itself as to gain higher thermal efficiency, and to use less specialized (less volatile) fuel.

5—The automotive industry should therefore at once, as an emergency measure, take steps to shape its development in the direction of increased fuel economy and less specialized requirements as to fuel, establishing for this purpose centralized machinery to study the problem in full detail; should keep the industry informed of every development in the situation; should coordinate research and design in the competing units of the industry; and should conduct basic lines of research not now adequately encompassed by individual agencies.

The Unmined Supply of Petroleum in the United States*

Estimates of Quantity Still in the Ground Vary from 5,763,000,000 to 24,500,000,000 Bbl.

By David White

Chief Geologist, U. S. Geological Survey

THE justification of an estimate so highly speculative as must be that of the petroleum resources in the ground in the United States lies in the widening angle between the flattening curve of production and the rising curve of consumption. The standards of living, the industrial power, and the prosperity of the country are to so great a degree dependent upon our oil supply, and the question of the adequacy and duration of this supply so directly concerns, at the present moment, the individual citizen, as well as the public in general, that an estimate, even if it but a scientific guess, based, with careful study, experience and judgment, on the best information available, is imperatively necessary.

In response to the growing interest of the public four estimates of the oil resources of the United States have been made. In 1908 Dr. David T. Day,† then in charge of petroleum statistics in the U. S. Geological Survey, calculated the total amount of oil originally available in the ground as ranging somewhere between a minimum of 10,000,000,000 and a maximum of 24,500,000,000 bbl. In 1915 Dr. Ralph Arnold‡ placed the original supply of oil at 9,098,557,000 bbl., of which he believed 5,763,100,000 bbl. remained in the ground at the end of 1914. The third estimate was made by the geologists of the oil and gas section of the Geological Survey for the use of the Secretary of the Interior in responding to a Senate resolution of Jan. 5, 1916, and was published in Senate Document 310, Sixty-fourth Congress, first session, Feb. 2, 1916. According to this estimate the reserve of oil available at the end of 1915 was 7,629,000,000 bbl. In the spring of 1917 the producing or possibly productive area in the Western closely reconsidered with marked conservatism by the same geologists, each studying the regions with which he had field acquaintance, with the result that the total oil available in the ground at that time was estimated at 6,182,000,000 bbl.

In the preparation of estimates in the U. S. Geological Survey consideration has been given to the general character of the geologic formations—stratigraphy, geologic history, structure—the number, thickness, continuity and pore space of sands, the curves of production, the gas pressure, the water relations, and the results of drilling in near-by or geologically similar regions. A large part of the producing or possibily productive area in the Western States has been examined and mapped by the oil and gas geologists of the Survey or is now under examination. Typical areas in the Central, Gulf and Eastern States have also been studied. Nevertheless, the criteria upon which estimates can be based vary in every degree of inadequacy in the different regions, and the quality of the results, therefore, varies with the extent and character of the data available and with the personal equation of the estimators. Necessarily the estimates for areas not yet tested, especially those remote from the producing fields, are based upon theoretical conditions, carefully considered. For most of the areas estimates were first formulated by the geologists who had studied the areas. Later, these estimates were discussed in conferences.

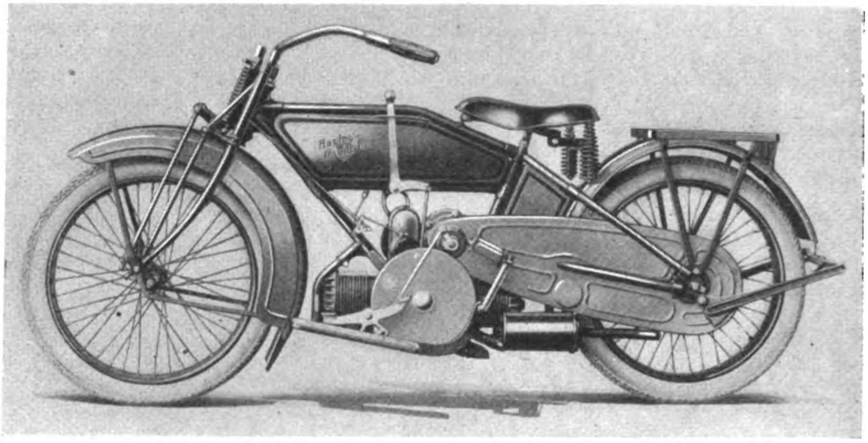
Harley-Davidson Co. Brings Out Sport Model

An Entirely New Design, Having a Two-Cylinder Opposed Engine, Multiple-Disc Clutch and Three-Speed Transmission Combined in a Unit Power Plant, Single-Chain, Inclosed Drive—A Solo Roadster of 257 Lb. Weight

AFTER having for more than a decade built motorcycles with single and two-cylinder V engines, the Harley-Davidson Co. of Milwaukee has brought out a new model fitted with a two-cylinder opposed engine. This is an entirely new design, and the cylinder displacement is considerably smaller than that of the previous Harley-Davidson twin machines, being only 35.6 cu. in. as compared with 61. The machine is known as a sport model, and is classed as a moderate weight type.

Quite a departure from conventional practice is the use of a unit power plant, which does away with the short chain drive from the engine to the transmission, formerly used by most makers of motorcycles, affording a number of forward speeds.



Harley-Davidson sport model, left side

The elimination of this chain, together with the inclosure of the final drive, insures complete protection from mud and dust of all parts of the driving mechanism, and should add greatly to the life of the machine. A first reduction in speed from the engine to the transmission is obtained by means of helical spur gears, which are inclosed and run in a bath of oil. This type of gear is used on account of its noiselessness. Lubrication of the final drive chain is secured by leading the breather pipe into the chain case, so that the oil-laden air from the crankcase is directed onto the chain.

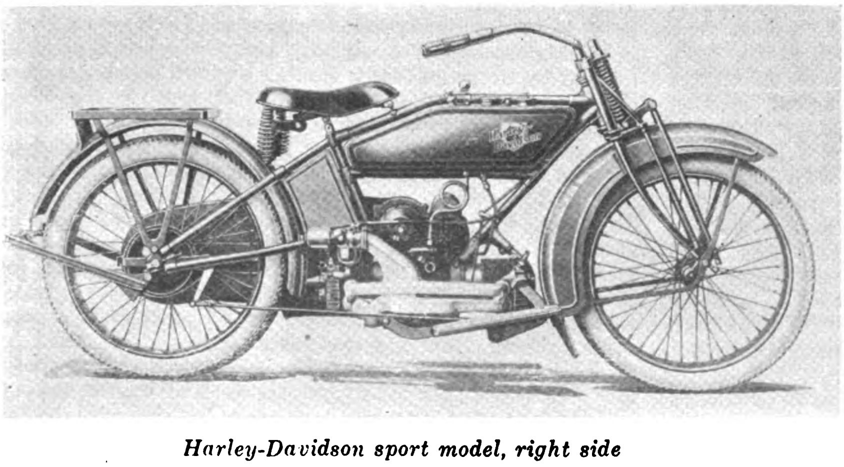
The new Harley-Davidson sport model is designed as a solo roadster for cross country work. It weighs 257 lb., and the manufacturers lay emphasis on the point that it is not a light weight machine in the sense that this term has been usually applied. A speed of 50 miles per hour can be maintained on good roads, and the engine is said to be so flexible that it will admit of throttling down to a pace which obliges the rider to use his feet to steady the machine. For power and hill climbing ability the machine is said to be the equal of any standard twin cylinder.

From an operating standpoint one of the important features of the sport model is its low center of gravity, which is due partly to the use of 26 in. wheels and partly to the type of engine fitted. The saddle position is low and well forward, and the machine is claimed to handle well in mud and sand.

The engine is of the well known two-cylinder opposed type, with cranks set at 180 deg. It has a bore of 2¾ in. and a stroke of 3 in., giving a piston displacement of 35.64 cu. in. While the rating is 6 hp., it is stated that it will develop considerably more than this.

Crankshaft Carries Balance Weights

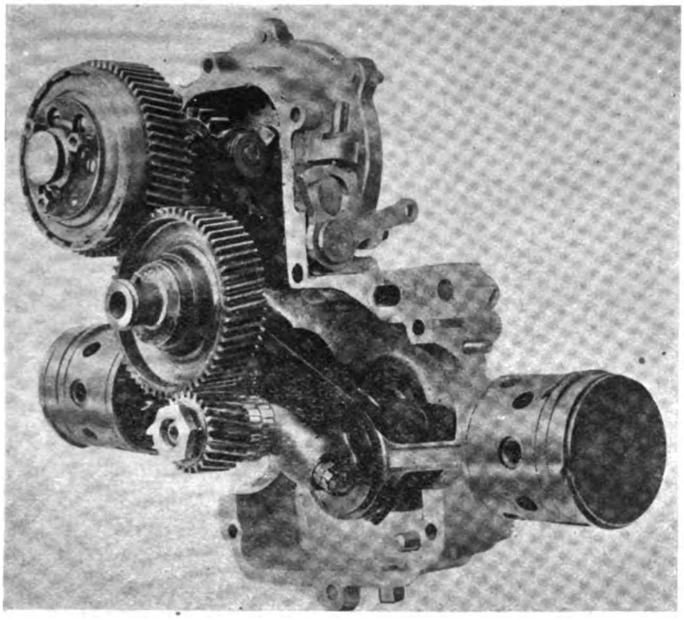
Following previous Harley-Davidson practice, roller bearings are used in the engine, both main and crank pin bearings being of this type. These bearings are made by the Harley-Davidson Co. itself. Notwithstanding the fact that a two-cylinder crankshaft with opposite throws has a very good inherent balance, balance weights are attached to the two short crank arms, so that the engine should operate with very little vibration. The method of attaching these balance weights to the crank arms is of interest, and is shown in one of the illustrations.



Harley-Davidson sport model, right side

An outside flywheel is used, and is built up of pressed steel discs, which are inclosed in a neat guard, so that the wheel will not throw any water, sand or mud onto the rider's clothing.

The valves are located at the side of the cylinders, one above the other, but not in the same vertical plane, the object in thus staggering them being to permit of operating both sets of valves from a single, horizontal camshaft. All valve ports have a clear diameter of 1¼ in. The plugs over the valves are provided with cooling fins. Only two cams are required for operating all four valves, one intake cam and one ex-



Assembly of power plant parts, showing especially the pistons, clutch and helical gearing

haust cam. The valves are actuated through the intermediary of a simple tappet lever without rollers. Cams and tappet levers operate in a bath of oil. Valve stem guides are screwed in place. All valves may be ground into their seats without removing the cylinders from the engine or the engine from the frames. It is also possible to decarbonize the engines without any great trouble, as the cylinders can be removed without taking the entire engine out of the frame.

In the design of the new engine account has been taken of the constantly deteriorating quality of motor fuel. A combination cast inlet and exhaust manifold is used, which extends between the valve ports of both cylinders and is fastened to them by means of a stud and nut at each end, a gasket insuring a gas pipe joint. That part of the intake pipe in which condensation is most likely to occur is heated by a by-pass from the exhaust pipe, to such a degree that "loading" is said to be entirely prevented. The use of this form of combination manifold does away with a good many joints and greatly simplifies the construction. A standard ¾-in. Schebler carbureter is fitted, and is provided with a cylindrical dust baffle. The latter is an air-filtering device which prevents road dust and sand from reaching the inside of the engine through the carbureter air valve.

Ignition is by a high tension magneto mounted on top of the crank case. Metric spark plugs are used, and are so located that they can be easily gotten at, yet so that their operation is not likely to be interfered with by splashing mud and water. Priming cocks are screwed into the cylinder walls close to the spark plugs, so that the gas formed by the priming charge will be in the vicinity of the plug and be sure to be fired.

Lubrication of the entire power plant is effected automatically by means of a plunger pump with rotary valve. This pump may be adjusted to feed more or less oil by lengthening or shortening the stroke of its plunger. A bull's-eye makes it possible to watch the oil feed. For emergency use a hand pump is provided.

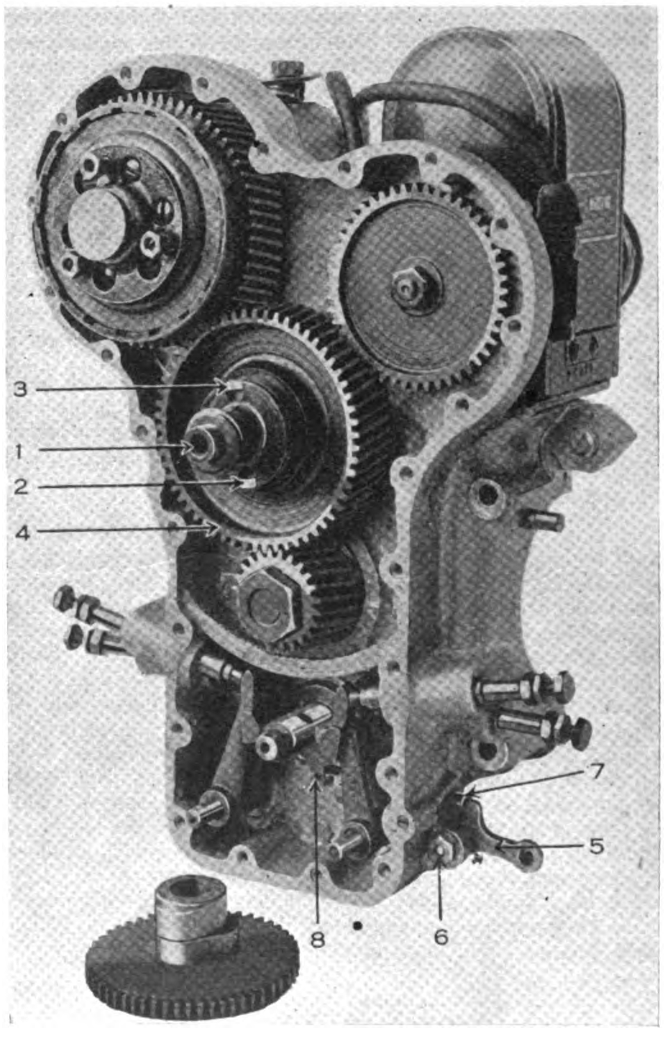
Lubrication System

The oil pump delivers the oil into the case inclosing the helical driving gears, where it serves to lubricate these gears, the bearings and the disc clutch. From this casing the oil overflows into the crank case of the engine, where it lubricates the main and crank pin bearings, the wrist pin bearings and the cylinder walls. As the transmission is located on top of the crank case, and is formed with an open base, so that there is direct communication between the crank case and the gear case, lubrication of the transmission gears is effected by the spray from the revolving crankshaft. The drive chain, transmitting the power from the transmission to the driving wheel, also receives its lubricant from this single source. It is carried to it in the form of a mist through the crank case breather valve, which discharges into the chain case. Ports are drilled in the secondary gear hub, and in the stud upon which it revolves, so that the secondary gear is made to serve as a crank case breather valve. This farther simplifies the construction. The breather pipe leads from the top of the driving gear case direct to the driving chain case.

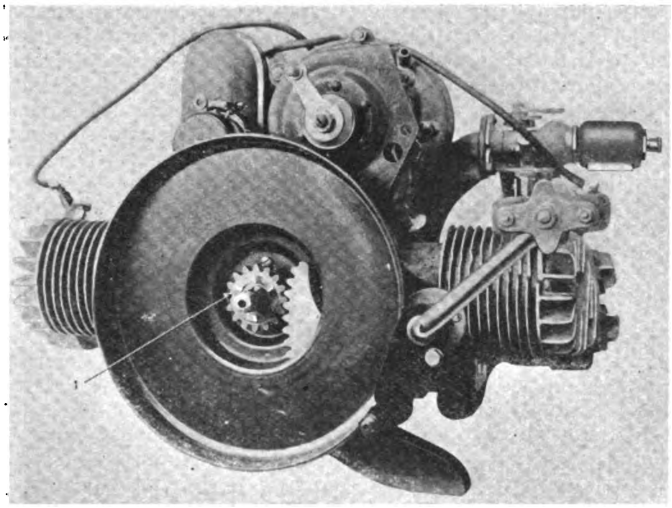
Multiple Disc-in-Oil Clutch

An innovation for the Harley-Davidson Co. is the use of a multiple disc-in-oil clutch. Owing to the fact that the clutch is located in the driving gear housing, in which there is a constant supply of oil, the use of this type of clutch does not call for any additional attention. In the earlier experimental models, a plain steel disc type of clutch was used, but this has now been replaced by a design in which one set of discs is provided with what is referred to as composition inserts. There are 13 discs in the clutch, made of saw steel carefully tempered. If adjustment of the clutch is ever called for this can be readily attended to. The clutch is controlled by a pedal convenient to the left foot of the driver.

The arrangement of the transmission is substantially the same as that of the three-speed sliding transmission used on the Standard Harley-Davidson twin motorcycle, which has already been described in AUTOMOTIVE INDUSTRIES. On the high gear a reduction of 5:1 is obtained; on the intermediate gear, 8.33:1, and on the low gear, 13.87:1. One of the



Unit power plant with gear cover removed. Valve operating mechanism at the bottom of the figure



Unit power plant with flywheel removed, showing starter gearing

greatest improvements over previous models is the elimination of the intermediate chain drive. The one remaining chain is completely inclosed, and is therefore protected against excessive wear due to dust, sand and mud getting into its links, as well as against rust. The chain being at all times kept clear and well supplied with oil, wear is very slight and adjustment is required only at long intervals. This adjustment, moreover, can be made without disturbing the chain guard. The hubs and brakes are of Harley-Davidson manufacture. Large hubs with substantial flanges, cones and ball races are used. The brake is of the contracting band type, and is claimed to hold the machine in either direction. Its drum is 7 in. in diameter and has a brake band of 1 in. width acting upon it.

The frame is of the double bar thrust type, and when the unit power plant is in place it forms a keystone construction. Seamless, high carbon steel tubing 1⅛ in. in diameter and of Nos. 12 and 16 gage is used for the frame. The steering head bearings are of the same design as those on the larger Harley-Davidson model, although slightly smaller in size. To facilitate the installation of the power plant in the frame by one man, a small shelf is provided on which the power plant can be rested just before the clamping bolts are slipped into place.

Although the center of gravity of the machine is very low, the road clearance is 5½ in. The manufacturers point out that this is equivalent to a greater road clearance with a machine of long wheel base.

Fork of Caster Type

The fork is of the trailer or caster type; it is made of round, seamless steel tubing, and features the Harley-Davidson double stem extension fork side principle. Side play and wheel shake are prevented by the balancing rocker arms. The main cushion spring is a large, resilient coil, which is placed outside the steel tube or cylinder which carries the recoil or balancing spring.

The starter is made up as a unit with the engine, and is on the left side of the machine. It turns over the engine at sufficient speed to start it readily, and may be operated with the gear shift lever in any position provided the clutch is disengaged. The starter is protected by a substantial steel shoe from mud, sand and water thrown up from the road.

One-inch tubular steel double-stem handlebars, with handlebar stems and steering bars proper made in one piece, eliminate brazed joints at top of the stems. The grip control mechanism is entirely inclosed within the handlebars. The system used is the Harley-Davidson double-acting wire control.

The tires are 26 x 3 in., which is very liberal equipment for the weight of this machine. Rims are standard CC type steel rims. A regular motorcycle saddle is fitted, and is mounted on the Harley-Davidson Ful-Floteing seatpost. The luggage carrier affords an 8 x 14 in. carrying space.

Five-inch mudguards are furnished and a large, substantial splasher flap is fitted to the front one. The rear mudguard has a removable rear section to permit ready removal of the wheel in case of tire trouble.

Gasoline and oil tanks follow very closely the lines of the tanks on the larger Harley-Davidson model, and have no exposed seam and no sharp corners. On the new model, however, the tanks are made up as one complete unit. The gasoline tank holds 3 gal. The oil tank holds 2 quarts, or enough for 400 or 500 miles under ordinary conditions.

A large muffler silences the exhaust so it is hardly noticeable. A tail pipe directs the exhaust gases away from the machine. A cutout is provided which may be readily operated by the foot without the rider taking his eyes off the road.

Acetylene as Motor Fuel

NOT much has been heard in late years regarding the use of acetylene as fuel in internal combustion engines, after experiments during the early part of the century had yielded no commercial results. Quite recently, however, references to the use of this fuel are again being met with in the European technical press, which may be a result of the gasoline famine in some countries consequent upon war conditions. Thus the *Tecknisk Ukeblad* reports that a motor transport service, running exclusively on carbide, has been maintained throughout the summer on a route 116 km. long between Kristiansand and Aaseral. Also a trial trip has just taken place with a 52 hp. motorboat, "Falken," driven by a six-cylinder Thornycroft petroleum motor, adapted to carbide by being fitted with a special vaporizer and air-mixing valve. The carbide containers, three in number, are situated on deck with pipes leading to the engine below. The Swiss Acetylene Society recently published the results of precise measurements on the gas consumption of acetylene engines. The measurements were made on a 30 hp. truck engine, and the output determined by an electric dynamometer. The engine under test made the same speed of revolution at all loads. The results were as follows:

Brake hp.	Total consumption cu. ft. atmosphere	Specific gas consumption: cu. ft. per hp. atmosphere
10.5	136	13.1
17.0	177	10.3
22.8	238	9.9
27.2	252	9.2

The FORVM

In Defense of the Bristol Fighter

By S. W. SYMONS, Lt. R. A. F.

AS a constant reader of AUTOMOTIVE INDUSTRIES and a pilot who has spent considerable time on Bristol Fighters, I cannot permit the many statements which have been printed in the American press, belittling the performance of the Bristol Fighter, to go unchallenged.

I do not blame the American press for these statements; I know full well that they emanate from official sources and that is the obvious reason for their inaccuracy.

The reported obsolescence of the Bristol Fighter might in itself pass unnoticed. You are well aware that the Bristol has been in use at the Front for the better part of two years, a long period for any machine to remain up-to-date under war conditions, and a new "Super" Bristol has been under way for several months past, though it may now never see the light of day. However, it is the statements which belittle the performance of the Bristol which I wish to criticise, and particularly those comparisons, on a purely fighting basis, between the Bristol and D.H.4. (itself obsolete) which are misleading and in many cases inaccurate.

In comparing the Bristol Fighter with the D.H.4. (or D.H.9. which has superseded it) it should be borne in mind that the D.H.4. is an armed bomber and is not intended to fight unless forced to, while the Bristol is purely a fighter and only used for bombing incidentally, though, due to its ability to take care of itself in a scrap, it has been used very successfully on "lone" photography and reconnaissance "shows" and even for trench "straffing," where usually only the lightest machines are used.

The D.H.4. and Bristol machines frequently work together. It is no uncommon thing to see a squadron of D.H.4. machines start on a bombing "show" escorted by Bristol Fighters, and if there is any fighting to be done, it is left most religiously to the Bristols.

With an expert fighting pilot and observer the D.H.4. can give an excellent account of itself in a scrap, but again, not being a fighting machine, neither pilot nor observer is picked for his fighting qualities, and even the most expert would be at a disadvantage owing to the D.H.4. having such poor stunting qualities, so essential for fighting. The Bristol, on the other hand, is designed primarily for fighting and both pilot and observer are given a special training in gunnery and fighting practice, and, of vital importance, the pilot must qualify as a "stunt artist" before going overseas. In stunting capacity the Bristol is only excelled by some of the small and fast scouts.

In regard to actual work in France, I can only say that the Bristol Fighter was feared by the Huns as much, if not more, than any other British machine and they had no two-seater to touch it in performance. I have known personally of many occasions when a single Bristol has been set upon by six or more Hun scouts and got away with it, with at least one Hun sent "west." It is a peculiarity of the Bristol, due largely to the rear gun, that the Huns will not attack a single machine unless they outnumber it at least four to one. In more recent scraps, where large formations have been employed, I have known of several cases where formations of six to twelve Bristols have run into the famous circus, numbering anything from 25 to 50 Albatross and Fokker scouts, and again come out best. My own squadron one morning brought down thirteen Huns in a 2-hr. "dog fight" without the loss of a single machine. A pal of mine, in another Bristol squadron, started out with a formation of twelve and came back with a bag of 15 Huns and no losses. A flying officer in my squadron went to France in January, 1918, had his first scrap late in February and between that time and September, had—officially—destroyed 34 Hun planes, had been decorated three times, and risen to the rank of Major; these are but a few Bristol records; they could be multiplied by the hundreds.

To turn in detail to some of the statements and criticisms in the American press, statements which the press cannot be held responsible for since, as before noted, they presumably come from official sources.

In your issue for Sept. 26, 1918, page 548, the types of engines used in the Bristol are listed, and a statement of performance is given.

The engines listed are the 190 Rolls, 150 and 200 Hispano, and the 200 B.H.P. As a matter of fact the only engine used to any great extent is the Rolls, the use of the other types being practically negligible, and the 190 Rolls was superseded in December, 1917, by the 264 Rolls (sometimes known as the 275). This engine is really a highly improved 190, but the 40 per cent increase in power had a marvellous effect on the performance of the plane. Apparently this information had not been given out in the States in time for publication in the issue of Sept. 26 of AUTOMOTIVE INDUSTRIES. In other respects the report is sufficiently accurate, except that the front gun carries 500 rounds instead of 88.

As regards the failures experienced in the early part of 1918, noted in your issue of Sept. 5, page 404, which apparently damned the machine in the eyes of Americans, these were undoubtedly serious, though luckily very few. They were due entirely to slight changes in wing construction, made by the manufacturers and changed as soon as the results came to light. All existing machines were also modified so that a repetition was made impossible. When it is considered that Bristols have been dived at over 300 m.p.h. (I myself have been in a dive at over 230 m.p.h.) any rough handling in pulling out, or a slight reduction in wing strength, is bound to result in failure, yet Bristols are constructed so that pilots handle them as though it were not possible to break them and you can do things with a Bristol which would make a D.H.4. collapse.

The real reason the Bristol was washed out in the U. S. A. is that the Liberty engine did not suit it. It was too heavy and too powerful and it is a pity that this reason was not frankly stated, though it was obviously due to the mysterious workings of the official mind.

In conclusion I cannot but admire the frankness with which the American press has reviewed the airplane situation and admitted the many deplorable mistakes, mistakes which have now happily been completely cleared up and cannot now affect the winning of the war.

Recovery of Manganese from Slag

A GERMAN patent, No. 307,393, of March 7, 1916, describes means for recovering manganese from low-percentage manganese-carrying blast-furnace slag. In an electrical furnace a sump-bath of iron, or clippings and turnings, is melted without access of air, and into this the blast-furnace slag of basic proportion of 1 to 0.8 is put, and the bath raised to the highest temperature possible. When fusion has taken place, as much lime is added as the fluidity of the bath will permit. A better reduction of the manganese is thereby effected, due to the increased basic qualities of the slag. The sulphur and manganese compound of the blast-furnace slag is broken up, and the sulphur carried over to the final slag. To the whole molten bath a reducing agent is then added in the form of small pieces of coke, whereupon the reduction of the manganese and oxygen compounds takes place according to the equation $MnO + C = Mn + CO$. The reduction is greatly facilitated by the use of lime and coke, prepared in the electrical furnace, where, under the action of the electric arc, calcium carbide is formed, which substance serves as the carrier of the carbon required. The molten iron takes up the reduced manganese, forming a ferro-alloy. Manganese is used as an alloy in steel and hardens the latter.

Social Surroundings Have Important Bearing on All Labor Questions

Comfort and Home Life of the Worker Will Modify Extent and Acuteness of Unrest and Migration

By Harry Tipper

FOLLOWING our last week's article, giving some particulars as to the condition of labor in the automotive field in this country, it is necessary to consider the general figures of the case not only, but also the prospects of difficulty with organized labor in this field during the period.

It is to be observed that since the armistice was declared there have been a number of strikes among skilled workers in several industries and in many localities, asking either for higher wages or for shorter hours, and apparently aimed at the prospective reductions in labor prices which are likely to occur and adopted as a means of strengthening the position of the organized labor bodies under the circumstances. These strikes have not become acute, and in most cases they have been settled very promptly. They indicate rather the beginning of the post-war period of unrest, which will be accentuated in proportion to the difficulties met in redistributing the labor to take care of the present industrial requirement.

It is obvious that in Europe the organized labor bodies are determined upon carrying out the very radical socialistic program which they have adopted during the war period and which has been expressed in the platforms emanating from their conferences. It is significant to note that the trouble from general strikes in Great Britain is more widespread and covers a larger number of industries than at almost any other previous time. It is also evident that the strikers present a much more determined front and a much more complete and effective organization than they have been able to show at any other period.

Political Demands of Organized Labor

It is not likely that we shall be troubled in this country with the severe conflict between labor and capital which is occurring in Great Britain, but the example of the European countries and the presence of a considerable body of radical opinion among the labor organizations would suggest that some severe labor unrest will occur based upon the desires of the organized bodies of labor for a larger control politically and industrially at the present time when public opinion is sufficiently fluid.

The platforms of the organized labor conferences in various states continue to exhibit demands which are mainly political and which are radically socialistic in their point of view. It is to be noted that the demands made on these platforms have extended themselves politically very much further than any labor organization permitted before the war began. In several of these adopted resolutions of various state conferences of the labor federations the demand for the government ownership of public utilities has been extended, so that the demand now takes in the ownership and distribution of coal, food products and of other important matters. The only difference, therefore, between the situation in Great Britain and the situation in this country lies in the relative weakness of the labor organization, which prevents their passing to the extreme measures that are being adopted on the other side.

The power and influence of organized labor have been greatly extended during the war, until this body, variously estimated as comprising from 14 to 20 per cent of the total supply of labor in the country, has exercised an influence so far beyond the boundaries of its own organization, in the last few months, that in many industries its effect is as great as though it comprised 80 or 90 per cent of the total labor instead of a minority. It is this increase in political influence which makes it impossible to predict with safety the demands of labor and its willingness to accept the process of readjustment without a more or less severe conflict. The necessity for redistribution of skilled labor from one part of the country to another and from one type of work to another, with the necessary period of unemployment, is in itself a cause for social unrest and discontent. People do not move readily from their homes unless the necessity is severe, neither do they accept a change in their economic condition which involves the acceptance of less pay until necessity compels them to do so.

Question of Wages Is Minor

In the meantime the enforced idleness and the comparative sacrifice taken together with the ceaseless activities of the radicals are calculated to lead to unrest and to lay the foundation for further difficulties between the organized bodies of labor and the industrial owner. It is probable that idleness and the social causes of discontent are at all times more important in their bearing upon labor troubles than the question of wages *per se*. The question of housing, the character of the surroundings and the bearing of this on comfortable home life are always important, and at no time of greater importance than at the present.

At South Bend, Ind., this week the Studebaker Corporation presented to the citizens of South Bend their plans for the addition of new factories which would require 12,000 workers besides those already employed. At the lowest estimation this means an addition of 40,000 people to the population of a city whose present population is around 75,000. It was interesting to note that the great concern of the Studebaker Corporation in presenting this matter was the question of the provision of proper houses, schools, churches and the accompanying public improvements in order that the workmen could be secured and induced to remain.

The relations between the Studebaker Corporation and its employees are evidently very friendly, and the plans which the company have in mind indicate that they expect

to make developments in profit sharing, etc., which will increase this amiable contact. The corporation recognizes nevertheless that nothing which it can do in the way of organization developments, in giving the worker a share in the responsibility for the enterprise, can be effective unless the social surroundings are at least reasonably comfortable.

Large bodies of skilled and unskilled laborers were moved during the war period into specific locations in order that the urgent requirements of the war could be met. The Government did a great deal of work in housing these workers and the immediate problem was solved.

In the redistribution of labor from the concentrated necessities of the war to the development of peaceful occupation these social surroundings will have a great bearing upon the labor unrest, both as to its extent and acuteness. Thousands of workers will not move back to their old places, and cities which have not been faced with a large amount of unemployment because of the cancellation of war contracts will be faced with an unemployment problem due to the migration of workers, either from war industries or from the demobilization, who have decided not to go back either to their old life or to their old occupation.

The general unemployment figures show an increased number of skilled and unskilled workers who are idle, and this idleness will automatically breed labor trouble, discontent and unrest, and may lead to some disorder. In this respect the automotive field is interested not only in its own labor problem but in the general labor conditions throughout the whole country, because the stability of labor in this particular industry and the relations between employer and labor will be directly affected by the surrounding conditions in other industries in the immediate localities or general territory.

All things considered, this is the proper time for every manufacturer who desires to stabilize his labor and to meet the return to peaceful production with a minimum of trouble to begin the development of those organization plans which may be necessary to establish the proper basis of confidence between the employer and his employee. This point cannot be emphasized too strongly. The platforms of the state labor conferences show that the political influence and the desire for control are extending the demands of the labor organization and leading directly toward experimental and socialistic legislation and further conflict industrially. The unfortunate difficulties in the way of a rapid readjustment will add to the force of these demands the idleness and the social unrest which always accompany any large necessities of that kind.

Changes May Invite Disaster

It is becoming clearer all the time, from the progress of conditions in the older countries, that the growth of labor organizations to the point of control will so seriously change the political and industrial aspect as to invite disaster. It is a question whether in the older countries the matter can be solved without an experimental period of socialistic government. The tendency in this direction has gone so far and the movement has acquired such momentum that such a conclusion is inevitable.

In this country the strength of organized labor is not sufficient, neither is the movement in this direction of such proportions that experimental legislation need be considered inevitable. It is still possible to solve the problem without seriously changing our fundamental practices in the governmental, industrial and social relations, but this depends entirely upon the action of the manufacturer and how far he is willing to go in taking the worker into discussions which establish the conditions of his work, the extent to which he is prepared to share the profits of the business with the worker and the distance he expects to travel in the analysis of the fundamental requirements of this proposition.

The present situation is not satisfactory either to the worker or to the manufacturer. The worker will disregard the mandate of his own executive council when there is any local advantage to be gained thereby just as readily as he will disregard the necessities of the manufacturer. The present labor organization is incapable of offering more than a temporary settlement. No organization of manufacturers can do more. The manufacturer must decide whether he will bargain collectively, inside his own organization with his own workers, or whether he will bargain collectively with the outside organized labor body. He must decide whether he will fight for control against the constantly increasing political power of organized labor and the constant tendency toward more radical demands, or whether he will gather together with his own workers in a group unified in purpose so that it can fight for its own place in the industrial world.

The practical considerations of the effect of these things upon the amount of production per man and upon the other economic items is beside the question at the moment because the whole fabric of industry is threatened with severe political readjustments unless the matter is solved or at least the basis of solution is made.

Political Power Not Understood

Even now the manufacturer does not realize the industrial significance of the present attempt in some quarters, backed by many of the labor organizations, to put the railroads under Government ownership. Even now the increase in political power of organized labor is not properly understood. It is a question whether any manufacturer realizes the extent to which the professional classes and the salaried classes of employees are in sympathy with some experiments in Government ownership and other socialistic tendencies. There is no sympathy among the large body of citizens of this country for the industrial aristocracy controlled exclusively by a few private individuals and passing no share of the responsibility to the worker. There is a great desire among the large body of citizens for an orderly solution of these industrial problems of labor which will avoid the acute difficulties in which the older countries find themselves, which will prevent us from rushing into experimental legislation of a bureaucratic nature and which will at the same time give the worker some share in the responsibility for the conditions of his own work and some share in the common object of the industrial organization of which he is a part.

Socially, politically and industrially we are in a period of change, and the industrial so intimately affects the social and political that all these changes will react one upon the other, and the action of the manufacturer in dealing with the labor problem in the next few years may govern the tendency of our political development and the conditions of our social existence.

THE first batch of airplanes ceded by the British Government to Chile has reached Valparaiso. It will form the nucleus of the new Chilean Air Service, which, as a start, will consist of 14 seaplanes and 50 airplanes, all machines originally built for the British air services. Major Huston, of the British Flying Corps, is to act as chief instructor of the new force and Engineer-Lieutenant Solano is to be the technical head of the naval section of the service. The first Chilean naval base will be the island of Omiriguina, almost in the middle of Talcahuano Bay.

Over 1200 at S. A. E. Victory Dinner

NEW YORK, Feb. 7—That the automotive future holds even greater opportunities and presents engineering problems of more import than the past was the theme of the Victory dinner held by the Society of Automotive Engineers last night and attended by more than 1200 members and guests of the society. Speakers included C. F. Kettering, president of the S. A. E.; Charles M. Manly, president-elect of the S. A. E.; Alfred N. Reeves, general manager of the N. A. C. C.; John N. Willys and George F. Houston of the Wright-Martin Aircraft Corp. Job E. Hedges was toastmaster.

Discussing aeronautics, George F. Houston briefly presented a problem that is probably of as great importance to the automotive industry as any at this time, the present and future of aviation. The past, he declared, referring to the war, was a testimonial to the engineering and productive skill of the American automotive industry, the present—"the less said the better"—but the future, he is certain, will find the airplane and the airship firmly established and accepted in an important niche in the commercial world.

War Has Developed Co-operation

The engineer, said C. F. Kettering, urging wide co-operation, who closes the door of his research department "shuts out more valuable information than he keeps in." The war, he said, has developed co-operation between automotive engineers to the highest degree, and that co-operation must be continued to insure solution of the huge problems before us.

Capital must recognize its obligations to labor, and labor in turn must recognize its debt to capital, said John N. Willys, who told of his plan to divide the profits of his various companies with the workers "above a just and reasonable wage compensation." The Ford plan, he said, not only provided the workers with greater remuneration, but increased their incentive and consequently their productive output, and he stated frankly that if the clock could be turned back he would follow the Ford plan in less than 24 hours after its inauguration.

Alfred Reeves, discussing the past year and the general governmental attitude toward the industry, and the future of the automobile, said that the industry is now recognized as vital and important, and chiefly utilitarian.

Others at the speakers' table included: H. R. Sutphen, president of the National Association of Engine & Boat Manufacturers; F. H. Russell, president of the Aircraft Manufacturers' Association; Camillo Cerruti, chief, Italian Military Mission in the United States; C. W. Stiger; Capt. E. C. Hugh, British War Mission; Capt. George Sykes, British War Mission; C. E. Thompson, president of the Motor and Accessory Manufacturers' Association, and Col. A. O. Seaman, Motor Transport Corps.

Annual Dinner of the Society of Automotive Engineers, Feb. 6, 1919

S. A. E. Annual Meeting Concludes

Three-Day Meeting Well Attended—Papers Centered Around War Accomplishments and the Fuel Situation—Dinner Attendance a Record One

NEW YORK, Feb. 8—One of the most valuable meetings ever held by the Society of Automotive Engineers came to a close yesterday. The three-day session embodied a program covering the vital developments in all phases of automotive activity. The high spots were undoubtedly the discussion of the influence of aeronautic practice on future motor car design and the symposium on the fuel situation, which occupied the attention of the members during an entire forenoon.

Higher standards of manufacture are sure to result from the lessons gained in airplane work. It was predicted by the three engineers—H. M. Crane, O. E. Hunt and Howard Marmon—that in the future we will see much greater co-operation among engineers as a result of the general discussion in laying out the Liberty engine and other airplane developments during the war. While it is true that the automobile and automotive industry has always been distinguished for the great amount of co-operation existing between even competing concerns, the war has carried that co-operation to a far greater extent, and it seems certain that the engineers who got together on airplane development, as well as on other phases of war work, will continue to co-operate in the future.

Seriousness of Fuel Situation Emphasized

The seriousness of the fuel situation was brought forcibly to the attention of the membership during the meeting, and it seems certain that out of the discussion will come a Fuel Division of the Society which will take care of this development and co-ordinate the efforts of the engineering profession and the refining industry. This matter is discussed more fully elsewhere in this issue.

It is regrettable that there was not time at the meeting for discussions. There were a great number of papers which were well chosen and dealt with vital questions, but they could not be discussed because of lack of time. Surely a great many thoughts must have been suggested by the reading of these papers, but they could not be given expression. It would seem that in the future it would be better to have either shorter or fewer papers in order to permit the membership at large to make comments or ask questions.

Sessions Well Attended

The attendance was excellent, keeping the auditorium of the Engineering Societies Building practically filled at all times. It was distinctly noticeable that the crowd was a shifting one, specialists from each of the different fields attending the meeting which most interested them. The broad nature of the work of the Society was brought out more strongly in this way than ever.

One of the features of the arrangement of the program was the grouping of the subjects so that it permitted of the attendance of those interested in any topic at the particular meeting which most concerned them. In this way the topics were covered thoroughly at a single session, and had there been opportunity for discussion it is quite certain that it would have been highly important because the leaders of the respective fields were in attendance at each of the sessions.

The final feature of the S. A. E. program was the banquet held at the Hotel Astor. This was attended by 1300 members and guests, and was one of the greatest affairs of the kind that the Society has ever held. The demand for seats was so great that although the largest banquet hall in the city was utilized, there were many who could not secure accommodations. President C. F. Kettering closed his highly successful year by introducing the toastmaster, Job E. Hedges, who presided on this occasion. Among the other speakers were Al Reeves of the N. A. C. C.; the new president-elect, C. M. Manly, and John N. Willys.

Kettering's Novel Theory

One of the most interesting phases of the professional session was the presentation of an entirely novel theory on what really happens within the cylinder of an internal combustion engine. C. F. Kettering spoke of the formation of secondary products within the cylinder, these being very often of a detonating nature causing knocks which have hitherto been classified as pre-ignition knocks. While Mr. Kettering did not present any scientific proof regarding his theory, he stated that he had reason to believe that some of the secondary compounds formed were acetylene gases. Mr. Kettering illustrated his address in his inimitable way by comparing the molecules in a given quantity of fuel with the potatoes in a bushel basket. He said that if the potatoes were all put in an oven for a sufficient length of time to cook, those of average size, the little ones, would be burned, while the large ones would be raw. This, he said, is what happens to a fuel with a number of constituents of different boiling points. The result is that some of them are submitted within the cylinder to temperatures which cause cracking, thus giving rise to the hydrocarbon secondary compounds which may be of a detonating nature, causing sudden high pressures to be reached, giving momentary but acute bearing stresses.

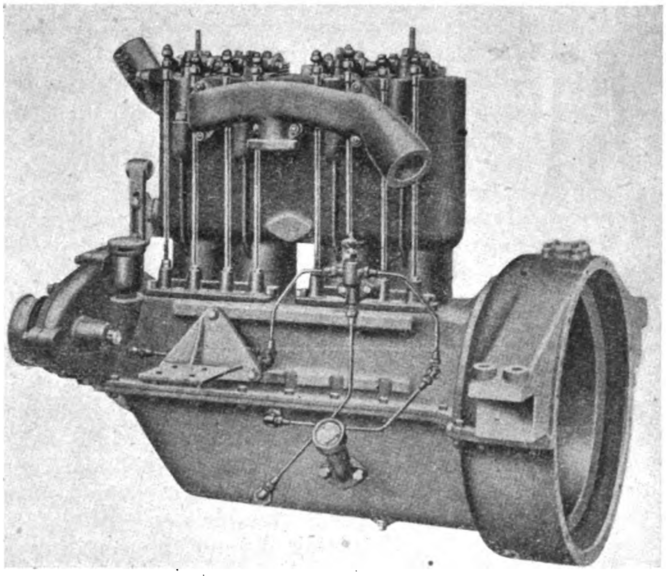
Membership Manifests Keen Interest

Throughout the entire session, the influence of Past-President Kettering's brilliant wit and effective graphic method of presentation made itself felt in creating a keen interest in what are more or less abstruse subjects, even to those who follow engineering practice. An instance of this was where Mr. Kettering showed the lack of value of chemical formulas as pertaining to the hydrocarbon series, where the same hydrogen contents and, in fact, the same contents of other elements, produced entirely dissimilar compounds because of the different arrangement of the atoms.

The program was well balanced, including a discussion of airplanes, tractors, motor trucks, motor boats, as well as automobiles and the fundamental problems which are equally applicable to all. On the tractor paper there was some discussion regarding economy, showing a surprising difference between the results obtained by British users and those in the United States. It was shown that on the other side where official tests had been conducted the fuel economy was much less than that experienced in the United States.

Gray Victory Four-Cylinder Engine

To Be Made in a Passenger Car Type with Aluminum Base and Bell Housing and in a Truck and Tractor Type in An All Cast Iron Construction



Gray Victory engine, left side

A FOUR-CYLINDER block cast engine of 3½ in. bore by 5 in. stroke has been put in production by the Gray Motor Co., Detroit, Mich. It is of the valve-in-head type, and is intended both for passenger cars and for trucks and tractors. Special emphasis is laid by the manufacturers on the provisions made in the engine for vaporizing the fuel, and high efficiency and great economy are claimed with the present grade of gasoline.

All four cylinders are cast in a block, together with the upper half of the crankcase. As the cylinder heads are separate from the cylinder block, it is possible to completely machine the compression spaces, and thus insure uniform compression in all cylinders. The cylinder bores are ground to size, and the cylinders are offset from the crankshaft axis to reduce the mean side thrust of the pistons against the cylinder walls. Inlet and exhaust passages are cored in the cylinder head, and there are two hot spots which are claimed to insure thorough vaporization of the fuel, and consequent complete combustion. A McKim gasket is placed between the cylinder block and head, and the head is held in place by means of heat-treated cap screws fitted with lock washers. The bottom half of the crankcase is made of cast iron for truck and tractor engines, and of aluminum for passenger car engines.

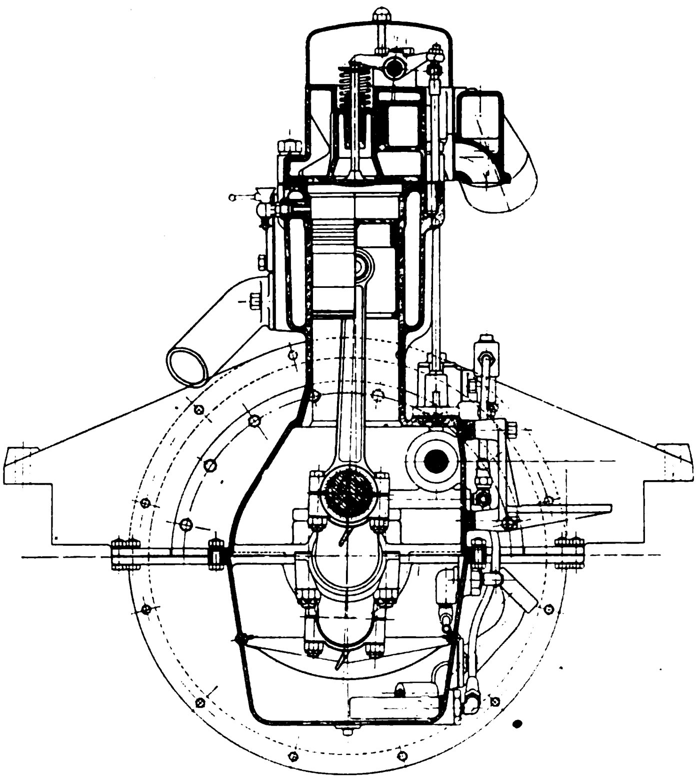
Both sets of valves are interchangeable, and in order to permit of making them of large sizes, the cylinders are counter-bored from the top end. The effective diameter of each valve is 1 21/32 in. The valves have carbon steel stems and cast iron heads, the latter of 2¼ in. outside diameter. The pistons are of conventional design, of cast iron, and are provided with three diagonally split expansion rings each. The connecting-rods are I-section drop forgings and measure 9¼ in. between centers. The crank pin bearings are 1¾ in. in diameter, by 2 in. long, and are made of die cast babbitt. Bearing caps are held in position by nickel steel bolts with castle nuts and cotter pins.

The crankshaft is made of 0.40-0.50 per cent carbon steel, heat treated and ground. It is supported in three die cast babbitt bushings, all 2 in. in diameter, and of the following lengths: (front to rear) 2¾ in., 2 in. 3⅝ in. The bearing caps are made of malleable iron, and are held to the cylinder block by means of heat treated studs fitted with castle nuts and cotter pins. Laminated shims are placed between the caps and the upper half of the bearing.

Bearing Dimensions

A three bearing cam shaft is used, made from low carbon steel, carbonized and ground. This shaft is 1 1/16 in. in diameter, and has its bearings directly on the cast iron of the cylinder block. The dimensions of the bearings are as follows: (front to rear): 1 13/16 x 2½ in., 1¾ x 2 in., and 1 11/16 x 2 in. For driving the camshaft, use is made of helical toothed gears, cut with 10 pitch teeth of ⅞ in. face. The pinion on the crankshaft and the magneto driving gear are of steel, while the gear on the camshaft is made of cast iron. The timing gears are inclosed by a malleable iron cover, the hub on which for the crankshaft is turned off cylindrically to form the third point of support for the engine. This cover is held in place rigidly by means of cap screws, lock washers and dowel pins.

Oil is fed to the three main crankshaft bearings under pressure by means of a plunger pump operated from an eccentric on the camshaft. The plunger of this pump, instead of moving in a horizontal plane, has an up and down motion. In addition to supplying oil to the main crankshaft bearings, oil is delivered from this pump to the timing gears, and to the connecting-rod splash troughs. All other interior parts, including the camshaft bearings, pistons, connecting-rod bearings and cylinders, are lubricated by splash. Oil is drawn from the main oil base through a fine mesh screen. The base will hold 5 quarts of oil, and is provided with a positive dial



Cross section through cylinder

indicator showing the oil level. As a precautionary measure, when the gage shows "empty," there is still a certain amount of oil in the base.

The engine is designed to take a standard 1 inch carbureter. Either a horizontal or a vertical outlet carbureter can be used, the vertical outlet type going on the left hand side, and fastening to the inlet manifold, while the horizontal outlet type is placed on the right hand side, and connects directly to the cylinder block. With the horizontal type carbureter the intake passage leads through the space between cylinders Nos. 2 and 3.

The flywheel is secured to an integral flange of the crankshaft by means of six heat-treated bolts. It is regularly furnished to accommodate standard clutches used in connection with the No. 3 S. A. E. bell housing.

Provision for Electrical Equipment

Provision is made for fitting a complete electrical equipment. A starting motor flange is provided on the detachable bell housing, which is of the No. 3 S. A. E. size. An ignition generator or plain lighting generator, a magneto or both can be mounted on the detachable magneto or generator bracket, and can be driven by a standard two bearing magneto shaft and coupling. A bell housing of cast iron is furnished for truck and tractor work, and of aluminum for passenger car work.

The cooling system is designed for thermo-siphon circulation, and the water connections are made appropriately large, the inlet being 2 in. in diameter, and the outlet 2¼ in. A malleable iron adjustable fan bracket is provided. A drop forged steel, quadruple jaw, roller handle crank is furnished with the engine.

The piston displacement of this engine is 192.4 cu. in. and its N. A. C. C. rating is 19.6 hp., while on the dynamometer the engine shows 34.6 hp. A horsepower and torque curve chart is shown herewith. The engine complete with cast iron base and bell housing weighs 495 lb.

Fan and magneto drive and magneto bracket

Preferential Tariff for Belgium Proposed

AUTOMOBILE travel in Belgium is still full of difficulties. Roads in the devastated area are in terrible condition, being full of holes and most destructive of springs and the general mechanism of the car. Gasoline is only obtainable in a few localities, and its cost is from $1.50 to $2.60 per gal. Tires are rare, a 36-in. casing costing from $100 to $120.

The Belgian Society of Automobile Manufacturers has already held a meeting, at which a committee was elected and new members admitted. Messrs. Gregoire, Deconinck and Dejong were elected as delegates to attend the conference of recognized Syndicates of Automobile Manufacturers at Paris next month. This conference, which will be attended by delegates from England, France, America and Belgium, will consider the advisability of recommending a preferential tariff for Belgian automobile manufacturers who existed before the war, and whose capital is entirely of Belgian origin. The proposal is being made by the British Society of Motor Manufacturers and Traders.

Detroit Demands Gasoline Meters

DETROIT, Feb. 10—An ordinance adopted by the common council of Highland Park, a suburb of this city, requires the installation of a meter in every gasoline station showing the consumers how much fuel they are actually receiving.

6140 Motor Vehicles in Switzerland

BERNE, Jan. 5—According to statistics of the Automobile Club of Switzerland, at the end of 1917 there were 6140 motor vehicles in Switzerland, of which 4934 were touring cars and 1206 motor lorries. There were 15 firms in the Helvetic confederation, and these had produced 2565 of the total number, the remaining 3575 representing 43 foreign makes. Fiat was the foreign firm with the largest number of vehicles in Switzerland, 283 touring cars and 15 lorries. Of the foreign nations supplying vehicles France came first, Germany second, America third, Italy fourth and Belgium fifth. British cars were not listed separately.

Douglas' Automatic Airplane Ignition Interrupter

A Safety Device Stopping the Engine Instantly When Propeller Breaks or Other Serious Breakage Occurs

BREAKAGE of airplane propellers in flight, or of other important parts, resulting in a seriously unbalanced condition of the power plant, often proves fatal to the pilot. An instrument designed to prevent such results, known as the interrupter, has been invented by Theodore Douglas, president of the Duplex Engine Governor Co., Inc., Brooklyn, N. Y. It was developed under the auspices of the National Advisory Committee for Aeronautics.

The function of the instrument is to automatically interrupt engine ignition, thereby stopping power development, in the event of the propeller breaking, etc. In non-war flying the danger of such breakage is fortunately not serious, though it is always present. Under war conditions, on the other hand, such breakages, accidental or from gun-fire, are very frequent and in a large percentage of cases end fatally.

The tendency of a tractor plane, in the event of its propeller breaking, is to go into a dive, and of a pusher plane to go into a tail-stall. Under such conditions either type of machine is apt to pass into a spin as a result of the unbroken propeller blade tending to swing the machine around a neutral axis. The resulting intense vibration is apt to break a gasoline line, and the continued exhaust of the engine into the gasoline-charged atmosphere may cause a fire. Sometimes the most perfect mental and physical co-ordination on the part of the pilot fails to prevent this, since the brain and hand can seldom act quickly enough, as many thoroughly understood accidents of this nature attest. This manual limitation will be better realized when it is considered that the time of one engine revolution assuming full throttle varies from one twenty-third to one twenty-seventh of a second.

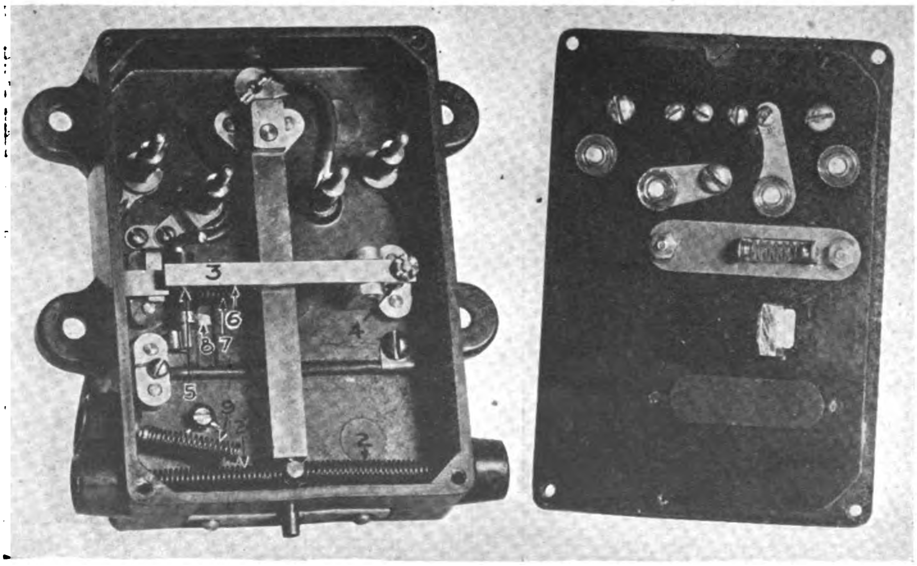
The interrupter supplements the action of the pilot in such instances, and through practically instantaneous action interrupts the power development, thereby confining the danger to the initial breakage. The instrument is thought to be particularly desirable on twin-engine machines, as such an accident happening to one engine would cause the good engine to tend to suddenly swing the machine around and probably into a spin. On such machines the interrupter may be so installed as to instantly cut out both engines, thus maintaining an approximately normal flying position. The pilot then has the alternative of making a landing with dead engines, or of switching off his damaged engine and continuing his flight with his good engine at reduced speed.

The Design

The instrument consists essentially of a suitably pivoted metal bar, so mounted as to swing in a plane transverse to the axis of rotation of the propeller. By means of tension springs 2-2, the free movement of this bar is confined, under normal airplane operating conditions, to a very limited arc in its plane of movement. The amplitude of this movement is determined by the weight of the bar, the intensity and frequency of the transverse vibrations of the engine, and the opposing strength of the springs confining it. The extended end of the trigger 3 is constantly pressed toward the floor of the instrument by the compression spring 4, and is designed to engage the latch 5. On the under side of the trigger 3 there is an inclined surface 6, by which the trigger is raised. A ball-pointed hardened steel screw is fitted into the bar directly beneath the trigger, and is designed to engage an inclined surface and thus to lift the trigger when the swing of the bar is sufficient. When the trigger is lifted the latch 5, held under tension by spring 7, is released and moves out of engagement with the trigger. Cam 8 serves for resetting the latch by rotating it back into position by means of the push button 10 from the outside of the instrument.

The compression spring 9, presenting an unbalanced force, is designed to prevent the bar from disengaging latch 5 as a result of cylinder misses coinciding with bad vibration periods of the engine, etc., thus increasing the amplitude of the swing of the bar through synchronism, or from lateral shocks to which the plane may be subjected in landing. An intense oscillating shock transverse to the axis of the engine, such as an unbalanced engine-propeller torque reaction resulting from the breaking of a propeller at speed, are the kinds of shock intended to operate the instrument, and to which it is claimed to immediately respond. Under such conditions the bar will swing through its full amplitude, raise the trigger, which releases the latch, and thus interrupt the ignition by grounding the magnetos. From the interrupter terminals 11 and 12, wires are connected to the grounding terminals of the magnetos, and from the terminal 13 of the interrupter a wire is connected to the engine ground. On the disengagement of latch 5 a triple contact is made between the interrupter terminals 11, 12 and 13.

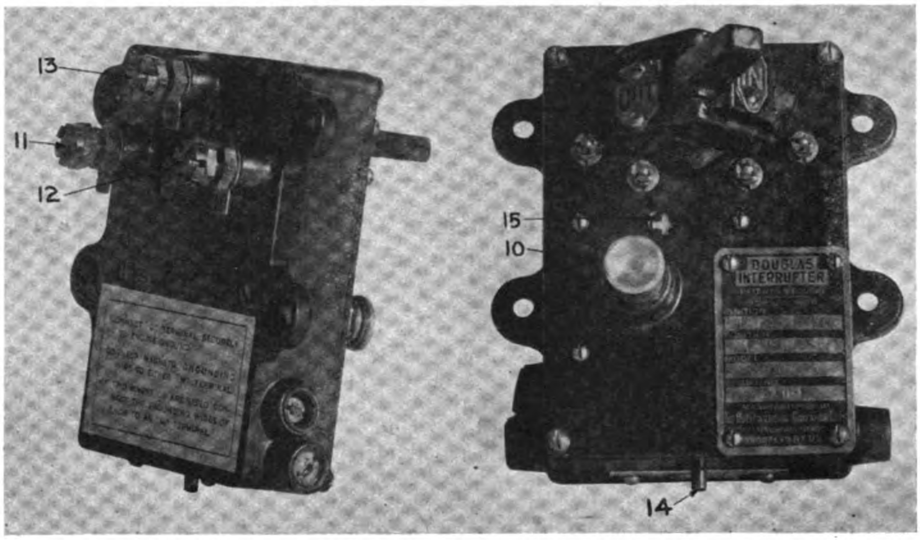
Provision is made to enable the pilot to make a rapid test of the operation of the interrupter before each flight. The handle 14, which projects through a slot in the end of the instrument, is pushed gently to the left until the red spot 15 of the tell-tale,



The interrupter with cover removed

which bears a luminous cross for night flying, appears. Before the engine stops the instrument may be reset by pressing down on the button 10 until the red spot of the tell-tale disappears. Should the engine not stop it would indicate that either the interrupter switch is in the wrong position or that its wiring system, etc., is defective.

A manually operated switch is provided with each instrument by which the interrupter may be thrown into and out of the grounding circuit as desired.



The interrupter complete, front and rear views

Types of Interrupters

Interrupters are furnished of two general types, maker and breaker instruments, and in several models to best suit various engine and airplane conditions.

Maker-instruments, such as the one just described, are intended for magneto ignition engines, in which case there is no flow of current through the instrument, except at the moment of interrupting the ignition.

Breaker-instruments are intended for Liberty engines, using the Delco system, where the current flows constantly through the instrument, and where two separate circuits are provided, because of the double distributer system used on these engines. The interruption of the ignition results from opening these circuits.

Different Models

The interrupter is manufactured in five models, adapting it to the two general ignition systems employed—magneto and battery—and to different engine locations, on the fuselage and in the wings. All instruments are provided with shunting switches. When the engine is located in the wings the interrupter is mounted on a weather-proof casing attached to an engine-bearer, and the shunting switch is located on the instrument board.

The weight of any of the instruments is under ten ounces.

According to the manufacturers, various tests of the interrupter made by the Navy Department have shown in general the following results:

(a) As nearly as it has been possible to determine, the instrument will operate within one complete revolution of the engine following the propeller breakage, or within a time interval of one twenty-third of a second.

(b) It may be depended upon to do this every time that such a breakage occurs, as shown by tests in the air and on the ground.

(c) It will not interfere with the efficiency of the ignition system nor has it caused complications therein of any kind.

(d) The electrical resistance of the interrupter on Liberty engines has been determined by a representative of the Delco company as being less than 0.05 ohm, so the loss of potential in the primary circuit due to it is negligible.

Materials Used for Interrupter

Following are some particulars of materials employed in the construction of the interrupter. The latches and triggers are of hardened steel, heavily silver plated to minimize electrical resistance, to afford better contacts, and to prevent corrosion. Other contact parts are of hard brass, silver or nickel plated. All of the springs employed are of phosphor-bronze.

The electrical connections between the instrument base and its cover are by means of substantial screws which act not only as binding posts, but as attachment members holding the cover in place. These are all protected by castellated nuts and cotter pins. Molded Bakelite insulating parts are used. Owing to the extended development and tests involved the instrument did not get into quantity production until December, 1918.

German Giant Airplanes

A FIVE-ENGINED German bomber was brought down near Talmas on Aug. 10, but unfortunately, owing to the explosion of one of its bombs, the machine was damaged beyond hope of reconstruction. Some of its components have been recovered, and of these, the principal item of interest is the gear box, which is used for all five engines, each of which is a 300-hp. Maybach of the standard 6-cylinder vertical type.

The power plants are arranged as follows: In the nose of the machine is one engine driving a tractor screw. On each side of the fuselage, supported by the wings, is a long pair of engine bearers carrying two engines apiece, which drive tractor and pusher screws. The use of the gear box and driving shafts necessitates the employment of a fly-wheel on the engine, to which is added the female portion of a flexible coupling of the type already described. Whereas the gear box in the 4-engined giant is of a somewhat crude type, employing external driving shafts between the gear box and the engine, in the 5-engined machine the gear box design is considerably improved. The casing consists of a massive aluminum casting provided with four feet, which are bolted to the engine bearers.

Two kinds of gear boxes are employed in these "giants." These differ only in over-all dimensions and the length of the propeller shaft. The larger type is used for the pusher screw in order to obviate the necessity of cutting a slice out of the trailing edge of the main planes. All the gear boxes were very badly damaged except one of the longer type, but it would appear that the shorter design is very similar in appearance. In each case the gear reduction is 21:41. Plain spur pinions are used having a pitch of 22 mm. and a width across the teeth of 75 mm. The diameter of the smaller of the driving pinions is 162.5 mm., and that of the larger pinion 282 mm.

The overall dimensions of the long gear box are as follows: Length, 1025 mm.; breadth, 675 mm.; height, 535 mm. The driving pinion runs on two large diameter roller bearings carried in gun-metal housings supported in the inner end of the gear box. This part is split vertically, and united by the usual transverse bolts. The usual oil-thrower rings of helical type are fitted. At its outer end the pinion shaft terminates in a ring of serrations which engage with serrations provided in the male portion of the flexible coupling, these two parts being held together with bolts and clamping plates.

Truck and Tractor Engine Governors*

Function of the Governor—Various Types Employed, Their Advantages and Disadvantages—Points on Governor and Throttle Design

By R. B. Shoop
Mechanical Engineer, Minneapolis

THE function of a governor is to hold the speed of an engine between predetermined limits under all conditions of operation, from no load to full load.

The history of governors is very closely related to that of the steam engine, and our present day governors are very largely adaptations or improvements of the steam engine governor. James Watt discovered the necessity of some means to regulate the speed of his ponderous, slow moving engine and used the centrifugal type, as shown in Fig. 1.

Tradition has it that the first governor was the result of a boy's desire to play. The old engines had a cord attached to the throttle valve and a boy was employed to watch the speed of the engine and pull the cord when more steam was required. One day this boy yielded to his desire to play and tied two apples to the cord. The scheme worked and the present day governor was born, and some of the present governors, in action, closely resemble that "two-apple" governor.

Classification of Governors

Engine governors can be divided into three classes, as follows:

1—Hit and miss.
2—Throttling.
3—Ignition timing.

In practice, the third class is largely manual in operation, except where mechanical means are provided in the magneto to vary the time of the explosion. This class can be omitted from our discussion.

The hit and miss type is now obsolete in truck and tractor work. This type of governor acted on a pawl or "pick blade," which in turn held the exhaust valve open or the fuel valve closed, allowing a charge of pure air to enter the cylinder, instead of a charge of gas. The throttling governor is now universally used, as modern design has improved the economy of this type to such an extent that the better regulation more than offsets the possible saving in fuel and does away with the trappy devices and irregular explosions of the hit and miss governor.

Both the hit and miss and the throttling mechanical governor may be of one or the other of three types or a combination of two of them, viz.:

1—Centrifugal.
2—Inertia.
3—Pendulum.

The first two will be treated later. The pendulum governor is described by its name and is used largely on the hit and miss type.

Electro-Magnetic Type

The past year has brought us a new type, which we are all watching with deep interest, the electric governor. This device combines the governor, ignition, lighting and starting generator, coil and box, distributor and controller. The direct current generator is a 4 pole shunt wound type. The housing is mounted on trunnion bearings, which allow the generator to turn through an arc of 30 deg. The trunnion bearing shaft is brought through the generator housing and a lever is placed on the outer end. This lever is connected to the throttle valve. The revolving armature produces a magnetic drag on the field frame and causes it to rock on its axis. When the controller is placed in any given position the corresponding speed will be maintained, for if the engine speeds up due to decrease in load, the magnetic drag of the armature on the field is increased, causing the field frame to turn in the direction of armature rotation and close the throttle. If the load is increased the magnetic drag is decreased, allowing the field frame to be turned by a spring, to which is attached a piston operating in a dashpot to prevent too rapid a movement of the arm controlling the throttle valve. A hand wheel on the control box indicates the speed at which the governor holds the engine. The speed range is from 400 to 1650 r.p.m., but the manufacturer will supply the proper speed ratio to hold the engine at any required speed. A starting motor can be used with this device.

Factors Affecting Design

There are a number of variable factors entering into the design of a governor: The work the engine is required to perform, allowable speed variation between no load and full load, size and type of intake control valve, flywheel inertia, vertical or horizontal arrangement, speed, the manufacturing and inspection facilities, and unfortunately, in some cases lack of sufficient space.

If an engine is to do such work as threshing and plowing where there is a sharp rise in the power curve, the weights, springs, rise of governor collar, etc., should be greater than on light work. The weights should be balanced and the springs calibrated so that there is no binding or unequal pressure of moving parts. All moving parts should be inclosed in an oil tight, dust-proof case and should run in an oil bath or vapor. Ball bearings should be used on the principal parts and especially for taking thrust. Some manufacturers even mount the throttle valve on ball bearings.

The main fault of governors, aside from inability to see the approaching hill or the extra bundles thrown into the separator, is the "hunting." This is due to the fact that where there is a change in load, the governor makes an effort to take care of it. The force necessary to start the parts moving is greater than that required to keep them moving, so the throttle overruns its position. This speeds or retards the motor and the reverse action is necessary to maintain an equilibrium. Larger weights with proper springs, proper fitting, balanced throttle valve and anti-friction bearings will all help to overcome this defect.

Mounting of Governor Valve

The best way to mount a governor valve, when separate from the governor proper, is in a cage, as shown in Figs. 6 and 7. This allows a proper correlation of parts without depending on the carbureter and also allows a change in carbureter without disturbing the governor parts.

The governor should be set to run the engine at maximum speed, with the carbureter valve open. The retarding should be done with the carbureter control valve or governor speed controlling device. It is unfortunate that corporal punishment has been revoked in most states, as this should be the penalty for the chap who monkeys with the governor.

In a centrifugal governor, the so-called Watt or flyball type, Fig. 1, we have two or more weights revolving about the center spindle and connected to a sliding sleeve, which is in turn connected to the throttle valve by means of a bell

*Read at the January meeting of the Minneapolis Section of the S. A. E.

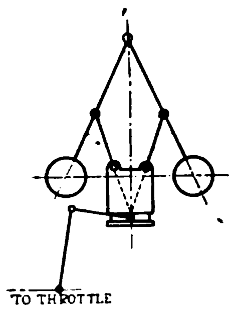


Fig. 1

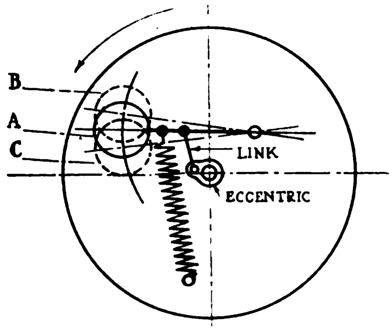

Fig. 2

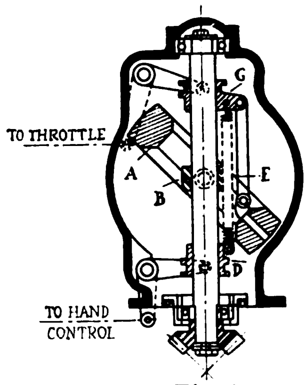

Fig. 3

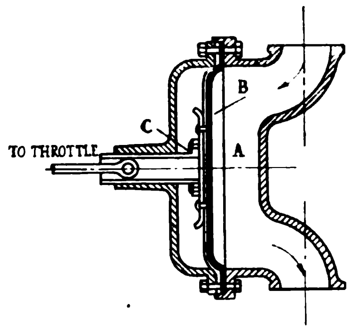

Fig. 4

crank or lever. The proper resistance to the centrifugal force of the balls is maintained by a loaded sleeve, or by springs. The loaded sleeve may be weighted by metal or actuated by a single spring mounted on the spindle or by double springs attached directly to the weights.

One type that is seldom, if ever, used on trucks and tractors is the inertia governor, the reason for its non-use being the difficulty encountered in properly mounting it in the limited space allowed and in balancing its revolving parts.

In a governor of this type the scope of action is a plane perpendicular to the axis of the shaft and the inertia of the weight *A* will make the governor more prompt in its action. If the governor is moving in the direction indicated by the arrow and the load is removed the motor speeds up. The inertia of the weights will hold it back and it will move to position *B*. If the load is suddenly applied, the inertia of *A* will cause it to surge forward to position *B*. This type of governon does not have the "hunting" tendency of the purely centrifugal type.

Adaptation of Marine Type

The ring governor, Fig. 3, was developed by one of the automobile companies and is an adaptation from marine steam engine practice. This is a centrifugal governor, in which the balls are replaced by a metal ring *A* pivoted to the collar *B*, which is mounted on and driven by the spindle. The ring *A* is connected to sliding collar *C*, which actuates the bell crank connected to the throttle by link *E*. There is a lower sliding collar *D* to which is attached the hand control linkage. This is attached to the upper collar *C* by means of a spring. This gives both automatic and manual control and is one form of speed regulator.

The hydraulic governor, Fig. 4, has been successfully used on at least one popular line of trucks. The device is interposed between the pump and motor. It consists of a water chamber *A*, with diaphragm *B* connected to plunger *C* which is attached to the throttle linkage. There is a speed and pressure constant for each motor speed and the diaphragm assumes the proper position for each speed, thus regulating the throttle valve.

Fig. 5 shows an intake governor, or a governor operated by the speed of incoming gases. The floating disk or piston *A*, which is calibrated for a velocity and butterfly friction, by means of side clearance and vertical holes, moves up and down according to the air speed and operates the butterfly *B* through the series of links. The moving parts are made of aluminum for lightness. This governor is interposed between the carbureter and the manifold of the engine.

Among other types of governors are the transmission governor, which regulates the engine speed from the top shaft of the transmission, and the road wheel governor, which is driven from the front wheel by a flexible shaft the same as a speedometer.

An investigation of governors is not complete without study of governor valves. The governor may be attached to the butterfly valve of the carbureter, but a separate valve cage is much better. This allows governor action unhampered by the extra linkage of the manual control. The governor should be set with the engine operating at maximum speed when the carbureter butterfly is wide open. The hand control is attached to the carbureter butterfly and is used for slowing down the engine.

Governor Valve

Fig. 6 shows a widely used type of governor valve. The butterfly is set at 60 deg., but may be set at 90 deg. with the axis, but the working arc is greater with more liability for "hunting," as the valve has to travel further from full closed to any desired area of opening. If the butterfly stem is placed in the center of the valve the pressure of incoming gases on the advancing side is greater than on the opposite side and imposes a greater load on the governor and linkage. This makes for uneven action, and the stem is often offset to

The Unmined Supply of Petroleum in the United States

(*Continued from page* 361)

Further recent geologic investigations in the field and the study of the results of testing and exploration, especially in the Rock Mountains and Gulf States, have furnished the basis for a more reliable recalculation of the estimates for a number of the regions. The conclusion reached is that the available oil in the ground at the end of 1918 approximates 6,740,000,000 bbl.

Available Oil Remaining in Ground, as Estimated by the U. S. Geological Survey (Bbl. of 42 Gal.)

Oil Fields	Marketed Production in 1917	Marketed Production in 1918 (Preliminary Estimate)	Total Marketed Production to End of 1918	Available Oil Left in Ground, January, 1919	Present Average Gasoline Extraction, Per Cent
Appalachian ...	24,932,205	25,300,000	1,221,737,000	550,000,000	28.0
Lima, Indiana..	3,670,293	3,100,000	448,404,000	40,000,000	28.0
Illinois	15,776,860	13,300,000	298,159,000	175,000,000	22.0
Mid-Continent..	144,043,596	139,600,000	990,573,000	1,725,000,000	24.0
North Texas ...	10,900,646	15,600,000	78,971,000	400,000,000	33.0
North Louisiana.	8,561,963	13,000,000	90,902,000	100,000,000	28.0
Gulf	24,342,879	21,700,000	303,954,000	750,000,000	01.5
Wyoming	8,978,680	12,370,000	39,793,000	400,000,000	40-50
California	93,877,549	101,300,000	1,114,000,000	2,250,000,000	12.0
Alaska, Colorado, Michigan, Montana, etc.	230,930	230,000	10,651,000	350,000,000	....
Total........	335,315,601	345,500,000	4,598,144,000	6,740,000,000	....

The new estimates, combined according to the commercial fields, are given in the accompanying table, in which for comparison and information are shown the marketed production for 1917 and the estimated output for 1918, as compiled by John D. Northrop, of the Geological Survey, in charge of statistics of petroleum and natural gas, and the approximate total production of petroleum in the United States to the end of 1918, also based on Geological Survey records. For the immediate convenience of the reader there is also included the percentages of average gasoline recovery from the oils of the different fields at the present time. For the later data the writer is indebted to Chester A. Naramore, of the Bureau of Mines, in which bureau the returns of gasoline recovery from the oil runs are compiled. The general characteristics of the various crude oils in the different fields are too well known to require discussion in this paper, and their especial qualities will be fully considered in those to follow. It will, however, be noted that the reserves of the heavy oils of California and the Gulf Coast are estimated at about 3,000,000,000 bbl. Probably such low-gasoline oils comprise more than one-half of the total reserves.

Later Estimates More Reliable

Those who have followed the history of petroleum in America and understand how much of our present-day oil-field development has taken place since Day made his estimates in 1908 and even since Arnold calculated the reserves in 1915 will appreciate the great advantages, mainly in the form of results of exploration and records of production, enjoyed by those who make computations now. However, with these circumstances in mind, we may, nevertheless, for comparison, compensate and bring to date the earlier estimates by deducting subsequent production to the end of 1918. The available oil in the ground at present would be according to these estimates, as follows:

Day (estimate in 1908), 5,402,000,000 to 19,902,000,000 bbl.

Arnold (estimate in 1915), 4,500,000,000 bbl.

Geological Survey (estimate in 1916), 6,647,000,000 bbl.

Geological survey (estimate in January, 1919), 6,740,000,000 bbl.

The recent estimate by the Geological Survey, as given above, and as differentiated by fields in the accompanying table, differs from that of 1916 mainly in a more conservative view as to prospects in Montana and recoveries along the Gulf Coast and in a more optimistic attitude toward Kansas and the States of little or no present production. As compared with the very conservative estimate formulated in the Geological Survey in 1917 they represent greater confidence in Wyoming, north Texas and Alaska and several of the minor States. In general, they are to be regarded as conservative, and there is little probability that the actual yield will fall short of the calculated amounts. They are, however, likely to be again revised in the near future, as the modes of occurrence of oil and gas in different regions become more fully understood, as exploration proceeds, and as the areas offering possibilities of oil discoveries are examined more in detail.

The reports of production of petroleum in the United States, as compiled by the Division of Mineral Resources of the Geological Survey, show that since 1858 approximately 4,598,000,000 bbl. of petroleum has been taken from the ground. This is more than two-thirds as much as the amount which, according to the latest estimate by the Geological Survey, remains available, and exceeds what would now be left according to Arnold. Further, the oil companies are now taking out over one-third of a billion barrels a year.

Relation of Production and Consumption

The situation as to petroleum production and the importance of the remaining oil resources of the United States are both graphically indicated by the curves in the accompanying figure. The most significant features here shown are the steep ascent of the consumption curve and the flattening, in 1918, of the curve of actual production in spite of the vigorous efforts of the oil companies to increase their war-time output even at the expense of their proved reserves. To fill the gap between our actual domestic production and the requirements of domestic consumption it has been necessary to reduce the oil in storage to the extent of 27,000,000 bbl. and to supplement this with a net importation of 31,000,000 bbl., chiefly from Mexico. The deficiency of our current production during 1918 has, therefore, amounted to 58,000,000 bbl., nearly half of which has been withdrawn from storage. That is to say, this country has to the extent of 27,000,000 bbl. of storage oil been "living on its hump," which is now reduced to about 123,000,000 bbl.

According to general expectations, barring disaster or shortage of supply, or much higher prices which might result from such shortage, the consumption curve is destined during the next year, and probably longer, to continue its present general trend beyond the 400,000,000-bbl. mark, which it nearly reached (397,000,000 bbl.) in 1918. On the other hand, whether the domestic production can be increased in volume to correspond to the consumption remains to be seen. Glenn pools and Cushings may await discovery, but the strike of a Glenn pool such as produced the bulge in the storage curve for 1907 and 1908, or of new Healdtons and Cushings, such as were largely responsible for the production swell of 1914-15, will make a less conspicuous wave in the greatly expanded and diffused production of to-day. Texas, the Osage country and Wyoming will furnish notable contributios, but so many fields are now running down that it will require numerous successive strikes of large magnitude to send the production curve so high that oil will go into storage without considerably increased importations. On the whole, even with prices stimulating the driller to greater efforts, it seems unlikely that the domestic production of petroleum can at best gain appreciably on the reasonably expected increase in consumption. It seems more probable that, unless consumption is restrained by high costs, the gap between consumption and production will continue to widen. In any event, this gap must be filled with oil from other sources. Further exhaustion of stocks in 1919 is a certainty that can be successfully minimized only by still larger importations.

The situation demands not only the prevention of waste, but the most economical and efficient use of our oil. Also, it warns operators to consider more thoughtfully and promptly the acquisition of foreign oil reserves. Mexico, to which the American public looks with optimistically hopeful eyes, probably contains less oil—perhaps very much

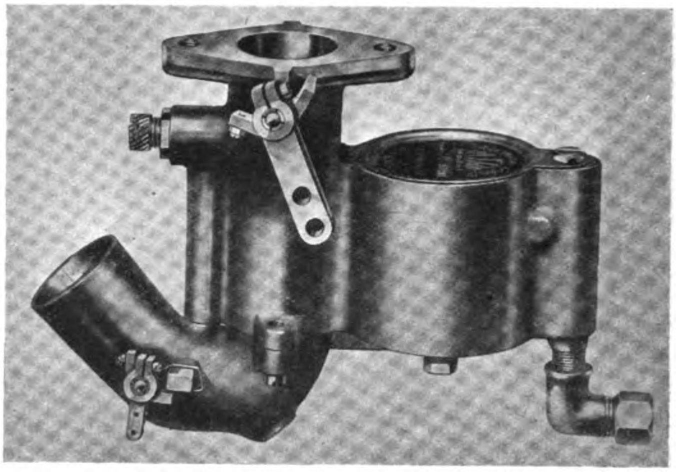
Sectional view through the Sunderman carbureter showing the floating venturi, mushroom jet and air bypass



The new Sunderman carbureter, showing throttle valve, choke valve, air bypass and gasoline connections

New Sunderman Carbureter Uses Floating Venturi

Employs Mushroom Jet and Air Bypass for Regulating Depression at Nozzle

THE Sunderman Corp., Newburgh, N. Y., has brought out a new carbureter which it is marketing under the name of the Nitro. It is a plain tube type, employing a floating venturi and a mushroom nozzle for compensating the ratio of air to gasoline. The nozzle is also relied upon to produce an atomizing effect so that the fuel is reduced to a fine fog before it is mixed with the air.

The floating venturi slides in the jet passage and is concentric with the jet. At idling speeds the float of the venturi is at the jet, while at high speeds it is considerably above the jet, as shown in the diagrammatic illustration herewith. When the venturi rests upon its seat at idling speeds, a very small air passage results which greatly increases the air velocity at the jet, increasing the suction and producing the relatively rich mixture required for idling.

Moderation of the suction on the jet is secured by an adjusting screw which controls an air bypass. This adjustment reduces the suction on the nozzle at lower speeds and consequently reduces the flow of fuel and at the same time prevents the venturi from rising too rapidly. When the throttle is open and the vacuum increased the venturi commences to rise on the air screen and draw away from the nozzle. This opens up the air passage around the nozzle, due to the tapered walls of the venturi, and compensates for correct ratios of air and gasoline. At higher speeds the venturi rises above the air passage, as shown in the diagrammatic illustration. This blocks the passage and puts it out of action, causing all the air to flow through the main passage.

It is claimed that this increases the volumetric efficiency of the engine by giving the maximum air passage. The venturi is a true streamline shape and consequently is designed to give practically no resistance to the free inflow of air while increasing the velocity at its narrow throat. The venturi at all times automatically centers itself on the air screen around the nozzle. It has ample clearance in the carbureter barrel for freedom of motion.

The mushroom nozzle has a calibrated hole drilled in the end of the jet tube to a size suitable for the particular requirements of the engine upon which the carbureter is installed. The jet feeds into the mushroom head and out through four small holes, spreading the gasoline by capillary action. Due to this spreading action it is claimed that the fuel is spread in a thin film to all sides of the under surface of the slot. Here the ascending air picks it off at right angles to its path. The Sunderman Corp. is preparing to turn out this new carbureter for regular equipment by car and truck manufacturers, and will also produce an aluminum model for Ford replacement.

Part II

A Discussion of Various Features of Design, with Reasons for Their Adoption —Performance of Planes Equipped with the Engine

By J. G. Vincent

FIG. 1 clearly indicates the general construction of the conventional type of seven-bearing crankshaft. This type was selected on account of comparatively large bore and stroke of the engine, which made it practically impossible to consider any less number of bearings. No counterweights were considered, because the engine is of the direct-drive type, and not intended to run over 1800 r.p.m. At this speed the main bearing pressures, due to centrifugal force, are not excessive. All main bearings, except the front one, are of the same length, which, of course, results in the bearing pressures being highest on the center bearing. Conservative designs would have dictated a longer center bearing, but as this would have lengthened the engine and added some weight, we decided against it, as calculations and experience indicated that it was not absolutely necessary. Although this center bearing actually showed more wear in service than any of the others, it was never a source of trouble, as the wear was not excessive. From my experience with these engines, I would make the same decision again under the same circumstances, but would lengthen the bearing about 50 per cent, if I were designing an engine for commercial aviation. In this connection I will also state that for a commercial aviation engine I would make all main bearing shells ¼ in. thick, instead of 3/16 in., as is the case in the Liberty.

The crankshaft main bearing journals are all 2⅝ in. in diameter and the crankpins 2⅜ in. The crankshaft cheeks, as originally designed, were the weakest point, and when we began to get into quantity production, small variations in material and heat-treatment occasionally resulted in a broken shaft; sometimes within a few hours and sometimes after from 50 to 100 hr. use. It was, of course, impossible to make the cheek any thicker, and it was, therefore, decided to widen them.

So far as I am aware, no crankshafts of the revised design were ever broken, with the exception of the occasional shaft that contained a flaw, and these usually let go before the engine had passed its manufacturer's test. It is my belief that the crankshaft as strengthened is an entirely practical and satisfactory design for this type and power of engine.

Connecting-Rods

The design of connecting-rods and connecting-rod big end bearings, as originally specified, were on the light side, and while the connecting-rods themselves would stand up indefinitely, if made out of the best material with the best heat-treatment, the least variation would result in trouble. It was, therefore, decided to thicken all sections about 1/32 in., and while this added weight to the engine, it made a thoroughly practical manufacturing proposition.

One of the sources of trouble with the original design was sharp corners under the connecting-rod bolt heads, and this was generously filleted in the redesign. The trouble with the connecting-rod bearings was that they were too thin, with the result that they went out of shape under heavy load, and the continual distortion would crack the babbitt. These bearings would not burn out nor break, but the babbitt would simply disintegrate, with the result that when the engine was taken down after 50-hr. use, the bearings would be in bad shape, and would all have to be replaced. This trouble was entirely overcome by increasing the thickness so that the thinnest portion under the straddle-rod forks is 9/32 in. thick.

The connecting-rods and connecting-rod big end bearings, as finally proved out and standardized, gave a uniformly satisfactory result, and I would not know how to improve them if called upon to do so at this time. We carried out a great many experiments at McCook Field with various kinds of V-type connecting-rods, including the so-called "Marine type," such as is used on the 300-hp. Hispano-Suiza, and the so-called "articulated type," such as is used on the Rolls-Royce. Both of these types can be made perfectly satisfactory, but we could not determine that they were any better than the so-called "straddle-rod type," as standardized for use on the Liberty. The connecting-rod piston-pin bushing, with its splash lubrication, proved entirely satisfactory, which seems to indicate that there is no necessity for carrying pressure oil to the piston pin.

The connecting-rod length to stroke ratio is 1.71 to 1. This proved satisfactory, but I would not recommend designing an aircraft engine with any lower ratio.

Pistons

The die-cast aluminum-alloy piston design, as originally laid down, proved very satisfactory, and was never changed. This piston design was originally dictated by Mr. Hall's experience, as he had proved by extensive experimental work the value of a very thick head and tapered piston wall increasing in thickness toward the top, in order to be as thick back of the piston rings as through the head. The purpose of this thick piston head and tapered wall is, of course, to provide for the proper transfer of heat from the piston head to the cylinder wall.

The piston pin is of the floating type, held in position by aluminum washers pressed into the piston at each side. This construction proved to be very satisfactory and prevented the usual trouble of cotter-pins and set screws dropping into the crankcase.

We had a little trouble at first with the pistons scoring, because they were too soft to work satisfactorily against the steel cylinder. This trouble was quickly cured by making the pistons harder and watching the heat treatment of the cylinders to get them of a uniform hardness, though still machinable.

The crowned head high compression piston gives a compression ratio of 5.4 to 1. The low-compression piston is flat on top but has the same bearing length as the high-compression type. The low-compression piston was used for all navy engines, as they work at comparatively low altitude, and the high-compression for all army engines, as they were intended for use principally at high altitude.

Propeller Hub

As originally designed, the propeller hub was intended to be put on the crankshaft permanently, as it was feared that a detachable hub would give trouble in an engine of so large power. This design, however, was contrary to foreign practice, and so much pressure was brought to bear in favor of the detachable hub that the design was changed before the engine was ordered into production.

*Paper read at the annual meeting of the S. A. E.

Fig. 1 shows the propeller hub as finally designed, including the propeller hub key running clear out to the rear end. The taper is 1 to 12. The propeller hub key as originally put into production was short, and did not extend within 1 in. of the rear end. This construction gave trouble, in that the hub would freeze on the shaft, making it hard to remove and impossible to replace without filing and lapping.

This trouble was largely overcome, and a practical result obtained by extending the key clear to the rear end of the hub and grinding the shaft and hub so that all the draw came at the rear end. By this I mean that the tapers were made so that they did not exactly match, and the front end of the shaft would be perhaps 0.001 in. loose with the rear end drawn up tight. This simply insured that the hub would be absolutely tight at its big or driving end.

The offset hub, as shown in Fig. 1, was really an afterthought to allow room for shutters in front of the radiator, but it proved more satisfactory than the conventional type, due, it is believed, to the reinforcing of the rear flange by the hub extension. The diameters of the propeller hub flanges and bolt circle, as well as the thickness of the propeller hub, proved entirely adequate for the horsepower output of the engine.

Crankcase

As shown in the illustrations, the crankcase is of the deep box-section type; the upper and lower halves being lapped together and firmly anchored to each other by numerous bolts around the flanges, as well as long through bolts on each side of all main bearings. The design of the individual steel cylinders made it possible to extend them down into the crankcase, thus greatly increasing the possible depth and strength of the crankcase, and at the same time making it possible to reduce the included angle between the two rows of cylinders to 45 deg. As clearly indicated, the main bearings are carried between the upper and lower halves. In my opinion, the design of this crankcase had a great deal to do with the satisfactory operation of the Liberty engine, and I know that no other type could be designed anywhere near as light and still stand up.

After the Liberty engine had been in production for some months a well-known English engine expert came to America, and in going over the design of the Liberty engine with me he asked where we got our information as to the design of the crankcase. After I explained its advantages he told me that they were just then beginning to realize the value of the box-section type of crankcase in England, and that experiments carried out recently had proved to them that this type with the bearings carried between halves is a very great improvement over any other design which they had used. The engine-bed flange design, including the number of bolts, form of ribbing, etc., has proved entirely satisfactory.

Cylinders

The individual cylinder design was, of course, originally selected on account of the necessity for a seven-bearing crankshaft, but while the design was being laid down it was recognized that the individual design was right for several other reasons. This design made it possible to machine pilots to extend into the crankcase, thus increasing the depth of the crankcase and making it possible to narrow up the angle without weakening the crankcase too much at the center or having the cylinder flanges overlap. The steel cylinders were selected for this make for more simple machining and easier application of the steel water-jacket. This design also makes for easy assembling and dismantling of the engine, and therefore facilitates manufacture as well as maintenance. It is very convenient to be able to remove a damaged cylinder quickly without disturbing the remainder of the engine and without removing it from the 'plane. In my opinion, the steel cylinder is the lightest that can be designed, and its construction provides for the best possible valve cooling. In spite of the fact that the Liberty valve is 2½ in. in diameter in the clear, it cools very satisfactorily, and I have seen any number of engines taken down after 100 hr. flying with the valves still in good, serviceable condition. Owing to the shape of the steel water-jacket around the spark plug, considerable difficulty was experienced in producing this stamping, but dies were finally devised which produced a perfect result with the minimum of scrap.

Manufacture of Hollow Forgings

One of the big manufacturing problems in connection with the steel cylinder was to secure hollow forgings of the proper material, which would provide for the minimum removal of material in machining. This job was submitted to two different companies, the Ford Motor Co., Detroit, and the J. G. Brill Co., Philadelphia. Both worked out a thoroughly satisfactory and economical forging. The Ford company worked out a process to make this forging from steel tubing, while the J. G. Brill Co. used a process to make the forgings from billets. One of the difficulties in producing this forging was the fact that its flange is located several inches from the lower end. It is my belief that both companies finally used the same process to produce this flange, consisting of an upsetting operation, with the bore properly reinforced by a pilot.

The valve port cages are machined from separate forgings and welded on, the camshaft housing support bosses being machined as an integral part of these ports. The design is such as to provide for water-cooling for almost the entire length of the exhaust valve stem guide. Proper welding on of the steel jackets proved to be simply a matter of practice to get a good job, and girls were used largely for performing this operation. The only trouble that I have ever heard of in connection with these cylinders was an occasional leak in the water-jackets, which usually occurred at the top of the jacket. This trouble would not occur frequently enough to be of any great importance, but we carried on extensive experimental work, in an endeavor to find out what caused it, and came to the conclusion that it was caused by the flexing of the jacket, due to slight distortion of the cylinder head, under the force of the explosion. If this is a correct deduction there are two ways the trouble could be cured, one being to put a positive tie between the valve ports, and the other to thicken the cylinder head, say 1/16 in.

Camshaft Housing

The camshaft and housing assembly, as well as the valve rocker arms, are clearly shown in Fig. 2. This construction proved to be very satisfactory, as it is positive in operation, practically never gives trouble, is quite easy to assemble and disassemble, and throws very little oil. This is the only type of valve operating mechanism that has given real satisfaction in connection with V-type engines having steel cylinders and exposed valve springs. It is, of course, a much simpler problem to work out a valve-operating mechanism for cast-in-block engines like the Hispano-Suiza, where the entire valve mechanism is covered, and therefore oil-tight.

The arrangement of the driving gears is very clearly indicated in Fig. 1. This arrangement of gearing proved very satisfactory after we had overcome the initial troubles due to bad design, such as lack of proper fillets, metal being cut down too thin under the teeth, etc. During the early manufacture there was a tendency to make these gears too hard.

Some trouble was experienced with the meshing of the bevel gears in the early stages of manufacture, due to the expansion of the crankcase and crankshaft under heat. This trouble was finally overcome by working out the proper clearances and then shimming to that clearance.

The recent Mercedes engines contained a very great improvement, however, at this point. The bevel gear is splined on the crankshaft with a sliding fit, and a separate thrust is provided to locate the gear and determine its mesh. This does away with all variations due to expansion and contraction, and is therefore a great improvement.

Before we had extensive experience with these engines it was predicted that we would have a great deal of trouble from breakage due to crankshaft vibration. I know that the Rolls-Royce company did have serious trouble of this kind, and were forced to put in a compensating spring drive on the crankshaft gear. I believe that we would have had the same trouble with the Liberty had the cylinders been placed at an angle of 60 deg., but due to the 45-deg. angle the periodic vibration seems to be broken up to a marked degree.

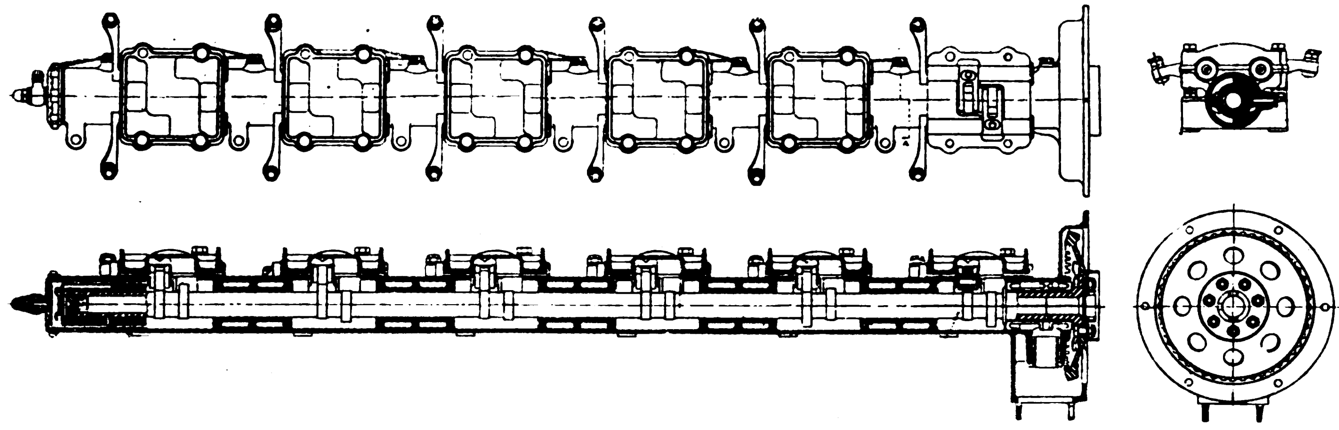

Fig. 2—Plan and vertical section through cam housing

This could, of course, only be proved by building a sample 60-deg. Liberty, but I firmly believe that the 45 deg. allowed us to get by at this point with the simple, light construction.

Lubrication

The double-deck oil pump and pressed-in oil manifolds are shown in Fig. 1. The crankcase is of the dry type, all oil being returned to an outside tank, cooled, and then pumped to the bearings under pressure.

As originally designed, the so-called scupper type of oiling system was provided for the connecting-rod big end bearings. With this system the crank cheeks are not drilled, but part of the oil which works out of the ends of the main bearings is caught by scuppers or scoops and conducted into the large drilled hole through the crank-pin. This system has some very desirable features, among which are simplicity and superior oil economy, and under ordinary conditions it works extremely well, but unfortunately it has one serious drawback. Due to the fact that the large holes through the crank-pins are open, all the oil drains out when the engine is stopped, except in those crank-pins which are near the bottom. This does not make much difference in warm weather, as the oil will quickly flow to the ends of the main bearings, and be caught by the scuppers, when the engine is started, but under cold weather conditions trouble results, and bearings are liable to be burned out, particularly if the throttle is opened quickly after starting. Since this scupper feed oil system had been criticized by foreign engineers, we wasted no time in changing over to the full pressure feed system as soon as the first trouble showed up. Comparatively few engines were manufactured with the scupper feed, and so far as possible all light crankshaft scupper fed engines were kept in this country.

Full Pressure Substituted for Scupper System

After adopting the full pressure feed system no further lubrication trouble was encountered, with the exception of over-oiling of the cylinder and fouling of plugs at high altitudes. This trouble was very largely overcome by drilling a hole in the by-pass valve of such a size as to lower the oil pressure to about 3 to 7 lb. under idling conditions, and still provide 30 to 40 lb. of oil pressure under full load. This device was entirely satisfactory, with the exception that it varied somewhat with different kinds of oil.

At the time the armistice was signed we were experimenting in the air with various kinds of devices inter-connected with the throttle to control the oil pressure positively. This is a comparatively easy thing to design, but we wanted to accomplish the result without making any changes in the basic parts of the Liberty engine. Although this device never got into production, I feel that the principle of positively controlling the oil pressure is correct and should be a part of any aircraft engine design.

Cooling System

The construction of the water pump is clearly shown in Fig. 1. One of the important features of this pump is the automatic spring take-up of the two stuffing boxes, one of which seals the oil in the engine and the other the water in the pump. This construction proved very satisfactory. From an installation point of view, the water-pump is located in a rather bad place, and experience seems to indicate that the best practical place to locate the water-pump is at the bottom of the crankcase near the rear end, in a vertical position, as on the Hispano-Suiza aircraft engine. Nothing which ever has to be got at should be located on the rear end of an aircraft engine, as it is often desirable to locate the engine just in front of a permanent bulkhead. To have located the water-pump as suggested in the Liberty engine it would, of course, have been necessary to have a different arrangement of the oil-pump. The Hispano-Suiza oil-pump is a very satisfactory arrangement, but I prefer that the oil-pump be located so that it can be got at from the bottom or one side of the crankcase, without disturbing the water-pump or any other accessory.

Rumors of Overheating Troubles

Many rumors have been circulated that the Liberty engine is hard to cool, but this is not and never was a fact. We did have two difficulties in connection with cooling the Liberty engine, one being the difficulty which we had in obtaining good tubular radiators, and the other the difficulty involved in working a 400-hp. radiator into the design of a plane which had originally been laid out for 240 hp. We were handicapped by not knowing just how much radiation to provide, as there is a great deal of difference in cooling an engine on the ground and cooling it at 10,000 or 15,000 ft.

We finally adopted the British practice on radiators, as follows: All radiators to be of the tubular type with the ratio between the inside diameter of the tube and its length 1 to 12 desired, and from 1 to 10 to 1 to 14 permissible; the size of the radiator to be determined by the horsepower output on the climb, 0.7 sq. ft. of wetted surface per hp. output being the desired figure. The area of the wetted surface is determined by calculating the outside surface of the tubes, nothing being deducted for the short space taken up at each end by solder:

$$\frac{\pi d l n}{144p} = 0.7$$

Where d = outside diameter of tube in inches
l = length of the tube in inches
n = the number of tubes
p = horsepower on the climb.

This formula has been extensively used, and a radiator designed in accordance with it will give perfect satisfaction on any well-designed aircraft engine, providing the radiator is well made, properly located, and the air flow through it is not badly choked by obstructions.

For military work, shutters must be provided in front of the radiator, so that the pilot can close off the cold air and regulate the temperatures at high altitudes, particularly in cold weather when gliding.

In Fig. 1 the arrangement of the ignition generator is shown, as well as the ignition heads of the Liberty generator type of ignition. The small 10-amp.-hr. battery used in connection with this system can be located in any convenient place about the plane, and the double ignition switch is, of

course, located at a convenient point on the instrument board.

At the time the Liberty engine was designed, so far as we knew, no reliable light-weight twelve-cylinder magnetos were in existence, and we did not want to follow the foreign practice of using four six-cylinder magnetos, not only on account of the weight of the magnetos but also on account of the weight and complications of the necessary drives. Mr. Hall and I have both had extensive experience with the generator type of ignition on aviation engines, and knowing that a light-weight reliable outfit could be secured, we deliberately incorporated it in the design, although we anticipated that we would meet with stubborn resistance from people who had not had experience with this type of ignition. The design, as originally laid down for this engine, proved to be exceedingly satisfactory, and very few changes were made during the early experimental stages.

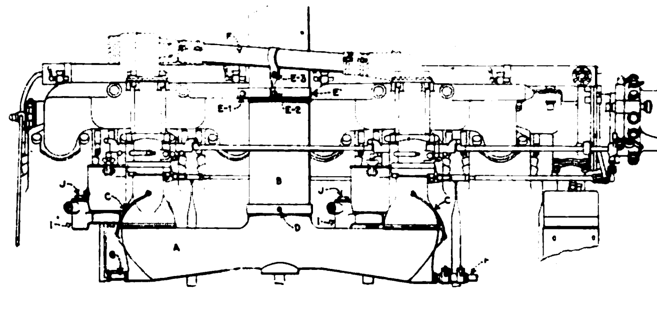

Fig. 4—Longitudinal elevation showing revised carbureter arrangement

Ignition Distributor Head

As indicated in the drawings, an ignition distributor head, complete with coil, is located at the rear end of each camshaft housing; each one of these heads is so cross wired as to make it possible to secure ignition in twelve cylinders on either head. thus providing a complete double system.

One of the very desirable features of the Liberty engine which is directly traceable to its ignition, is the easy starting, it being necessary to pull the engine over only very slowly to start it.

My experience would indicate that with a large-bore engine it is much better to start it by pulling it over slowly than on the spark with the starting magneto or vibrator. I believe this is due to the fact that to start on the spark it is necessary to have the mixture just right and on the rich side, and where several attempts are made to start from the spark, excess gasoline often accumulates in the cylinders and cuts the oil off the pistons, due to the large clearances. This is apt to result in scored cylinders.

I think the principal objection to the Liberty ignition system is the location of the ignition heads. They were, of course, placed in their present position to obtain simplicity and light weight, but in some installations they are in the way of a permanent bulkhead, and would be better located if placed at the side. It would, of course, add something to the weight to place them anywhere else, and this is a factor which would have to be taken into consideration. Since the Liberty engine was designed, some very excellent twelve-cylinder magnetos have been developed, and it is entirely possible that in laying out a new design at the present time a magneto installation might be provided which would be just as light and just as reliable as the generator type used on the Liberty. This is a matter which would have to be proved by actual design and exhaustive experimental work.

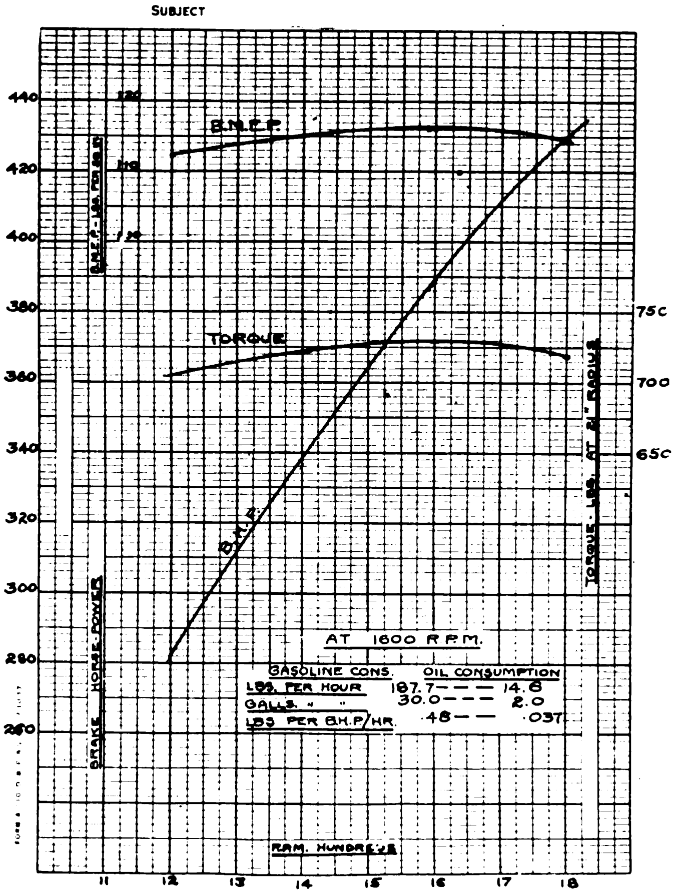

Fig. 3—Performance curves of well worked in twelve-cylinder Liberty engine

Carburetion

At the time the Liberty engine was designed, the only proved-out aircraft carbureter available in this country was the old-style single venturi Zenith, and, although we knew that this carbureter would not be entirely satisfactory, we had to specify it until such time as we could get definite information on something better.

Fig. 1 illustrates the arrangement of the Zenith carbureter, the intake header and water outlet arrangements. It will be noted that four intake headers are used, each serving three cylinders. It will also be noted that hot water is taken out of the top of the cylinders into water-jackets on top of the intake headers and piped from there to the radiator inlet. This arrangement of intake header proved very satisfactory, and resulted in very good distribution at all altitudes. It will be noted that the throttle valves in the carbureter were arranged fore and aft, instead of crosswise, to prevent interfering with the distribution under throttled conditions. This arrangement proved very satisfactory. The altitude adjustment originally provided on these carbureters had very little effect on the mixture, and was, therefore, unsatisfactory.

No strainers were provided in the original carbureter design, as it was thought that a strainer could be provided in a more accessible place. Experience proved this idea to be wrong, as small particles from the rubber hose connections would work into the carbureter and block the jets. This was particularly annoying, as the carbureters are located in an inaccessible place, and it was a considerable job to remove the jets and clean them out.

It will be noted from the drawings that individual air scoops were fitted to each carbureter, and that no provision was made for carrying these intakes outside the bonnet. Although these scoops were drained overboard the drain was only effective with the plane level or climbing, and a flooding carbureter on the glide would spill gasoline over the engine. If backfire occurred after this had happened, the plane might be set on fire. As soon as the engines were received overseas where they had had experience with fires, various modifications were promptly made to reduce the fire hazard, before the planes were flown, and we were requested to change the design as quickly as possible, to overcome this trouble.

While making a change to reduce the fire hazard, we decided to also alter the altitude control and provide screens at the carbureter and beyond all hose connections. Figs. 4 and 5 show the revised construction, which it was intended

should be in all production Jan. 1, 1919. The change in the altitude adjustment consisted simply in some rearrangements of the passages, and the construction, as finally worked out, was so simple as to make it possible to make this change in the field. To provide for a screen, a small aluminum casting *I*, Fig. 4, was provided, and arranged so that it would screw on to the old carbureter. This casting was provided with a nipple to receive the gasoline hose connection, and the screen was easily removable by taking off the nut *J*.

Fire Hazards Reduced

To prevent the possibility of fire, the individual air intakes were removed from the carbureter, as well as their retaining springs, and a single long intake *A* was provided and held on by spring bails *C*. This intake was machined at its center to receive a large single intake pipe *B* extending up through the center of the engine and out through the bonnet. The top end of this pipe was cut off at an angle of 25 deg. A dowel *D* engaged a slot in the intake pipe *B* and prevented it from turning. A clamp band *E* and *E* was arranged to anchor the intake pipe *B* to suitable cap screws already existing in the intake headers. The fragmentary plan view, Fig. 5, shows this rearrangement and the way it is necessary to bend the water outlet pipe to permit the installation of the new intake pipe *B*. The intake header *A* is provided with nipples *G* at each end, so that overflow pipes may be attached and carried outside the fuselage. It is obvious that this provides for the complete draining away of all stray gasoline, whether the plane is climbing, diving or flying level. This new arrangement of altitude control, carbureter screen and intake pipe has been extensively tested out in the air, and has proved to be exceedingly satisfactory.

The revised altitude control was worked out first and went into production in the early summer of 1918, and it is my understanding that all engines were equipped with this improved altitude control before being used at the front. Vague rumors to the effect that the Liberty engine has excessive gasoline consumption have been pretty generally circulated, and this, of course, if true, would be serious. It is obvious that all other things being equal, the gasoline consumption of the engine will be in proportion to the horsepower developed. All well-known aircraft engines at the present time have about the same gasoline consumption per horsepower hour. This runs from 0.48 to 0.56 lb. per b.hp.-hr., depending on conditions. In this respect the Liberty engine is no better, and no worse, than other well-known designs.

Gasoline Consumption

Running wide open near sea level, the Liberty engine will develop 400 to 420 hp. and granting that it develops the average, that is, 410 hp., and that the average service conditions maintain, it will probably have a gasoline consumption of 0.52 lb. per b.hp.-hr. Under these conditions it would burn 213.2 lb., or approximately 35½ gal. per hr. The same engine flying wide open at 15,000 ft. would be developing approximately 295 hp. and if the altitude adjustment was properly used, the gasoline consumption would be reduced in approximately the same ratio. This would bring the consumption down to 153 lb., or roughly 25½ gal. per hr. As a matter of fact, however, the general practice is to throttle down, except for short periods of time when it is desired to obtain maximum speed. Where a plane is capable of making 120 miles per hr. at 15,000 ft. altitude, it is good practice to throttle down to between 90 and 100 miles, thus enormously reducing the horsepower and gasoline consumption per hour, without seriously affecting the distance traveled. We know from practice that with a Liberty twelve mounted in a DeHaviland Four or Nine plane, we can average about 100 miles per hr. in cross-country flying at 15,000 ft. on 20 to 22 gal. of gasoline per hr. Throttling down still more, will further reduce the gasoline consumption, and it is possible to fly a DeHaviland Liberty-equipped plane at about 75 miles per hr. on 17 gal. of gasoline per hr.

Fig. 3 gives absolutely accurate data as to gasoline and oil consumption of Liberty engines running wide open at 1600 r.p.m. near sea level.

Radical Carbureter Design Evolved

A rather radical carbureter design, which was worked out for the Liberty twelve, while only used experimentally, gave some very promising results. Fig. 6 shows this experimental carbureter and intake header arrangement, and Fig. 7 is a fragmentary plan view showing the same arrangement. Fig. 8 is a diagrammatic sectional drawing showing the principal parts of the experimental carbureter. It will be noted that two carbureters are shown, as in the standard Liberty, but they are what might be called an inverted type. Without going into detail as to the construction of this carbureter, it will be noted that the double venturi arrangement, which has been highly developed during the war, makes this construction possible. The reason for this is clearly shown in Fig. 8. It will be noted that this type of carbureter cannot flood into the engine, as would be the case in the ordinary type of carbureter turned upside down. In Fig. 8, *D* is the needle-valve float, *Y* the drain compartment connected to an overflow pipe, *K* the altitude valve, *F* the jet, *N* the compensator well, *M* the compensator feed holes, *I* the compensator, *L* the idling mixture passage, *O* the passage to the secondary choke, and *P* the secondary choke. This arrangement is very desirable for airplane use, as it provides short separate intakes from each carbureter that project directly out through the bonnet and make fire from backfire impossible. Another important advantage of this arrangement is the matter of accessibility, as the carbureters are right up on top of the engine, where all connections and adjustments can easily be gotten at, and it leaves the *V* between the cylinders absolutely clear for machine-gun installation.

It is obvious that this type of carbureter requires a different kind of intake header, and as designed for the experimental job there were rights and lefts, as shown by *A* and *B*. This construction made it necessary to change the water outlet headers, and provide a separate outlet manifold *R* for each line of cylinders. On account of the gas impinging against the bottom of the header in this construction it is necessary to place the water-jackets on the bottom of the intake headers, and to get hot water into these jackets a connection was made at the rear end through the water outlet manifold *R* by the pipe *N* and hose *P*-6. The jackets were connected at the center by the nipples *M* and hose *P*-7. At the front end the jackets were connected to the water manifold *R* by the nipple *M*, hose *P*-1 and pipe *O*. This pipe *O* was arranged to extend inside and then turn forward with the flow to form an ejector and thereby induce some of the hot water to flow through the jackets. This construction worked out very satisfactorily, and the intake header seemed

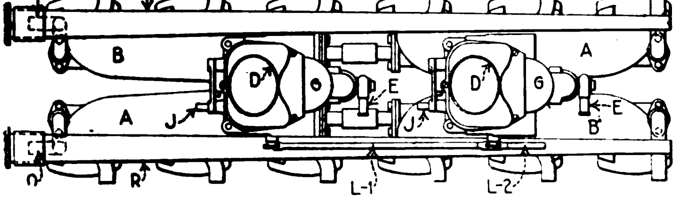

Fig. 5—Plan view of revised intake header arrangement

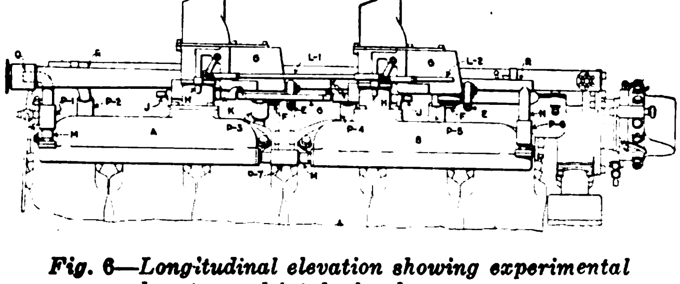

Fig. 6—Longitudinal elevation showing experimental carbureter and intake header arrangement

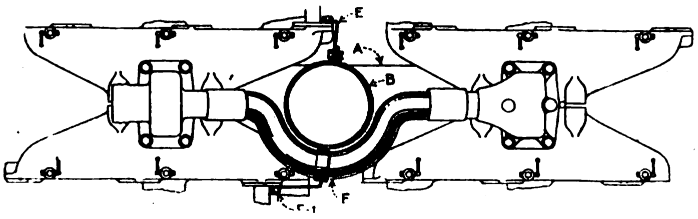

Fig. 7—Fragmentary plan view showing experimental carbureter and intake header arrangement

to keep just as hot as in the standard Liberty construction.

As stated above, this whole inverted carbureter arrangement was treated as a purely experimental proposition, as it was recognized that it would be impossible to put it into production owing to the fact that absolutely new carbureters would require new tooling up as well as many other small parts. I believe, however, that all those who have tested this arrangement believe it to be the best possible installation for the Liberty engine. This carbureter arrangement has every advantage of all such arrangements that I know of, that is, that it does not provide for gravity feed.

Angle Between Cylinders

The Liberty engine has been criticised on account of its cylinders having been set in an inclined angle of 45 deg. All experts in engine design know that a six-cylinder engine is perfectly balanced. Two six-cylinder engines hooked to the same crankshaft are also perfectly balanced at any angle, except as to impulse frequency. Before designing the Liberty engine I had experimented extensively with various angles of cylinders, and knew that the 45-deg. arrangement would not be noticeable, so far as lack of smooth running was concerned, and that it had distinct advantages, not only in that it reduced head resistance, but also that it reduced synchronous vibration of the crankshaft due to the breaking up of the evenly spaced impulses.

The cover over the oil pump in the Liberty engine is held on by a spring bail, which, while readily detachable, cannot jar loose and come off. This is a well-known mechanical device which has been used for years for exactly similar purposes. This little device, however, has been the subject of widely circulated criticism, and I do not know how much it has cost the Government to investigate persistent criticisms on this device sent in by irresponsible people.

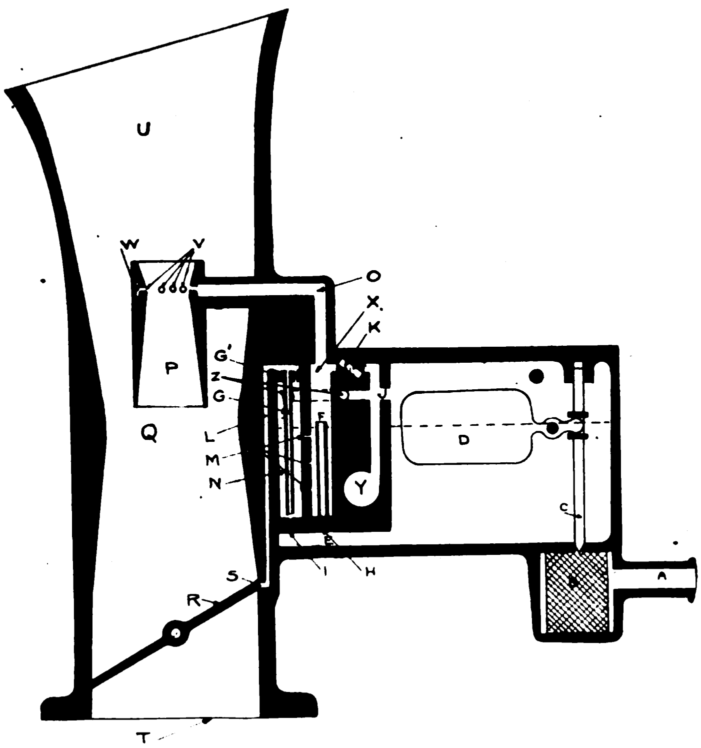

Fig. 8—Sectional diagram of experimental carbureter

Weight Per Horsepower

I believe that it is pretty generally known that the Liberty engine weighs approximately 2 lb. per hp. By using still better materials, making the engine considerably harder to manufacture, and lowering the factor of safety, which is pretty high, it would be possible to bring the weight down to about 1.8 lb. per hp. This would greatly increase production troubles, would require more skilled mechanics to keep it in working order, and would, therefore, in my opinion, be an inadvisable move.

I believe that one of the outstanding features of the Liberty engine, as it is now being manufactured, is its reliability. I have flown the Liberty engine thousands of miles cross-country and have yet to make a forced landing. This reliability has, of course, been developed by extensive experimental work in the air and close attention to details of manufacture and inspection.

Reports have been promiscuously circulated that while the Liberty engine has been proved to be good for large bombing machines it cannot be used in a small, fast fighting or chasse machine. It was never intended that the Liberty twelve should be put in a small, single-seated chasse machine, and that is the reason the Liberty eight was developed. It was our original plan to put the Liberty eight into production and use it for just such small machines, but when our program was finally made up, based on advice from abroad, it did not include a single-seated chasse machine, and for that reason the eight cylinder was not put into production at the time. Some four or five months ago it was decided that we should develop a single-seated chasse machine in this country, and the Liberty eight was promptly brought out and ordered into production. Airplane designers generally agreed that the Liberty eight-cylinder engine, developing as it does 300 hp. and weighing approximately 600 lb., will make a very satisfactory powerplant for a plane of this type.

Air Performance

Owing to the fact that the performance of an airplane must be measured in the air, it is a rather involved matter to make a full flight test, requiring, as it does, a number of special instruments, a well qualified pilot, and proper technical experts to make the necessary corrections for temperature, air density, etc., after the readings have been secured. When we first started making full-flight tests in this country we did not have the proper equipment, and a number of tests were made and reported which were not on a comparative basis with similar tests of allied planes made in Europe. Quite naturally, this has led to a misunderstanding, and it has been claimed that the DeHaviland-Four plane equipped with the Liberty engine, is not as good as allied planes equipped with engines of much less horsepower.

To throw some light on this subject I am giving below a few comparative figures covering foreign planes. They give average performance of three well-known planes, namely: the French Salsom 270 hp., English DH-4, using the Siddeley 240-hp. engine, and the Italian Pomilio E, using the Fiat 240-hp. The USDH-4 is, of course, equipped with the Liberty twelve. The figures on allied planes were secured from official technical reports from abroad and figures on the USDH-4 were taken from tests made by the Technical Section of the Department of Military Aeronautics and the Engineering Division of the Bureau of Aircraft Production.

OBSERVATION PLANE

	Average Foreign	DH-4
Power, hp.	266.6	400
Speed at sea level, miles per hr.	116.8	128
Climb to 10,000 ft.	9¼ min.	7½ min.
Ceiling, ft.	20,267	21,000
Endurance (Cruising)	3½ hr.	4⅓ hr.

DAY BOMBER

Power, hp.	266.6	400
Speed at sea level, miles per hr.	110.5	118
Climb to 10,000 ft.	11¼ min.	11 min.
Ceiling, ft.	16,000	17,500
Endurance (Cruising)	3½ hr.	4 hr.
Bomb load	423 lb.	223 lb.

RADIUS OF ACTION, MILES

British DH-9	256
British DH-4	244
Breguet	151
USDH-4	310

In the above comparison it will be noted that the USDH-4 equipped with the Liberty twelve shows up well in all cases except the load of bombs carried as a day bomber. This machine was originally designed for a 240-hp. engine, and when equipped with a slightly heavier 400-hp. Liberty, plus the necessary gasoline for a larger engine, its carrying capacity is naturally cut down. It was to take care of this work that the USD-9-A was being put into production just as the armistice was signed. This machine has 500 sq. ft. of surface and carries 500 lb. of bombs with practically the same performance as the USDH-4. In addition to the USD-9-A, the following planes were being put into production at the time the armistice was signed:

VE-7 advanced training machine, equipped with 150-hp. Hispano-Suiza.

Le Pere two-seated fighting machine, equipped with the Liberty-twelve.

Glenn Martin day or night bombing machine, equipped with two Liberty-twelves.

U. S. Bristol fighting machine, equipped with the Liberty-eight.

Many other new types of planes were in the experimental state, including several designs of single-seated fighting machines around the 300-hp. Hispano and Liberty eight.

The Unmined Supply of Petroleum in the United States

(*Continued from page* 376)

less—than remains in the ground in the United States.

How long the commercial production of natural petroleum will continue in this country is a question whose answer is no less speculative than the quantitative estimates. After the production peak is passed, be it one year or seven, the annual output of natural oil will decline gradually for a long time. Oil wells will be producing at least 75 years hence. The pools cannot all be so soon discovered; the oil cannot immediately be gotten out of the ground. The discovery of deep sands is likely to give new life to many old or even abandoned fields. Pools will be found after prolonged search and repeated wildcatting in old as well as new regions, and this is probably especially true of the Gulf Coast, where, unless geologic discovery and consequent new methods of search, come to the aid of the driller, it may be 75 years before some of the productive salt domes are revealed.

The most significant feature of the prospect, however, is the probability that, although an estimated two-thirds of our reserve is still in the ground, with an annual drain of one-third of a billion barrels, the peak of production will soon be passed—possibly within three years. The date when the peak will be reached is a matter of individual opinion, in which predictions have wide range. There are many well-informed geologists and engineers who believe the peak in the production of natural petroleum in this country will be reached by 1921 and who present impressive evidence that it may come even before 1920.

Development of Oil Shale

In her deposit of oil shale the United States has an anchor to windward. Oil shale is a richly bituminous shale, some of it approaching cannel in character, interbedded, like coal, in series of shales, sandstones and limestones. The most extensive and valuable deposits known in America if not in the whole world are in northeastern Colorado, northeastern Utah and southwestern Wyoming, mainly in what is known as the Uinta Basin. Rich beds of oil shale also occur in very limited areas in northeastern Nevada. Minor deposits, more conveniently located but for the most part leaner and less promising, are found in the Mississippi Valley and the Appalachian States. D. E. Winchester* and A. R. Schultz, of the Geological Survey, have estimated that there are in Colorado, Utah, Wyoming and Nevada deposits of oil shale in thicknesses of 3 ft. or more, and capable of yielding 25 gal. or more of oil per ton, sufficient to produce at least 75,000,000,000 bbl. of oil.

The oil is generated through the destructive distillation of the shale, and its character and composition depend largely on the processes employed. Rough dry or steam distillation tests produce distillates — essentially heavy petroleums — carrying both paraffin and asphalt with considerable nitrogen and yielding gasoline in an average of about 12 per cent. These rough tests indicate that the gasoline obtainable by distillation of these shales, even by simple methods, far exceeds in amount all the petroleum yet produced in the United States and may equal the remaining natural oil.

*U. S. Geological Survey Bulletin No. 641-F. 1917; Bulletin No. 691-B. 1918.

Shale Oil Production Still Experimental

The production of oil from these shales is still in the experimental stage, in which various methods are being tested. Much doubtless depends on the processes devised and adopted. It is possible that initial commercial success may be determined as much by a study of methods and of the possible by-products and their values as by a further advance in oil prices. The technologic problems connected with the utilization of the oil shales are worthy of research by the best hydrocarbon engineers and chemists.

Shale oil is the most natural, satisfactory and ample substitute for petroleum, and it is likely to come into the market as the production curve of the natural oil glides downward beyond the peak, if not sooner. It must be borne in mind, however, that in spite of the probable very rapid growth of the shale-oil industry beginning with the day that shale oil is produced profitably on a commercial scale, it will require several years to construct and put into operation the enormous plants necessary to treat the millions of tons of shale which must be distilled in order to offset the waning production of natural oil, or fill a part of the gap between the production and consumption of petroleum in the United States.

Prevention of Dust on Concrete Floors

IN an article in the *Schweizerische Bauzeitung*, Albert Meyers gives the following method for attaining the above object. It consists in the use of a potash-water glass solution at 40 deg. Baumé in three to four parts of water. The solution is applied with a brush, after the floor has been thoroughly scoured with water and then allowed to dry. After the solution is applied the floor is rubbed over with a wet cloth, and the whole operation repeated. In this way it should be possible to harden the concrete surface considerably and thus prevent dust formation.

Life of Self-Luminous Preparations

MEASUREMENTS carried out by Meitner, extending over a period of seven years, show for six preparations an average life value of 1.905 years, which agree well with the results of other investigators. Measurements effected on an eleven-year-old mesothorium preparation showed the half-value period for mesothorium to be 6.7 years instead of 5.5, which figure had been assumed previously. For thorium, the half-value period was calculated indirectly at 2.37 x 1.10 years.—*Elektrotechnik und Maschinenbau.*

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries-The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Machine Tools at the Show

NOT the least interesting feature of the New York show was the machine tool section in the basement of the Garden. Three complete exhibits of metal working machines were installed, besides a number of exhibits of miscellaneous shop equipment.

The machine tool industry has been engaged to full capacity on equipment for war work production during the past two years. Like certain contingents of our Army, it has been mustered out, and it is now looking for peace-time outlets. And there is probably no branch of industry that offers better chances to the toolmakers than that of automotive equipment. Take, for instance, the tractor branch. Aside from munitions, this has been one of the fastest growing industries in the country during the past two years, having doubled its output each year. The tractor industry has reached the stage where large scale production is about to begin, and this will mean the purchase of a vast amount of shop equipment.

In the automobile and truck industry, while we cannot expect the same rapid growth as in the younger tractor industry, there are also excellent chances for the sale of shop equipment. It is the consensus of opinion among engineers and shop men that the next few years will see progress chiefly in production methods. Automobile design has reached a very high degree of development, and no very striking or radical changes are likely to occur. But with stability in design that firm stands the best chance of success which can produce at the lowest cost. It is on the improvement of production methods that the automobile makers will largely concentrate their efforts during the immediate future, and this will favorably affect the demand for machine tools and other shop equipment.

Tractor Results

ONE of the most striking facts brought out at the S. A. E. session was in relation to the high fuel consumption observed in the British tractor trials. Some four-bottom tractors are said to have used as much as 8 gal. of fuel to the acre. The average consumption as given in one of the papers presented at the meeting was a little over 5 gal.

This is so high in comparison to what we have been getting that it shows the possibility of wide variations. Results in this country seem to indicate that the kerosene consumption per acre may be readily held down to 2 gal. under normal conditions.

When comparing the cost of operating tractor-drawn and horse-drawn farm implements the comparison should not be made solely on the per hour or per mile basis, but should include also a consideration of the element of speed and the fact that the tractor can be utilized to do the work at the time it is required. There is a "best time" for each job to be done on a farm and the tractor is capable of performing these jobs so much faster than horse-drawn implements that each can be performed at its proper time.

As Mr. Kettering pointed out at the S. A. E. meeting, even if the tractor as a whole is a bad mechanical proposition, the farmer cannot afford to throw it out. The filled silo and the bigger farm yield are a direct result of the ability to use the tractor in the short working season. There will be a better return than with horse farming, even if all the rest of the year has to be spent in tuning up the tractor.

ELECTRIC starting and lighting equipment was almost unknown in Europe previous to the war. It will be next to impossible, however, to sell post-war models there without a complete electrical system. European electrical firms have had little opportunity during the war to develop such equipment and our manufacturers certainly should not miss the opportunity offered them of getting their products taken up abroad. Some of the largest foreign firms, like Fiat and De Dion, have developed their own starting and lighting sets, no doubt because the home market did not offer any suitable equipment.

S. A. E. Fuel Division Needed

A FUEL division is needed in the Society of Automotive Engineers. One could not come away from the winter meeting of the organization without that thought in mind. We have motor car, truck, tractor, airplane and motorboat divisions, but no division to look after automotive interests as regards the fundamental necessity for all the other divisions—fuel.

There should be a vice-president of the fuel division in the same way as there is a vice-president for the other divisions of the organization. He would be able to look after the work which must be done during the next 3 years in meeting the greatest problem which confronts the automotive industry to-day. The problem is a part of two industries, the refineries on one side and the factories which make apparatus using internal combustion engines on the other.

No point of contact has hitherto existed between these industries, and nobody offers a more logical meeting point than the S. A. E. It is a problem that neither industry can solve alone, and it cannot be solved at once. There doubtless must be a transition period where we are changing from one fuel to another. Perhaps certain phases of design must be altered in order to meet the characteristics of the fuel that the refiners would evolve. Perhaps it will be necessary to alter compressions, manifold arrangements, lubricating systems or other details. All these matters would have to be taken into consideration before reaching a conclusion.

It is no simple problem and it cannot be dismissed with the thought that it is only necessary arbitrarily to fix a gravity below that now in use to greatly augment the supply. From the fuel maker's standpoint that would probably settle the problem for a while to come, but from the standpoint of the automotive maker and user the problem would be far from solved.

The car owner wants to be able to start his car on a cold morning. He does not want to have to change the lubricating oil every 3 days as is necessary on some of the farm tractors burning kerosene. Even with the present gasoline the amount of gasoline that enters the crankcase is so large that the life of bearings is seriously menaced if the owner does not take the necessary precautions in regard to changing the lubricant.

Even with the increased gravity of the fuel the question would only be solved from the refiner's standpoint for a relatively short space of time, because the use of automotive apparatus is increasing so rapidly that the problem would soon overtake us again.

The matter is brought squarely back to the engineer and technician in the necessity of producing engines that are more thermally efficient. The average automobile running about the streets with partially closed throttle is getting about 5 per cent of propulsive value out of the engine. The best thermal efficiency in the present type of automobile engine under advantageous circumstances is somewhere around 20 per cent. It does not require any mathematics to prove that this is very wasteful. It would be in the province of the fuel division of the S. A. E. to follow through the development work that is necessary in raising the efficiency of our engines.

Doubling the thermal efficiency of the internal combustion engine is equivalent to doubling the supply of fuel. A car that is now getting 20 miles to the gallon of fuel would get 40 if the thermal efficiency of its engine were raised from the probable figure of 15 per cent up to the possible of 30 per cent. It is easy to realize what a vast increase in our fuel resources would result from an improvement of this nature.

Similarly the ramifications of the problem even reach the building of good roads. It has been found that the consumption of a car going over bad roads can double and even triple that of a car going over the improved roads. Such wide differences in fuel figures have been found in districts where poor roads exist and in those that have the good hard surface roads that, neglecting the matter of time, the roads would be a true economic saving from the fuel standpoint alone.

All of this would be under the control of the vice-president of the fuel division or of the committee having this phase of the work in charge. There is no more vital work that can be undertaken than this. Every branch of the automotive industry is based solely and only upon the internal combustion engine. The internal combustion engine cannot exist without a suitable economical fuel. The present fuel will have to advance radically in price within the next 3 years under present conditions of its use. Now is the time to start work, before we have a real crisis.

Latest News of the

Airplane Show Space Allotted

Fourteen Makers of Planes and Engines and 32 Makers of Accessories Now Listed

NEW YORK, Feb. 11—Plans for the forthcoming aeronautical exposition to be staged by the Manufacturers' Aircraft Association in Madison Square Garden March 1-15 are rapidly assuming shape. At the present time fourteen manufacturers of complete airplanes and engines have been allotted space and thirty-three manufacturers of accessories of various kinds have signified their intention of exhibiting. These exhibits, of course, are in addition to those that will be made by the different army and navy departments. Following is the list of exhibitors to date:

Airplanes and Engines

Dayton Wright Airplane Co., Dayton.
Curtiss Aeroplane & Motor Corp., Buffalo.
L. W. F. Engineering Corp., College Point, L. I.
Wright Martin Aircraft Corp., New Brunswick.
Aeromarine Plane & Motor Co., New York.
Thomas Morse Aircraft Corp., Ithaca.
Burgess Company, Marblehead.
Gallaudet Aircraft Corp., East Greenwich, R. I.
B. F. Sturtevant Co., Jamaica Plain, Boston.
Packard Motor Car Co., Detroit.
Lawrence Aero Engine Corp.
Gio Ansaldo Co.
Cantilever Aero Co., New York.
L. Sperry Aircraft Co., New York.

Accessories

Empire Art Metal Co.; Arthur Johnson Mfg. Co.; Dodge Mfg. Co.; Valentine & Co.; Zenith Carbureter Co.; Wellington, Sears & Co.; John A. Roebling's Sons Co.; Eastman Kodak Co.; Motor Compressor Co.; Gold Light Mfg. Co.; Livingston Radiator Co.
American Balsa Co.; Jones Motrola Co.; Champion Ignition Co.; Dayton Eng. Lab. Co.; Ajax Auto & Sheet Metal Co.; Stone Propeller Co.; Splitdorf Electrical Co.; National Cash Register Co.; Jamestown Propeller Co.
American Propeller & Mfg. Co.; Hartzell Walnut Propeller Co.; Dayton Wire Wheel Co.; Lukenheimer Co.; General Ordnance Co.
Society of Automobile Engineers; Gardner-Moffat Co., Inc.; Torrington Co.; Goodyear Tire & Rubber Co.; Simms Magneto Co.; Triplex Safety Glass Corp.; Radium Dial Co.

More Men Hired Than Laid Off In Detroit

DETROIT, Feb. 6—The crisis in the labor situation in Detroit has passed. This week more men were hired than were laid off. Over 1000 men have been given employment, while those losing jobs numbered less than 800.

More men were made idle last week than during any other week in recent years. The American Car & Foundry Co. laid off 6000, Lincoln Motor Co. 500, while the Chalmers Motor Co. laid off its entire night shift due to completion of large Government contracts.

There are at present about 35,000 men idle in Detroit. The soldier situation seems to be taking care of itself. Eighty per cent of the men in uniform who registered with the U. S. Employment Office have been placed at work. A feature of the labor situation of late is a noticeable exodus of foreigners. In many local plants foreigners without full citizenship papers are being laid off and their jobs given to soldiers.

Contract Bill Before House

WASHINGTON, Feb. 11—The long pending bill for validation and settlement of informal war contracts aggregating $3,000,000,000, in which automotive manufacturers are interested to the extent of more than $300,000,000, was agreed upon to-day by the Conference Committee and was placed before the House for final action. The Senate passed the bill last week.

The agreement reached by the Senate and House conferees eliminates the section providing for an appeals commission, and also the McKellar amendment, which would have required War Department officials settling the contracts to make affidavits that they were not connected with any firm or had no personal interest in the contracts under settlement. Otherwise the bill is substantially the same as that passed by the Senate and published in AUTOMOTIVE INDUSTRIES last week.

Under the conference agreement, informal contracts, which include those not legally executed, are legalized so that they may be settled. Government officials will make the settlement and if dissatisfied, contractors may appeal to the Federal Court of Claims.

Herschell-Spillman Reorganized

NORTH TONAWANDA, N. Y., Feb. 12—The Herschell-Spillman Co. has been reincorporated under laws of Massachusetts with a capitalization of $1,750,000 and has taken over all the assets and property of the old company. Plans for extending the plant and increasing production are under consideration. B. W. Birdsall is president and general manager of the new company and associated with him are: Vice-president and chief engineer, E. O. Spillman; treasurer, Thomas C. Perkins; assistant treasurer and secretary, M. J. Tovell. The directors are T. J. Wilson, chairman; E. O. Spillman, Guy White, F. R. Switzer, Thomas C. Perkins and B. W. Birdsall.

Army Bill Abolishes M. T. C.

Pooling Inefficient and Standardization Lost Under New Bill—Operation and Maintenance Scattered

WASHINGTON, Feb. 12—The Army Appropriation Bill providing for 28,579 officers and 509,909 enlisted men, appropriating $1,117,289,488.56, orders the repeal of the Overman Act under which the Motor Transport Corps, Tank Corps and Aviation Corps were created for the emergency, and by its provisions abolishes the Motor Transport Corps and Tank Corps completely.

The aviation departments, both military and production, are recommended for continuation. The bill provides for the purchase, operation and maintenance of motor trucks and other motor vehicles by each individual army corps, such as the Engineers, Quartermaster, Ordnance and Signal Corps, and thereby reverts back to that condition which existed prior to the war, when the motor transport was not pooled and when each division purchased different types and sizes of vehicles, creating waste, confusion, extravagance and inefficiency, which finally resulted in the creation of a Motor Transport Corps for the purpose of pooling motor vehicles under one body.

Hearings of the House Military Affairs Committee which prompted this act have not been made public, and consequently causes are not available for publication at present.

It is thought in official circles here that either a vital omission was made accidentally on the part of the House Military Affairs Committee in thus scattering the purchase, operation and maintenance of motor vehicles throughout the army or that possibly some influence has brought

(*Continued on page* 395)

Naval Aviation Approved

WASHINGTON, Feb. 12—The House of Representatives yesterday passed the big Naval Appropriation Bill which includes appropriations for $25,000,000. This sum is for producing, constructing and operating and maintaining aircraft, aircraft stations, aircraft fields and experimental work. No more than $300,000 can be disbursed for drafting, inspection and messenger service for aircraft stations. No part of this appropriation can be expended for the maintenance of more than six heavier-than-air stations on the coasts of continental United States.

Automotive Industries

War Revenue Bill Passes

Measure Taxing Automotive Products Now Goes Before Congress for Approval

WASHINGTON, Feb. 7—The 1919 revenue bill, taxing passenger cars, motor trucks, tires, accessories, parts, truck express and taxicabs, among its numerous provisions, was agreed upon yesterday by the conferees and now comes before Congress for approval. It is anticipated that the bill will be passed promptly as it stands.

The provisions include a tax of 3 per cent on motor trucks, trailers and the equipment, including tires, tubes and other parts; 5 per cent on passenger cars and all other automobiles, including equipment, excepting on tractors, which are not taxed, and 5 per cent on tires, inner tubes, parts and accessories made for automobiles and sold to any person other than an automobile manufacturer. The floor tax on parts originally included is now eliminated. A tax of 1 cent for each 10 cents is assessed on tickets of admission and applies to automobile or parts shows held during the year.

Taxicabs, which includes all automobiles that carry passengers for hire, will pay a tax of $10 with a seating capacity of 7 or less and $20 for those machines with a capacity for more than 7 persons.

The tax of 3 per cent on motor truck haulage where it competes with rail or water transportation of freight remains in the bill, and in addition there is included a tax of 1 cent for each 20 cents paid for motor truck express where it competes with rail or water express, and 8 per cent of the transportation fee for carrying of passengers by motor truck, passenger car or motorcycle when it is in competition with rail or water carriers.

Following are excerpts from the bill, including those provisions most important to the automotive industries:

Sec. 800—That there shall be levied, assessed, collected and paid in lieu of the taxes imposed by section 700 of the Revenue Act of 1917:

(1) A tax of 1 cent for each 10 cents or fraction thereof of the amount paid for admission to any place on or after such date, including admission by season ticket or subscription, to be paid by the person paying for such admission.

Sec. 900. That there shall be levied, assessed, collected and paid upon the following articles sold or leased by the manufacturer, producer, or importer, a tax equivalent to the following percentage of the price paid for which so sold or leased:

(1) Automobile trucks and automobile wagons, including tires, inner tubes, parts and accessories therefor, sold on or in connection therewith or with the sale thereof, 3 per centum;

(2) Other automobiles and motorcycles, including tires, inner tubes, parts and accessories therefor, sold on or in connection therewith or with the sale thereof, except tractors, 5 per centum;

(3) Tires, inner tubes, parts or accessories for any article enumerated in sub-division (1) or (") sold to any person other than a manufacturer or producer of any of the articles enumerated in sub-division (I) or ("), 5 per centum.

Sec. 1000. That on and after July 1, 1918, in lieu of the tax imposed by the first subdivision of section 407 of the Revenue Act of 1916:

(II) Persons carrying on the business of operating or renting passenger automobiles for hire shall pay $10 for each such automobile having a seating capacity of more than 2 and not more than 7, and $20 for each such automobile having a seating capacity of more than 7.

Sec. 500—That from and after April 1, 1919, there shall be levied, assessed, collected and paid in lieu of the taxes imposed by section 500 of the Revenue Act of 1917:

(*Continued on page* 390)

Provisions in the Revenue Bill

Three per cent tax on motor trucks and trailers.
Five per cent tax on passenger cars.
Five per cent tax on tires, parts, accessories and inner tubes.
Ten per cent tax on shows.
Ten dollars annual tax on taxicabs seating 7 or less.
Twenty dollars annual tax on taxicabs carrying more than 7 persons.
Three per cent of transport cost for freight by truck in competition with rail or water.
Five per cent of transport cost for express by truck or passenger car in competition with rail or water.
Eight per cent of transport fee for carrying passengers by truck, passenger car or motorcycle in competition with rail or water.

Continue Rebating Duty on Tractors Valued Under $1,400

OTTAWA, Feb. 10—The Canadian Government has decided to renew the Order-in-Council passed on Feb. 7, last year, rebating the duty on tractors valued at $1,400 and under. These tractors, while practically coming in free, are not on the free list, the duty simply being remitted. The order will be renewed for an indefinite period.

Since duty on tractors of the value specified was removed, over 10,000 of that variety entered the Dominion, and the amount of duty rebated approximated over $2,000,000 for the fiscal year 1916-17. Only about 2000 of all kinds of tractors entered the Dominion previously.

Jobbers Not Guilty of Restraint

21 Members of Automotive Equipment Assn. Freed from Charges

NEW YORK, Feb. 11—The twenty-one members of the Automotive Equipment Association, formerly the National Association of Automobile Accessory Jobbers, and about half as many corporations, have been freed from all charges of monopoly and restraint of trade under the Sherman Law by the jury in the United States District Court for the Southern District of New York. Indications now are that the association will go forward into a successful future. Its growth and activity have been somewhat restricted during the year and a half that the trial has been pending.

The Sherman Law charge has caused the association to be a mysterious quantity in the trade since the finding of the indictment, Aug. 30, 1917. Prospective members have hesitated to join, not knowing what the status of the organization would be.

Judge Hand, in charging the jury, touched on most of the operative resolutions of the association, and stated that of themselves they were not restraint of trade, and that they meant little unless there were some ulterior intent proven.

The association successfully contended that it is not a price-fixing organization and has no monopolistic ambitions. Realizing, however, that some of its motives have been misconstrued, the organization now proposes to give a more definite understanding of its ideals with the object of continuing the trade betterment work it has been doing since its beginning.

The defense used only three witnesses, ex-Presidents Sidney F. Beech, T. M. Brooks and Charles E. Feath, each of whom explained the trade work the association has attempted to perform. Chief among the witnesses for the prosecution were syndicate catalog men, purchasing agencies and others who have had differences with the association's members.

Olds Building 100 Cars Daily

LANSING, Feb. 10—The Olds Motor Works is rapidly swinging into full production with 100 cars and 40 trucks daily. Passenger car production will be run up to 150 machines within 60 days and the daily truck output is being increased.

Rubber Imports 45% of Jan., 1918

Quantity Is Less Than for Same Month in Last Four Years

NEW YORK, Feb. 11—Importations of crude rubber into the United States during January, 1919, amounted to 7235 tons, as against 16,084 tons for January, 1918, and 11,292 tons for December last. This is also less than the imports for any one month during the past year except September and November, during which there were heavy restrictions on raw rubber importation. The present low import figure may be due to the fact that shipping space at the present time is limited for commercial products.

The following statistics for the month of January for four years have been compiled by the Rubber Association of America:

	1916 Tons	1917 Tons	1918 Tons	1919 Tons
January....	9,162	12,788	16,084	7,235

Labor Surplus Grows

WASHINGTON, Feb. 10—The surplus of labor in the United States is increasing rapidly, according to the U. S. Employment Service of the Department of Labor. Twenty-six states reported a surplus for the week ended Jan. 25, which is an increase of 19 states since Dec. 21.

More than 210,000 workers were unemployed according to reports received last week, while the current week shows a total of 265,000. The number of cities reporting surpluses has increased from 44 to 50 per cent. The number of cities reporting shortages decreased 1 per cent.

Cleveland, with 65,000 surplus, an increase of 10,000 for the week; Detroit, 33,000, as against 20,000 three weeks ago, and Buffalo, with 17,000 surplus, are the three cities reporting the largest surpluses. Akron reports 1500, Dayton 8000 and Toledo 9000 surplus. Reports of surplus workers are also received from California, New York, New England and through the Middle West. Slight shortages are reported from the South.

The total labor shortage of the 18 cities reporting shortages aggregates but 15,000.

The belt of unemployment, beginning in Illinois, extends east through Indiana, Ohio, along the lakes to Buffalo, up into and through Massachusetts; then south along the Atlantic seaboard to Florida and back toward Illinois through Tennessee and Virginia, skipping almost completely the State of Kentucky.

Two New Nash Models

KENOSHA, WIS., Feb. 10—The Nash Motors Co. has added two models to its line. These are a four-passenger model and a two-passenger roadster. It is expected that first deliveries will be made early in May. The four-passenger model has four doors and is built on a chassis with 121-in. wheelbase, the body having the popular beveled edge. Fenders and running gear are black with nickel plated trimmings. Stock equipment includes wire wheels equipped with cord tires.

War Revenue Bill Passes

(*Continued from page* 389)

(a) A tax equivalent to 3 per centum of the amount paid for the transportation on or after such date, by rail or water or by any form of mechanical motor power when in competition with carriers by rail or water, of property by freight transported from one point in the United States to another; and a like tax on the amount paid for such transportation which the United States or property transported from a point without the United States to a point within the United States;

(b) A tax of 1 cent for each 20 cents or fraction thereof of the amount paid to any person for the transportation on or after such date by rail or water or by any form of mechanical motor power when in competition with express by rail or water of any package, parcel or shipment by express, transported from one point in the United States to another; and a like tax on the amounts paid for such transportation within the United States of property transported from a point without the United States to a point within the United States;

(c) A tax equivalent to 8 per centum of the amount paid for the transportation on or after such date of persons by rail or water or by any form of mechanical motor power on a regular established line when in competition with carriers by rail or water from one point in the United States to another or to any point in Canada or Mexico where the ticket or order therefor is sold or issued in the United States, not including the amount paid for commutation or season tickets for trips less than 30 miles or for transportation the fare for which does not exceed 42 cents: provided that where such water transportation lines are in competition between American ports with foreign water transportation lines from adjacent foreign ports, the tax imposed under this subdivision of amounts paid for water transportation between American ports shall not exceed the amount of the transportation tax to which such foreign water transportation lines are subjected by their government corresponding to this tax.

Edmunds & Jones Corp. Has $737,319 Surplus

DETROIT, Feb. 11——For the year ending Dec. 31, the balance sheet of the Edmunds & Jones Corp. and its subsidiaries shows a surplus of $737,319, a decrease of $33,721 over 1917. Comparative figures for the two years follow:

Assets	1918	1917
Real estate, plants, machinery, etc., less reserves	$839,899	$833,083
Patents	1	1
Liberty bonds and other investments	92,619	21,200
Cash on hand and in banks	110,828	47,535
Accounts receivable	208,759	414,228
Inventories	677,834	852,814
Deferred charges	43,451	27,451
	$1,973,392	$2,196,312
Liabilities		
Accounts payable	$331,381	$421,699
Preferred stock	897,500	916,000
Reserve for income and war taxes	6,699	87,573
Uninvested balance of reserve for redemption of preferred stock	492	......
Surplus — Representing value of 40,000 shares common stock without par value, subject to payment of dividends on preferred stock	737,319	771,040
	$1,973,392	$2,196,312

The annual directors' meeting and the election of officers for the year will take place in about 10 days.

G.M.C. 1918 Surplus $29,940,780

$18,432,388 Increase Over 1917—The Net Profits Were $19,376,782

PONTIAC, Feb. 10—According to the balance sheet of the General Motors Corp. and subsidiary companies, including five months' operation of Chevrolet, for the 12 months ending Sept. 30, 1918, as compared with that for the 12 months ending Dec. 31, 1917, there is an increase of $18,432,388 in the company's surplus for 1918. The complete statement for the two years is as follows:

Assets	Sept. 30, 1918	Dec. 31, 1917
Real estate, plants, equipment, etc.	$76,144,354	$38,657,835
Good will	......	11,697,503
Patents, agreements, etc.	245,300	274,100
Investments in allied companies	9,158,730	2,030,273
Cash	23,335,327	18,865,645
Marketable securities	......	1,255,000
Liberty bonds	10,804,273	......
Notes and accounts receivable	23,483,734	13,595,538
Inventories	63,864,702	46,559,394
Deferred expenses	1,216,057	854,435
	$208,252,477	$133,789,724

Liabilities	Sept. 30, 1918	Dec. 31, 1917
Preferred stock	$19,684,300	$19,676,800
Common stock	105,996,400	76,873,300
Subsidiary companies' stock and surplus not owned by G. M. Corp.	1,732,339	1,399,583
Accounts and bills payable	13,252,659	10,665,718
Taxes, payroll, etc.	6,253,431	4,858,326
Preferred dividend payable	196,843	196,768
Reserve for depreciation, federal taxes, contingencies, etc.	31,195,725	8,610,936
Surplus	29,940,780	11,508,392
	$208,252,477	$133,789,724

Net profits, after expenses, taxes, depreciation, etc., were deducted, amounted to $35,718,459. After Federal taxes and other expenditures were made, the remaining net profit was $19,376,782. The amount held for outside shareholders was $332,756, the General Motors proportion being $19,044,026. Preferred dividends amounted to $885,769 and undivided profits to $18,158,257. The profit and loss surplus on Jan. 1, 1918, was $11,508,392, with the addition of $8,065,083 through the acquisition of Chevrolet assets on May 2, 1918. With the undivided profits of $18,158,257, the total was $37,731,732. Deducting the common dividend of $7,790,952, the profit and loss surplus amounted to $29,940,700.

New York Branch for Beckley-Ralston

CHICAGO, Feb. 11—The Beckley-Ralston Co. will shortly open a New York branch at 238-240 West Fifty-fourth Street. The branch is to be headed by James A. Abeles, who has resigned as vice-president and general manager of the Motor Car Equipment Co., New York, and disposed of his interests in that company to take up the new work.

Ford Must Distribute $19,000,000, But May Build Smelting Plant

Michigan Supreme Court Affirms Former Ruling for Distribution to Stockholders—Reverses Decision in Favor of Ford Expansion—Ford-Dodge Case Settles Three Important Points in Michigan Law

LANSING, Feb. 8—The Michigan Supreme Court Friday decided the famous legal action between John and Horace Dodge on one hand and Henry Ford and the Ford Motor Co. on the other. The decision is split, but Mr. Ford carries off the lion's share of the legal score, getting two points to the Dodges' one.

Special dividends, amounting to $19,000,000 were ordered paid to Ford stockholders by Judge Hosmer in the Wayne County Court, and this decree was affirmed. The higher court held that Mr. Ford was arbitrarily usurping the powers of the majority of stockholders, and was in substance making the rights and privileges of the other stockholders incidental to his altruistic plan to let the public have the benefit of company profits in a lower price for automobiles.

Decrees of the Wayne County Courts stopping expansion of the business of the Ford Motor Co. in its extensive smelting plant at River Rouge were overruled. In addition the court sustained the contention of Mr. Ford that the laws of Michigan, when they stop organization of a corporation for over $50,000,000, mean for organization purposes only.

Capital investments, such as the profits, borrowed money, are not controlled by the law limiting capitalization, according to the Supreme Court.

The Court assessed one-third of the cost of the case to Mr. Ford and two-thirds to Dodge Brothers.

The opinion was written by Justice Russell C. Ostrander. It consists of 20,000 words, and quotes at length from the briefs submitted by the attorneys on both sides, from the testimony, from newspaper interviews accredited to Mr. Ford and from letters which passed between the parties at litigation before the actual litigation began.

The case is of great importance to the State at large. It decides three important and perplexing points in Michigan law. These points were the backbone of the case. They are:

1—The rights of minority stockholders in a Michigan corporation.

2—The question whether an automobile company is going beyond the power granted it in the general manufacturing charter by the state, when it engages in the smelting of iron ore for automobile parts.

3—It interprets the meaning of "capital" in the Michigan law which puts a limit of $50,000,000 on a corporation's capitalization.

As to the first point, the court holds that the board of directors of a company must conduct the affairs of the company with the primary object to make money for the stockholders. When, however, the directors, dominated by the majority of the stockholders, apparently operate the corporation for purposes other than making money for the stockholders, they can be and ought to be stopped. They are entitled to retain a reasonable surplus, but when they try to take the profits belonging to the minority stockholders and put them to some other use, they are violating the rights of the minority and the courts can stop them.

Expansion of the business as proposed by Mr. Ford in his smelting plant, however, must not be considered as "some other use," for that expansion is held to be good business.

On the rights of Dodge brothers as stockholders, Justice Ostrander writes:

"It is the contention of the plaintiff (Dodge Brothers) that the apparent effect of the plan (the profit sharing plan with the public) is intended to be continued, and that it is deliberately proposed, not of record, and not by official corporate declaration, but nevertheless proposed, to continue the corporation henceforth as a semi-eleemosynary institution and not as a business institution. In support of this contention they point to the attitude and expressions of Henry Ford.

"Henry Ford is the dominant motor company. No plan of operation could be adopted unless he consented and no board of directors can be elected whom he does not favor. One of the directors of the company has no stock. One share was assigned to him to qualify him for the position, but it is not plain that he owns it.

"The records and especially the testimony of Mr. Ford convince that he has to some extent the attitude toward shareholders of one who has dispensed and distributed to them large gains and that they should be content to take what he chooses to give. His testimony creates the impression, also, that he thinks the Ford Motor Co. has made too much money, has had too large profits and that although large profits might still be earned, a sharing of them with the public, by reducing the price of the output of the company, ought to be undertaken.

"We have no doubt that certain sentimental, philanthropic and altruistic motives creditable to Mr. Ford had large influence in determining the policies to be pursued by the Ford Motor Co., the policy herein referred to.

"There should be no confusion (of which there is evidence) of the duties which Mr. Ford conceives that he and the stockholders owe to the general public and the duties which in law he and his co-directors owe to protesting minority stockholders.

"A business corporation is organized and carried on primarily for the profit of the stockholders. The powers of the directors are to be employed for that end. As we have pointed out, and the proposition does not require argument to sustain it, it is not within the lawful powers of a board of directors to shape and conduct the affairs of a corporation for the merely incidental benefit of shareholders and for the primary purpose of benefiting others, and no one will contend that if the avowed purpose of the defendant directors was to sacrifice the interest of the shareholders, it would not be the duty of the courts to interfere."

That section of the opinion which relates to the smelting works and in which Mr. Ford's plan for that are approved, does not lay down the flat law that an automobile manufacturing concern may go the limit from the transition of the varied raw material into the finished product, but it certainly leans that way. The court, however, notes that there must be special cases where such an argument could be stopped.

Claims Board Created to Settle War Contracts

WASHINGTON, Feb. 10—A War Department Claims Board has been created by the Secretary of War to supervise and co-ordinate the work of the various War Department agencies engaged in the settlement of claims resulting from the termination of contracts or other procurement obligations made necessary by the suspension of hostilities, and to authorize and approve such settlements. Through special representatives of the board, sitting with the various bureau boards of contract adjustment, the adjustments of the bureaus are subject to its scrutiny and approval. Adjustments involving matters of policy and of particular difficulty and importance are brought before the full board for decision.

The members of the War Department Claims Board are: President, Benedict Crowell, Assistant Secretary of War and Director of Munitions; G. H. Dorr, Assistant Director of Munitions; Brig.-Gen. George W. Burr, Assistant Director of Purchase, Storage and Traffic; Brig.-Gen. Herbert M. Lord, Director of Finance; Lieut.-Col. Herbert H. Lehman, Assistant to the Director of Purchase, Storage and Traffic.

Special members of the board are: W. H. Davis, for Ordnance Department contracts and obligations; Col. C. A. McKenny, for contracts and obligations of the Purchase and Storage Division; Major H. L. Goodhart, for contracts and obligations of the Chemical Warfare Service, Medical Corps and Signal Corps. Other special members may be appointed by the president of the board when necessary in connection with other procurement bureaus or agencies of the War Department.

Civilian Fliers Require Permits

WASHINGTON, Feb. 10—Civilians will not be permitted to make flights in the Army airplanes, despite the cessation of war activities, without authority from the Secretary of War, according to orders issued to-day by Major General William L. Kenly, Division of Military Aeronautics.

Hartford Automotive Parts Combines Two Companies

HARTFORD, Feb. 10—Negotiations have been consummated for the consolidation of the Hartford Auto Parts Co. and the Kinsler-Bennett Co., both manufacturers of universal joints and drives. The new company has been incorporated under the name of Hartford Automotive Parts Co., with a capital of $1,500,000. To provide additional manufacturing facilities it has purchased the plant formerly occupied by Billings & Spencer Co., and has taken possession. No change in management is contemplated other than a consolidation of the personnel of those identified with the former companies, and the association of Hollister, White & Co., bankers of Boston, who have a financial interest in the new company. James M. Carney, formerly of the Hartford Auto Parts Co., becomes chairman of the board of the new company, and the following are the officers: President, J. McA. Johnson; vice-president, F. R. Switzer; treasurer, H. A. Bigelow; assistant treasurer, T. C. Hudson. The directors include the above and H. A. Allen of the City Bank & Trust Co., and Shires Morris, president of Hart & Hegeman Co.

To Build a New Truck

NEWARK, OHIO., Feb. 11—The American Motor Truck Co., a new corporation, is making and will place a new truck on the market within sixty days. The new machine will be made in two sizes, a 1½-ton and a 2-ton machine. Later, a 3½- and a 5-ton truck will be produced, but not before the first of next year. The company will produce 300 trucks this year, the majority of which have already been sold. About a year ago this company purchased the assets of the Blair Motor Truck Co., but it will not make the truck manufactured by the Blair people in the past. Since incorporation, the American Motor Truck Co. has been running 20 hours daily on two-men tanks for the Government. This contract was recently cancelled and the company is now busy tearing out Government machinery and equipping the plant throughout for truck work. The officers of the new concern are: President, J. D. Potter; vice-president and production manager, E. B. Alspach; secretary and treasurer, H. S. McCoy; chief engineer, C. H. Doty, superintendent, H. E. Cavendish.

Henry Vice-President of Maxim Munitions

NEW YORK, Feb. 12—H. H. Henry has been made vice-president and general manager of the Maxim Munitions Corp., 120 Broadway. He was formerly president of the Dart Motor Truck Co., Waterloo, and came East only a few days ago to direct the work of merchandising Maxim tractors along the Atlantic seaboard and abroad.

Trippensee Buys Wolverine Plant

DETROIT, Feb. 11—The Trippensee Mfg. Co., makers of automobile bodies, has bought the plant of the Wolverine Mfg. Co. The property covers 6½ acres with 250,000 ft. floor space with two railroad sidings. The company has already taken possession and it is understood they will commence production at once on closed body work, providing employment for 1600 men.

Harroun Plans for 1919

DETROIT, Feb. 10—The Harroun Motors Corp. is back to 100 per cent peace time production and plans during February to turn out 200 cars, then 500 and gradually increase the number during the spring and summer until the maximum output is reached. The plant is able to make 250 engines and assemble an equal number of cars per day, double shift. The Harroun plant finished its manufacture of shells for the Government on Jan. 31.

Harroun activity for the Government in November showed that 90 per cent of the plant was devoted to shells, 5 per cent to class B truck engines and 3 per cent to Fordson tractors. The whole plant was working on 10,000 tractor shoes, the creeping caterpillar type of walking shoe used as a tread on the wheels of the Government 6-ton tractors. Production of these tractor shoes was about 700 a day. Of the contract for 10,000 cylinder water heads for Fordson tractors, 5000 were turned out on an average of over 100 per day. Notwithstanding Government work, the Harroun plant was able to make 2400 cars from parts on hand.

This concern desires to manufacture its car complete in its own plant as far as possible, and is seeking a body plant, a transmission plant, a universal joint plant and an axle plant, which, when combined with the present plant, will include all the major units necessary for the manufacture of Harroun cars.

Reliance Reorganizes Directorate and Personnel

APPLETON, Feb. 10—The Reliance Motor Truck Co. has reorganized its directorate and official personnel. John M. Balliet, Appleton, has been elected president and general manager, succeeding Ira L. Miller, Racine, who has retired. M. Weyenberg succeeds Mr. Balliet as vice-president. T. F. Purtell, secretary, also has resigned and is succeeded by A. G. Brusewitz, who has been county highway commissioner at Appleton. August Brandt is an additional director. Its new $75,000 plant has been placed in full operation and is manufacturing trucks as well as the former Piggins internal spur-gear drive rear axle for trucks.

Truck and Tractor Engine Governors

(*Continued from page* 375)

equalize this pressure. This offset is governed by the size, angle and gas velocity, but is generally about 1/32 in.

Fig. 7 shows a particular type of disk brought out by one of the large engine manufacturers and serves the same object as offsetting the butterfly stem. The angle on the right is 17 deg. and the left is 25 deg.

There are other types, such as piston valves, gate valves, plates, grids, etc. The piston valve may be balanced but the other types impose more or less extra load on the governor, due to the force of incoming gases. The butterfly valve seems to have the call, as it is serviceable, easily manufactured and installed.

We have now considered some of the elements of a governor. Fig. 8 shows one of the most recent tractor governor designs. This is a very compact, efficient governor, equipped with a simple speed changing device and a spindle spring instead of the double springs frequently used. The governor works through a circular rack and pinion instead of the typical sliding collar.

Fig. 9 shows a complete governor and governor valve installation, as used by one of the largest tractor manufacturers. The weight yoke is bolted directly to the camshaft and the weights operate the spindle *O*, which actuates the governor arm *E*. The casing *F* is bolted to the motor housing and all parts are lubricated from the crankcase. The speed changing device is shown at *J*. The manual control is shown at *W* and is spring mounted.

Commerce Back in Commercial Work

DETROIT, MICH., Feb. 11—The Commerce Truck Co. is winding up its war contract work and is now running approximately 50 per cent on commercial production. Uncompleted Government contracts call for 300 war trucks, but these will be completed within 30 days. This company is now running 15 commercial trucks daily.

Roamer to Make 2000 in 1919

KALAMAZOO, Feb. 11—The Barley Motor Car Co. has been running normal capacity for thirty days, and expects to increase its production 200 per cent within the next months. Four machines are turned out daily. The 1919 production schedule calls for 2000 machines.

Seymour Buys Eisemann

BROOKLYN, N. Y., Feb. 12—The Eisemann Magneto Co. has been sold by the Alien Property Custodian to the Seymour Mfg. Co., Seymour, Conn. This company has been a factor in the brass casting field. It acquires 1500 of the 2000 shares in the Eisemann company, the remaining 500 being retained by R. Kny, president of the Eisemann company. Though nothing definite has been made public regarding the plans of the Seymour company, it is understood that the Eisemann business will be continued.

Airplane Show for Chicago

CHICAGO, Feb. 11—Chicago will hold its first airplane show at the Coliseum, March 29 to April 5. Louis Disbrow is the promoter. He and George W. Browne, Wisconsin distributer for Willys-Overland and distributer in Wisconsin and Illinois for Curtiss, have formed the International Airplane Exposition Co., and may put on similar shows elsewhere. Four Curtiss planes are promised for exhibition. Bart J. Ruddle of Milwaukee, will manage the show.

Mile Record for De Palma

NEW YORK, Feb. 12—Ralph De Palma is reported to have set up a new record for a straight-away mile on Daytona Beach, covering the distance in 24.02 seconds, which is at the rate of 148.875 m.p.h. The kilometer is reported to have been covered in 15.86 seconds. The Contest Board of the American Automobile Association officially observed the trails, but has not yet received confirmation of the time.

Moon Motor Car President Dies

ST. LOUIS, Feb. 12—Joseph W. Moon, president of the Moon Motor Car Co., died last night after a year's illness from hardening of the arteries. He was born in Brown County, Ohio, 66 years ago. In 1882, he came to St. Louis, and, with his brother, J. C. Moon, organized Moon Bros. Carriage Co. Ten years later he formed the Joseph C. Moon Buggy Co., of which he was head. At the time of his death he was also vice-president of the Scheler Implement Co.

197 Exhibitors for Kansas City

Sixty-six Tractors, 131 Accessories Take Space for National Tractor Show

KANSAS CITY, Feb. 10—Arrangements for the National Tractor Show to be held here during the week of Feb. 24 to March 1 are rapidly taking shape, and it is expected that the exhibition will draw a record attendance.

At this time 66 manufacturers of tractors and 131 manufacturers of accessories of various kinds have signed up for space. The following is a partial list of tractor and accessory exhibitors:

83 French Makers at Lyons Fair

Every Important Maker on List—Little American Representation

PARIS, Jan. 20—Automobile and accessory manufacturers to exhibit at the Lyons samples fair during the first fortnight of March will number eighty-three, according to the final list just published. All these firms will be in one building. The Lyons fair will thus constitute the first automobile show in France since the war.

The list comprises practically every automobile manufacturer of importance in France, including a certain number of newcomers who, before the war, were only indirectly connected with the automobile industry.

There is very little American representation. Goodrich and the United States Rubber Co. will be at the show, and the French agent of the Overland has secured space. Ford does not appear on the official list, but it is believed that its French representative has also reserved space.

It is expected that a number of new cars will be presented at the Lyons fair. The time for preparation is short, but motor men are all working hard to send new types to this exhibition. Where the actual cars cannot be shown, representatives will be on hand to supply information and issue particulars. The fair is open to all but enemy nations.

U. S. Provided 80 Per Cent of Allied Petroleum Requirements

WASHINGTON, Feb. 8—"If you don't keep up your petroleum system we shall lose the war." This cablegram from Marshal Foch, and a later one reading "Highest command informs that position has become so serious that change in military operations will have to be contemplated unless increased deliveries of gasoline at front are made possible," were given out to-day by the United States Fuel Administration as the real causes for the gasoline-less Sundays of the fall of 1918. The gasoline shortage in France, it is said, was so serious that complete alterations of the campaign would have been necessary had it not been for the timely shipments by the United States, which provided 80 per cent of the Allied requirements of petroleum products during the war.

N. A. D. A. New St. Louis Address

ST. LOUIS, Feb. 10—The address of the National Automobile Dealers' Association is now 5124 Locust Street. Business Manager Harry G. Moock moved to his new location Friday.

$2,000,000 Asked for Air Mail Service by Assistant Postmaster General

30 Successful Air Mail Routes in Italy, France, Great Britain, Greece, Denmark, Germany, Spain and Austria—Suggests Boston-Atlanta, New York-San Francisco, Key West-Havana Lines

WASHINGTON, Feb. 10—A request for $2,000,000 for the development and extension of air mail routes in the United States was made by Otto Praeger, Second Assistant Postmaster General, in a letter to Congress. The letter, written as an argument in favor of the $850,500 appropriation for air mail contained in the post office bill now before the Senate, stated that 30 airplane mail routes have already been established and successfully operated in Italy, France, Great Britain, Greece, Denmark, Austria, Norway, Spain and Germany, and that many more are contemplated in those countries.

The first route established in the United States between Washington and New York, states the letter, cost $75,165 to operate in the past year as against a revenue of $60,653. The cost as estimated includes a bookkeeping charge of 6 per cent interest on the investment and 33 1/3 per cent depreciation. It was considered an excellent showing in view of the fact that it was the first experiment, and that the route was short and not between two points of high industrial contact. The route was established, says the letter, "not as a typical commercial line, but to solve the problems that had to be met on a daily dependable schedule."

An appropriation of $2,000,000, it was stated, would allow for the establishment of routes between Boston and Atlanta, New York and San Francisco, Key West and Havana, and other points between these cities by means of feeder lines. The War Department planes, and especially those of the De Haviland type, says the post office, are unsuited for mail work. New planes are needed. This accounts for the large sum asked.

Following is the complete statement:

Memorandum on Aerial Mail Service

January 30, 1919.

The Aerial Mail Service was inaugurated May 15, 1918, and during the first six months of its existence its operations covered 68,892 miles, at a cost of $75,165.94, including 6 per cent on investment and 33⅓ per cent for depreciation. In that period it carried between Washington and New York 7452½ pounds of aeroplane mail. The revenue derived was $60,653.28. The net deficit, not taking into account the 6 per cent interest on investment, was $8,969.08. In addition to the aeroplane mail carried there was dispatched between Washington, Philadelphia, and New York in the six months' period a total of 31,926½ pounds of first-class mail, aggregating 3,667,040 letters. This mail was advanced in dispatch from 6 to 16 hours, which many times made up for the small deficit in operation of this service. This ordinary mail was letter mail from distant States, which was carried in addition to the aeroplane mail. Thus the ordinary mail put on the planes at Washington was usually mail from the South Atlantic Coast States and the Gulf States, distributed to carriers by the Railway Mail Service before reaching Washington, and by reason of aeroplane dispatch was delivered in New York on the same afternoon instead of the following morning.

The Washington-New York route was established not as a typical commercial line, but to solve the problems that had to be met to establish a daily dependable schedule. The flying record made on the New York-Washington line has never been equaled in the history of aviation, and its operation by civilian fliers of the Post Office Department has far exceeded its operation while under military control, the civilian fliers having a record of but 7 forced landings in 100 consecutive flights and only 2 failures in that time on account of fog or storm conditions. The mail has been carried in blinding rain and hail, on fog-bound days with visibility of not over half a mile, and in the face of gales. Only two winter gales were strong enough to prevent the aeroplanes from completing their journey. On Thursday, January 23, the mail was brought south as far as Silverside, Del., in the face of a 65-mile gale at an altitude of a few thousand feet.

The fastest time of flight carrying the mail from College Park to Belmont Park, N. Y., a distance of 218 miles, was 1 hour and 30 minutes, and the slowest time for a continuous flight was 4 hours and 56 minutes. The average time is 2 hours and 40 minutes. The common experience of the users of aeroplane mail is that a letter posted in the down-town stations in Washington as late at 10.50 a. m., and leaving the aviation field at 11.30 a. m., is usually delivered between 4 and 4.30 in the afternoon, which is ample time before close of business.

Extension of Service

The greater the distance between the points on an aerial mail route the greater is the service rendered to commerce and the greater is the patronage of the line. A mail service leaving New York at 6 in the morning and arriving in Chicago before 3 o'clock in the afternoon, in time to connect with carrier deliveries, will advance the mail between the two cities by 16 hours over any train dispatch that can be made after the departure of the Twentieth Century Limited from New York at 2.45 p. m. The department desires to establish this line immediately and extend it west to the foot of the Rockies during the coming fiscal year, with the view of reaching the seaports of Seattle and San Francisco, if Congress authorizes the appropriation necessary. The air mail time between New York and San Francisco will be less than 40 hours. It is desired that this transcontinental trunk line shall be tapped by lines from Minneapolis, St. Paul, St. Louis, Kansas City and other points, and ultimately by a line from Boston, via Albany, Buffalo and Detroit, to Chicago.

A north and south trunk line from Boston to Atlanta should likewise be established, with an ultimate extension from Boston to Montreal, Canada, and from Atlanta, via Key West, to Habana. Based on the accurate cost accounting kept in the operation of the Washington-New York air mail line, the cost of an east and west trunk line from New York as far west as Omaha and a north and south trunk line from Boston to Atlanta has been carefully estimated at $1,600,000. To this should be added $400,000 for several essential feeders that would connect up Detroit, Minneapolis and St. Paul, St. Louis, Kansas City and other points, and would admit of an extension as far west as Salt Lake City, this extension, however, dependent upon the extent to which the Government equipment can be transformed into strong and safe mail-carrying machines.

For this reason it would be very desirable to obtain an appropriation of $2,000,000 for the ensuing fiscal year.

Equipment

The Post Office Department has made a sincere effort to comply with the general and natural sentiment that the war planes left over at the conclusion of hostilities should be utilized in carrying the mails. The attempt at once developed that the DH-4's, of which more than 1000 are said to be available, are too lightly built for commercial work. They were produced in immense haste for light war purposes, to rise from a prepared field, drop a certain number of bombs, fire machine-gun ammunition, and return to a prepared aerodrome empty. When required to make forced landings because of engine trouble they crumple up in a majority of cases, frequently crippling or killing the pilot. The single casualty and the single case of serious physical injury sustained in the operation of the aerial mail service in this country, covering 93,463 miles of operation, were sustained in the persistent and conscientious effort made by the Post Office Department to utilize the DH-4 for cross-country commercial work. Single-motor planes must be expected to occasionally develop engine trouble, which necessitates a forced landing for readjustments. These forced landings must be frequently made over fields that are soft from rain or with holes, gulleys, or small obstructions that will turn a plane upon its back while coming to a stop on the ground. Whenever this occurs to a strong commercial machine, such as is used on the New York-Washington run, the damage is usually slight and the delay not serious.

However, when a DH turns turtle in such landings, it generally sustains more serious injury. In a majority of the cases it fairly crumples up, resulting in bad spills or injury for the pilots. This is the result of the light construction of the planes, which makes them unavailable except possibly for the special war purposes for which they were designed.

There are also in this country, which might be available for mail service, a number of twin-motor Handley-Pages. These planes are of a slow type, with an average speed loaded of from 70 to 90 miles, according to the characteristics of the individual plane. It requires the two engines to keep it in the air with a load, the result being that with one engine getting out of order the twin-motored Handley-Page of the type that was built in this country will come to the ground, although the other engine is intact and operating under full power.

Just as the war was coming to a close certain American manufacturers created twin-motor planes which surpassed anything in that line on the battle front. These planes have sufficient speed to make better than fast railroad time against the severest wind-storms; also they can continue on their course in the air with a load against head winds with one engine operating. They can be built strong enough for commercial purposes and will prove satisfactory mail machines.

In the expenditure of any appropriation made by Congress it would be the policy of the Post Office Department first to use such of the De Haviland machines as can be rebuilt and strengthened with reasonable cost. A rebuilt plane of this character has been completed and is undergoing tests to ascertain whether it will be a dependable and safe machine. The services of some of the best aeronautical engineers of the country generously have been placed at the command of the Post Office Department to assist in solving the problem of making the surplus war planes suitable for commercial cross-country work. Should all these efforts fail to develop out of the war material a practical mail-carrying machine, it would be the purpose of the Post Office Department to call upon manufacturers for designs and bids for a commercial twin-motor machine of reasonable cost for carrying the mails. It is believed that with readjusted conditions in the aircraft industry with the cessation of war orders it will be possible to obtain such machines for considerably less than $20,000 by utilizing surplus parts and engines which the War Department has put at the disposal of the Post Office Department.

Army Co-operation

It has always been the policy of the Post Office Department to seek the fullest co-operation with the Army and Navy Departments in their training programs, so that the military personnel and equipment used in military training might incidentally render a civic function in carrying the mails. The Post Office Department has offered to take details of Army fliers and Army mechanics and to utilize war equipment in carrying the mails to such an extent as the military authorities may deem the practice gained by its personnel in the mail service of training value. In this co-operation the Post Office Department has pointed out that the maintenance of mail schedules must be the prime consideration, and that this can be obtained only through placing the men detailed to the Post Office Department under the direction and control of the Postmaster General during the period of such detail. The service can be operated from the standpoint of maintaining mail schedules more efficiently by the Post Office Department. Likewise

the service can be operated at a much less cost to the Government by the Post Office Department than it can be operated by a military branch, notwithstanding the higher wages paid to civilian aviators and mechanics, for the reason that it is the policy in the military branches to be more lavish with men and materials than obtains in civilian operations.

The extent of the expansion of the aerial mail program in this country will naturally depend upon the amount of co-operation that the military authorities may finally determine would be of value in their air training program. This factor, however, is a matter of uncertainty, and it is therefore desirable that Congress should make an appropriation of at least $2,000,000 that a substantial aerial mail service may be inaugurated, independent of the final determination of the military authorities as to the value and the extent of utilizing the aerial mail service as an adjunct to their training program. If this is not done it is probable that this country at the end of a year will find itself as far behind in the commercial development of aviation as it found itself in military aviation upon entry into the recent war.

OTTO PRAEGER,
Second Assistant Postmaster General.

Italy's Truck Exports Decline in 1918

NEW YORK, Feb. 10—Italian motor vehicle exports showed a falling off for the first six months of 1918, compared with the corresponding period of the two preceding years. From Jan. 1 to June 30, 1918, there were exported a total of 2356 trucks and touring cars, having a total value of approximately $7,000,000, compared with a total of 4148 vehicles in 1917 and 2731 in 1916. The number of touring cars exported during the first six months of 1918 was 728, this constituting a record, for the figures of the two preceding years were 244 and 569 respectively. The decrease was on the trucks, which dropped from the high figure of 3904 for the first half of 1917 to 1628 for the first half of the past year.

Italian imports of motor vehicles were very low during the first half of 1918, the value being about $75,000 for 92 touring cars and one truck. For the corresponding period of 1916 the figures were 178 trucks and nine touring cars. The following are the detailed returns, as issued by the Ministry of Finance:

AUTOMOBILE EXPORTS FROM ITALY

Six months ending June 30, 1918

	Trucks		Cars		Total	
Yr.	No.	Value	No.	Value	No.	Value
1916	2162	$4,791,056	569	$977,720	2731	$5,768,776
1917	3904	9,937,462	244	623,946	4148	10,561,408
1918	1628	3,898,080	728	1,836,160	2356	5,734,240

AUTOMOBILE IMPORTS INTO ITALY

Six months ending June 30, 1918

	Trucks		Cars		Total	
Yr.	No.	Value	No.	Value	No.	Value
1916	9	$14,840	178	$289,828	187	$304,668
1917	10	5,600	59	85,920	69	91,520
1918	1	4,000	92	56,112	93	60,112

Hawthorne, Hamilton & DeLoss Merged

BRIDGEPORT, Feb. 7—The Hawthorne Mfg. Co. and the Hamilton & DeLoss Co. have been consolidated under the style Hawthorne Mfg. Co. The Hawthorne company was a maker of spot lamps and other automobile lights, and the Hamilton company's business was sheet metal products.

"Working Condition Service" Created

To Look After Health and Safety and Promulgate Labor Standards

WASHINGTON, Feb. 8—The Department of Labor has created a Working Conditions Service to investigate working conditions, determine standards and adopt regulations for the maintenance of such standards. The service will co-operate with State authorities. In order to properly function the service has been divided into three groups—health, safety and relations between the groups necessary to production. These will be known as the:

Division of Industrial Hygiene and Medicine.
Division of Labor Administration.
Division of Safety Engineering.

The Division of Industrial Hygiene and Medicine program proposes:

To make studies of working conditions in their relation to health to determine hazardous processes and methods;

To formulate sanitary codes and regulations to meet health hazards in the various industries;

To formulate standards of medical practice in industries, to co-operate in the betterment of medical service in industries and industrial centers;

To determine standards of physiological requirements of various occupations;

To determine methods for proper placement of workers;

To secure statistical data of industrial morbidity;

To promote facilities for the education and training of physicians and sanitarians for industries;

To assist industries in obtaining physicians and other technicians for industrial service;

To disseminate information concerning measures necessary to safeguard workers against industrial health hazards, and to secure co-operation of all elements, governmental and private, in furtherance of the industrial health program.

The Division of Labor Administration includes in its program:

Studies of employment systems and labor management policies, such as methods of hiring, selecting, inducting, and assigning employees to their duties, in order to determine causes of labor turnover and to avoid unnecessary rotation of labor.

Assisting industrial managers in studying their individual employment problems and advising them as to the best methods of hiring and selecting employees, reducing absenteeism and irregular employment, handling grievances, eliminating friction, and stimulating morale among the employees.

Establishing a national information center on employment and labor administration policies for the use of industrial managers, educational institutions and others, and distributing information.

Formulating standard policies of labor administration, and with the aid of a committee representing all interests affected, promulgating these standard policies to the country and urging their adoption by the industrial managers.

Acting as counselor or consultant on employment methods and policies, and assisting industries to put into operation the standard practices that are recommended.

Promoting facilities for training of labor administrators and assisting industries in obtaining such trained men for their plants.

The Division of Safety Engineering will include:

A study of the hazards of different industries and the determination of safety standards and codes to overcome such;

The encouragement of experiments on safety appliances and practices and the exchange of ideas concerning the same among industries specially interested;

In establishments where exceptional hazards are an integral part of industry, such as mines and explosive plants, the encouragement of co-ordinated plans by safety and medical supervisors to care for the victims in emergencies.

The standardization of record cards, survey forms, filing systems, charts and analytical procedure and presentation to enable safety engineers to have uniform systems for the collection and interpretation of data on plant hazards and injuries; the systematic elimination of the more serious hazards; the protection afforded the workers and like facts which justify the retention of safety work in plant management.

Army Bill Abolishes M. T. C.

(*Continued from page* 388)

about this arrangement, probably by suggestion to the committee.

It is known that none of the army officers connected with the Motor Transport Corps testified with regard to the functions or importance of that corps to the committee. Amazement at the provisions of the bill is displayed, and particularly so because of the proof that motor transport must be pooled in this country from the experiences of France and Great Britain. The bill as it now stands, allowing each corps to operate and maintain its own trucks and other vehicles means a complete cessation of the standardization plan and a renewal of the original system whereby hundreds of types of trucks were operated and necessitated the maintenance of great stores of parts for maintenance and repair.

One of the first lessons that came out of the war was that idle trucks were a frequent result of the operation of trucks under different corps. There was no correlation of work. One corps cannot use the trucks of another corps.

An effort will be made, it is understood here, to present this matter properly before Congress and urge an amendment which will make an appropriation for the Motor Transport Corps and take the purchase, operation and maintenance of trucks from the other divisions, or pooling under the motor division. That either this step or the pooling of all the motor vehicles under the Quartermaster Department in one division is vitally important to the army, is the statement made by many army officers.

The army bill provides $4,000,000 for the Signal Corps, $10,000,000 for military air service, $449,000,000 for the Quartermaster Department and $3,000,000 for the Ordnance Department, and specifically states that these funds, in addition to the purchase of other supplies for each of these departments, are also for the "purchase, hire, operation, maintenance and repair of motor propelleld vehicles" by each of these respecttive departments.

Five hundred thousand dollars is also provided for the Ordnance Department for the purchase, manufacture and maintenance of armored motor cars. The sums appropriated are to remain available until December 31, 1920.

The legislative section of the bill provides for the repeal of the Overman act, an "act to authorize the President to co-ordinate and consolidate executive bureaus, agencies and offices in the interest of economy and more efficient concentration of the Government."

It authorizes the President to continue any such corps as he shall deem necessary, but since motor-vehicle appropriations have been made directly to each specific army corps, completely ignoring the Motor Transport Corps, that division could be continued only as a body without functions.

Furthermore, the statutes specifically state that the head of one department cannot disburse funds which have been appropriated in the name of another department, and even though the President might see fit to continue the Motor Transport Corps as such, it would be left without functions or funds, under the present provisions of the army bill.

One amendment which has been suggested and may be proposed for the army bill provides that all motor cars, trucks, trailers, motorcycles, and bicycles shall be under the Motor Transport Corps as regards engineering, purchase, operation and maintenance except armored cars and tractors and tanks, which will remain under the Ordnance Department.

It also specifies that all appropriations for motor cars, trucks, trailers, motorcycles and bicycles should be placed at the disposal of one department, and further that the special bodies required by each army division such as the ambulance for the Medical Corps, and pigeon carriers for the Signal Corps are to be designed by the respective departments to fit the standard chassis as specified by the Motor Transport Corps.

American vs. German Exports

U. S. A. the Leader in Each of the Five Years Preceding the World War

	1909	1910	1911	1912	1913
Value of Germany's total exports of passenger cars	$4,066,000	$6,931,000	$10,099,000	$15,483,000	$16,897,000
Value of U. S. A.'s total exports of passenger cars	5,387,021	9,548,700	12,965,049	21,550,189	24,275,793
Value of German passenger cars exported to U. S. A.	193,580	368,219	297,153	259,313	261,168
Value of U. S. A. passenger cars exported to Germany	136,966	265,218	209,663	226,227	764,389

NEW YORK, Feb. 7—German commercial efficiency has been lauded to such an extent in the past that it may be a surprise to many to learn that during the five years preceding the war the United States not only exported cars to a greater value in each individual year, but sold to Germany passenger cars of a total value of $1,602,463 as against Germany's sales to the United States of cars valued at a total of $1,379,433 during the five years. A table giving Germany's and the U. S. A.'s passenger car exports by principal countries is published herewith.

A study of this table reveals the fact that certain countries, notably Russia, have been large importers of German cars. The geographical location of these countries is probably one reason for supporting the German industry, but another is that Germany has in the past given careful study to the requirements of each individual foreign customer and has not only furnished products which measure up to the local (and often arbitrary) standards, but has given the long credits customary. We, on the other hand, have furnished standard cars and, in the great majority of cases, have insisted that payment for them be made in accordance with the practice current in this country.

In 1913 Germany's total passenger car exports were valued at $16,897,000, as against the U. S. total of $24,275,793. Since 1913-14 Germany's export trade may be indicated by a zero sign, whereas in 1917 our exports of passenger cars alone were valued at $48,612,632, a high-water mark more than double our figure for 1913. In 1918 our car export figures receded a little, but were well maintained in view of the shortage of ocean transport, a gasoline famine which was practically world-wide and an almost universal lack of tires owing to restrictions affecting the supply of crude rubber.

Germany has ceased to be a competitor for the world's automotive markets for the time being, but England, France and Italy are making strong bids for trade with post-war models and prices which will be lower in all probability.

Value of Passenger Cars Exported by Germany and the U. S. A. for Five Years Before the War

Exported to	By	1909	1910	1911	1912	1913
Argentina	Germany	$76,000	$247,000	$589,000	$1,480,000	$1,228,000

German Truck Train Organization

Run on Fuel Substitutes and Steel Rims—Gasoline Reserved for Air Force

By W. F. Bradley

PARIS, Jan. 20—Two types of automobile truck trains exist in the German army. These are known as Army columns and Division columns. An Army column, or truck train, consists of 18 trucks of 4 ton capacity, one of which is a traveling workshop. The effective tonnage is thus about 60. Attached to this train are two passenger cars, one or two motorcycles and a trailer kitchen. This organization is practically the same as that adopted by the French. The staff of an army truck train comprises a captain and a lieutenant, one sergeant-major, four or five non-commissioned officers and 51 men.

The Divisional truck trains comprise ten trucks of 4 ton capacity, one of which is a workshop, and this train has a practical tonnage capacity of 30 tons. There is also one passenger car, one motorcycle and one kitchen trailer. The staff of such a truck train consists of an officer, a sergeant-major, four to five non-commissioned officers and 30 men. The Divisional truck trains are made use of for all kinds of transportation required by the division.

Early in the war the German army made use of some special types of meat-carrying trucks. These, however, were abandoned later, and two or three ordinary trucks from the train were given this work.

The Army columns or trains were designed to supplement the Divisional trains, and were employed especially for carrying munitions from the rear to the dumps or batteries. Repairs were handled in the German army by repairshops, usually one for each army.

The real rubber shortage in the German army made itself felt in 1916. Up to this time all cars and trucks had been run on rubber tires. Suddenly rubber disappeared from the trucks and steel rims or wood blocks, sometimes surrounded by a steel rim, were made use of everywhere. At the same time every automobile unit was give only one truck equipped with rubber tires. This vehicle was used for carrying delicate objects and also as a break-down truck.

With either wood or steel tires it was impossible to obtain sufficient adherence to tow other vehicles. Pneumatic tires were only used on light cars and ambulances operating in the advance zone. All vehicles on the lines of communication or in the zone of the rear were equipped with various types of steel tires. Many of these had coil springs interposed between the outer rim and the wheel.

It is interesting to note that the German army employed "Continental" and "Oberspree" tires almost exclusively. A

certain number of Michelin tires were in use until 1917. It is not known whether these were requisitioned in the invaded districts of France or whether they were made in moulds stolen in France. In any case, the fact that these tires were available until 1917 indicates that rigid economy was effected in their use.

For a long time before the end of the war the automobile service of the German army was altogether deprived of gasoline, this fuel being reserved for the air service. During practically the whole of the war trucks and passenger cars were run on benzol or on a mixture of benzol and alcohol. During one particular period, in 1916, the fuel employed consisted of 40 per cent benzol and 60 per cent alcohol. As neither engines nor carbureters had been built for this fuel results were very unsatisfactory, and it was not long before the percentage of alcohol was reduced.

It is stated that the German army was never totally out of fuel, but at all times the service was restricted because of shortage. As in the case of the French army since 1917, all German automobile units had a ration supply of fuel. When this supply was exhausted the cars remained in the garage, in some cases for two or three months.

Foreign Trade Opportunities

WASHINGTON, Feb. 8—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has inquiries for the agencies of automobiles and tractors. Full information regarding each of the following can be secured by addressing the Bureau of Foreign and Domestic Commerce and referring to the foreign trade opportunity number.

A man in Norway desires to purchase an agency for the sale of automobiles and accessories. Foreign Trade Opportunity No. 28120.

An agency is desired by a man in France for passenger cars. Correspondence should be in French. No. 28121.

An agency for passenger cars, oils and greases is desired by a man in France. Correspondence should be in French. No. 28125.

Requests for an agency for passenger cars, bicycles and tool supplies has been received from a man in France. Correspondence may be in English. No. 28127.

A company in Sweden desires an automobile supplies and accessories agency. Correspondence may be in English. No. 28130.

A firm in Spain desires to secure the sole agency and to act as purchaser of farm tractors for the Balearic Islands. Quotation should be made f.o.b. New York, cash against documents. Correspondence may be in English. No. 28126.

A business man in Spain desires an agency for automobiles, tractors, petroleum and gasoline. Correspondence should be in Spanish. References have been filed. No. 28134.

A business man in France desires an agency for automobiles and tractors. Correspondence in English. No. 28155.

A business man in France desires an agency for passenger cars, tractors, trucks, petroleum, gasoline and heavy oils for Morocco. Correspondence should be in English. References have been filed. No. 28141.

A man in Algeria desires an agency for motor cars. References have been filed. Payment against documents or confirmed credit. No. 28150.

A business man in France desires an agency for passenger cars and tractors. Correspondence in English. No references have been filed. No. 28155.

A commercial agent in France desires a farm tractor agency. Correspondence in French. No. 28137.

An agency is desired in France for farm tractors. Terms, cash on delivery to France. Correspondence in French or Spanish. No. 28143.

Australia Expects Big Developments in Automotive Business

Activities Have Been Curtailed by After-War Conditions and Heavy Taxation, but Revival Is Imminent—Expected Reaction in Favor of European Cars—No Shortage of American Products

SYDNEY, N. S. W., Jan. 3—There are several circumstances which in combination have had the effect of slowing down the automotive business in Australian cities for some time past. In the first place, the country has been suffering from a severe drought which has practically ruined the wheat crop. Fires have caused a lot of damage to farms and cattle in Northern Queensland, and the general effect has been detrimental to the sale of automotive products.

A second reason for business slackness lies in the fact that last season's wheat has not yet been shipped, and the farms do not expect to get a remunerative price for it. The Government has paid about 84 cents a bushel for it so far, but there is a shortage of buyers. A third reason is the passing of a compulsory act by the Government in connection with the seventh war loan.

A bill known as the wartime profit tax has apparently hit the automotive dealers pretty hard, as it is retroactive for the three years of war which had elapsed before it became law, and thus a trader is taxed to the extent of 50 per cent of his profits over and above 10 per cent of his capital. As this affects profits made up to three years before, profits which have already been distributed in dividends or diverted to the extension of business, the tax is proving onerous to many. In fact, the effort to meet it has tied up operating capital to a considerable extent.

Armistice Affects Prices

Prices of commodities generally started to drop on the signing of the armistice, and the country has not as yet succeeded in reconstructing itself on a pre-war commercial basis.

There are fairly good stocks of the various popular types of American cars throughout Australia—Buick, Chevrolet, Dodge, Hupmobile, Overland, etc., but apparently stocks of other makes are somewhat depleted. The used car market is very flat, owing to the popular belief that prices will drop. It is not anticipated that this state of things will be anything but temporary.

There has been a sufficient supply of tires, although at times the selection of makes has been limited. On the whole, the local rubber factories are able to take care of the demand, and the situation has been improved by importers having cars shipped complete with tires instead of minus tires as before.

There is an ample supply of spare parts for both cars and trucks in the various cities throughout Australia. Occasionally there have been difficulties in shipping these from the United States factories, but in such cases parts have been made locally.

Very successful demonstrations of farm tractors have been held from time to time, and it is anticipated that this branch of the business will develop rapidly as soon as the initial difficulties of arranging distribution are overcome. Unit power and lighting plants are fast finding their way into the country, and the business is generally handled by the electrical supply firms, of which there are many throughout the Commonwealth.

Gasoline Plentiful but High

Gasoline is plentiful, but expensive. The price averages 75 cents an American gallon in the cities. There is also an ample supply of lubricating oil.

One of the reasons why there has been no increase in the price of cars brought about by shortage of supply is that a large percentage of the dealers here find it necessary to dispose of their stocks as quickly as possible in order to get their cash in again and thus keep their total operating capital at the lowest practicable amount. This condition of temporarily tied-up finance is mainly the result of conditions outside the automotive trade, the strain of war taxation and abnormal trading conditions generally.

There is every indication that there will be a big demand for European cars just as soon as any are available. It is not yet known here what European manufacturers may have to offer in the shape of post-war models, but Australians are naturally a British people and therefore are favorably disposed to any British product. Nevertheless it is early to predict what the future may hold in the automobile line, and it is quite obvious that the British or other European manufacturer will have to go a long way to beat the American car builder or to dispossess him of the trade he now holds. There seems to be a reaction in favor of first-class magneto ignition as compared with ignition of battery type.

In conclusion, there is no doubt whatever but that the European car builders are planning extensive and energetically conducted selling campaigns on their after-war products throughout Australia, and it is natural to expect that under the circumstances they will meet with a fair measure of success. Therefore the American car builder must look to his laurels and intensify his sales methods to retain his trade here.

Men of the Industry

Changes in Personnel and Position

R. T. Hodgkins, general sales manager of the Cleveland Tractor Co., was elected a director of that company at a recent meeting of the stockholders and at the directors' meeting following he was chosen vice-president.

Horace N. Trumbull, who was advertising manager for the S K F Ball Bearing Co., Hartford, before he entered the service, has been discharged and has become advertising manager of the Wellman-Seaver-Morgan Co., Cleveland.

W. M. Jones has been appointed eastern sales representative of the Torbensen Axle Co., Cleveland.

E. D. Rogers has joined the staff of the Anderson Motor Co., Rock Hill, S. C., as southwestern district sales manager, with headquarters at Dallas.

A. C. Olfs, formerly eastern representative of the Titanium Bronze Co., has been appointed Michigan representative for the Stewart Mfg. Corp., Chicago, with headquarters in Detroit.

L. B. Cravath has been elected vice-president of the Hessian Tiller & Tractor Corp., Buffalo. He joined the organization as sales manager. He was later made general manager and has recently been chosen a director.

Robert E. Page, for four years assistant foreign sales manager for Dodge Brothers, has joined the staff of the Commerce Motor Car Co. He will look after the Canadian Commerce Truck business.

J. J. Tobias is in charge of the new Detroit branch of the Moto Meter Co., Inc., 2019 Dime Bank Building.

C. H. Williams, formerly manager of the Chicago branch of the Goodyear Tire & Rubber Co., Akron, has been appointed manager of the far eastern division, which covers the Philippines, China, Japan, Java, Siam, India and Eastern Russia.

C. L. Diers, formerly in charge of the Indianapolis branch of the Goodrich Tire & Rubber Co., Akron, is now in charge of the European division, covering Europe, Asiatic Russia and the northern coast of Africa.

W. A. Westlake has been appointed eastern sales manager of the truck tire department of the McGraw Tire & Rubber Co., New York.

W. R. Vogeler, for the past six years export manager of the King Motor Car Co., New York, has been appointed general manager to take the place of E. A. Scheu, who has been made general sales manager.

Bartsch Takes Up Sales and Advertising Reins for Bosch

NEW YORK, Feb. 10—Alfred H. Bartsch has returned to the American Bosch Magneto Co. after an absence of a little more than a year. Effective immediately he takes up the duties of advertising manager, which he surrendered just before this country entered the war, and, in addition, has been appointed the company's general sales manager. Prior to the time he left the old Bosch company, which has since been reorganized, Bartsch was for more than seven years its advertising manager. He left that position to become affiliated with the McLain, Hadden, Simpers Co. advertising agency, and for about a year has made his headquarters in Philadelphia. Henceforth his headquarters will be in New York.

C. J. P. Lucas, Chicago, for the past eight years with the *Automobile Trade Journal*, has resigned, and about April 1 will leave for South America to make a survey of the South American market with a view to establishing a house in Buenos Ayres for carrying an American car, truck and tractor and lines of supplies for Argentina, Paraguay, Uruguay, Brazil and Chile.

Judson M. Sells, until recently general manager of the Northern Steamship Co., has joined the sales force of the Commerce Motor Car Co. in the Buffalo territory.

Harry Moler, Grand Rapids, has quit the theatrical business to sell Willys-Knight and Overland cars.

Honor Blocker has been appointed advertising manager of the Republic Rubber Corp., Youngstown.

F. S. Wright, who has been for many years sales manager of the New York branch of the Valvoline Oil Co., has resigned his position to become connected with the James B. Berry's Sons Co., Inc., Oil City, Pa., as sales manager of this company's New York branch.

F. H. McFarlin has joined the sales department of the Erie Specialty Co., Erie.

Frank Mossberg Joins Rice Leaders

ATTLEBORO, MASS., Feb. 10—The Frank Mossberg Co. has become a member of the Rice Leaders of the World Association.

A. R. Redburn has been appointed sales manager of the truck department of Walden W. Shaw Livery Co., Chicago.

Gustave Huette, Sheboygan, Wis., founder of the Falls Motors Corp., Sheboygan Falls, and for many years president of the company, has disposed of his final interest and retired from all connection with the concern.

R. G. Hayssen, secretary and treasurer of the Sterling Motor Truck Co., Milwaukee, was elevated to the presidency at the annual meeting of the stockholders. He succeeds Victor L. Brown, who has retired from active business. E. M. Sternberg was elected vice-president and Frank Luick secretary and treasurer. The company will devote most of its energy until March 1 to the completion of its government contracts and will then shift to peace business.

E. H. Ruck has been appointed chief engineer of the Automotive Corp., Fort Wayne, and will have charge of all engineering and production. He was formerly with the White Co., and until a few weeks ago was chief engineer of the Cleveland Tractor Co., Cleveland.

George K. O'Donnell has been elected vice-president in charge of the sales of the Coe-Stapley Mfg. Corp., with headquarters in New York City. The New York offices of the company have recently been moved from 135 Broadway to 136 Liberty Street.

John Walter Hertzler has been elected secretary and treasurer of the Pressed & Welded Steel Products Co., Long Island City. He was formerly assistant manager of the Bearings Co. of America, Lancaster, Pa.

J. H. Cooper, formerly vice-president of the Endurance Tire & Rubber Co., has joined the sales force of the Walker Mfg. Co., Racine, as eastern sales manager.

W. B. Stout, formerly of the Packard Motor Car Co., has been appointed sales and advertising manager of the United Aircraft Engineering Corp., New York.

J. J. Buzzell has been appointed advertising manager of the Hyatt Roller Bearing Co., Detroit, to succeed W. E. Biggers, who recently resigned.

J. W. Lever is now district manager of the Denby Motor Truck Co., Detroit. His territory is Oklahoma and Texas.

Capt. Charles Smith, Engineers, U. S. A., who is connected with the Commerce Motor Car Co., has returned from overseas.

A. E. Creeger, identified since its organization with the Nash Motors Co., Kenosha, as special traveling representative, has resigned to become associated with the Ohio Nash Co., in charge of truck sales.

J. I. Case Passes Resolution to Re-employ Returning Men

RACINE, Feb. 7—At a meeting of the Board of Directors of the J. I. Case Plow Works, the following resolution was unanimously adopted:

"Resolved, That all employees of the J. I. Case Plow Works, who left their positions for military service, at home or abroad, will be given re-employment at a compensation at least equal to what they were receiving when they left their positions, provided that such employee desires to return and makes application and reports for duty within thirty days after honorable discharge."

The same policy will be followed by the Wallis Tractor Co.

Briscoe After Foreign Business

JACKSON, Feb. 7—Although running at 50 per cent capacity, the Briscoe Motor Corp. is now producing thirty cars daily. The company plans increasing production constantly until the daily average is between sixty and seventy machines. The 1919 schedule calls for 15,000 cars. This company has established an export office at New York and is preparing to engage extensively in foreign trade.

New G. M. C. Plant at Flint

FLINT, Feb. 8—The General Motors Corp. is to establish a new frame plant here. It will be on a spur line of the Michigan Central Railroad. Such a plant has been contemplated for some time.

Auto Body Co. Speeding Production

LANSING, Feb. 8—The Auto Body Co. has completed a definite schedule of production, which will keep the plant busy for three months. The company is now employing 400 men. Six weeks ago less than 100 men were employed.

Packard Still Filling Government Orders

DETROIT, Feb. 7—No new Packard passenger cars will be ready for distributers before early summer. This company, which was working 100 per cent on Liberty engines and Packard army trucks, is obliged to reorganize completely its plant before passenger car production can be resumed. War contracts are being wound up. The last of the Liberty engines are about to be run through, but there is still a large number of trucks to be made.

No New Columbia Models

DETROIT, Feb. 7—There will be no change in the car models of the Columbia Motors Co. Three models will be produced: The touring at $1,600; the five-passenger Bevel Edge Sport, $1,745, and the sedan, $2,445. The sport model is a new one, having been brought out during the past summer. There will be no cut in prices. The Columbia Co. expects to be in full production by Feb. 15. Its contracts for government trucks, trailers and truck parts are about complete. The company is producing 8 passenger cars daily.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

"Red Star" Bodies in New Building

PHILADELPHIA, Feb. 7—The Lowry Top and Body Co., manufacturer of automobile tops and bodies, specialist for long distance hauling concerns, using bodies from two to six tons and upwards, has moved from 33d and Walnut streets to its new factory at Gaul and Adams streets, in the Kensington district. The company's new quarters allow 70,000 sq. ft. for manufacturing purposes. There are painting, trimming and mill departments on the first floor, and the body-building department proper on the second.

The company is about to produce its newly patented "Red Star" bodies. The patent covers a non-leakable roof, the top construction known as "outside structural member," the general underconstruction and the tail-gate. The patent is especially for the large, covered type of car for intercity hauling. The outside structural member used is of the "waffle-iron" bracing type, of 2-in. oak and is calculated to withstand high pressure both from within and without the top. The raised panel frames prevent accidents to goods within the car, no matter how hard a blow the top may receive. A complete line of these bodies will be carried.

Goodrich Sales Total $123,400,000

AKRON, Feb. 7—The annual report of the B. F. Goodrich Co., made public Saturday, shows net sales amounting to $123,400,000 and net profits $15,500,000, not deducting federal income or excess taxes but after deducting for maintenance, depreciation, bad and doubtful debts. For the year ended Dec. 31, 1917, the net sales of the company amounted to $87,155,072 and the net profits $10,544,677. The directors have authorized a 3½ per cent dividend on preferred stock, half payable April 1 and the rest July 1. They also declared a 1 per cent quarterly dividend on common, payable May 15.

Pierce Governor Erects Addition

ANDERSON, Feb. 7—The Pierce Governor Co. has just completed a two-story brick annex to its factory, giving it an additional 5,000 sq. ft. of floor space. The new building will be used for storing raw material and finished parts. The tool making and pattern making departments will also be moved into it.

Atterbury Doubles Capital

BUFFALO, Feb. 7—The Atterbury Motor Car Co. has increased its capital from $250,000 to $500,000.

Nelson Motor Truck Co. Incorporates

SAGINAW, Feb. 7—The Nelson Motor Truck Co., maker of the Jumbo truck, this week changed from a co-partnership to an incorporation, with a capitalization of $500,000. The officers of the company are: President and general manager, H. B. Nelson; vice-president, J. J. Nelson; secretary and treasurer, C. J. Nelson. The company is making a truck a day, but anticipates producing 1200 machines this year. A new factory addition is under construction and plans for building a complete new plant are being considered for next year.

Telecator in New York Office

NEW YORK, Feb. 7—Herbert H. Scott, president of the Scott Corp., Chicago, manufacturer of the Telecator, an instrument for locating faults in car and truck engines, has opened an office in Aeolian Hall, New York, as a base for Eastern business. This office will be in charge of Guy Rickenbaugh. The Telecator is the invention of Mr. Scott, and is made in two models, one for attachment to the dash where it also acts as a lock for the car, and the other a portable instrument for use in garages. The total output of the company so far has been supplied to the Government.

Monroe Plant to House Moline Engines

PONTIAC, Feb. 8—The plant and property of the Monroe Motor Co., which was sold recently for $75,000 to the Wilson Foundry & Machine Co., will be used for the production and assembly of engines for the Moline Tractor Co. All Moline engine parts will be made either in the present Wilson plant or in the new plant. About 500 men will be employed. First deliveries will be made in April.

General Motors Buys in Canada

DETROIT, Feb. 10—The General Motors Corp. has purchased a 37-acre factory site in Windsor, Ont. General Motors officials will make no statement regarding the proposed Canadian activities of their organization.

Defiance Plant Quits War Work

DEFIANCE, Feb. 7—The Defiance Machine Works, which has been on a 100 per cent war basis, has voluntarily discontinued its contract for the manufacture of big guns for the Government. It is intended to save the Government further expense in operating this plant and enable the management to readjust the factory for handling peace-time business.

Overland Speeding Up Production

TOLEDO, Feb. 10—The Willys-Overland Co. has increased its daily production for February to 400 cars. During January the plant's daily average was 320 finished jobs. Odds and ends of war work are being cleaned up and reconstruction is about complete. The company is now operating at two-thirds capacity. It will be July at least before full production of 600 cars daily will be obtained.

Canadian Chalmers to Make 2000 Cars

WINDSOR, ONT., Feb. 8—The Chalmers Motor Co. of Canada, Ltd., will produce 2000 cars this year. The company, which is turning out 10 cars daily, contemplates no price reduction, and is guaranteeing its dealers against such a move.

Canadian Maxwell Plans 6000 This Year

WINDSOR, ONT., Feb. 8—Approximately 6000 cars will be made by the Maxwell Motor Co. of Canada, Ltd., during 1919. The 1919 Canadian Maxwell has a different style top than the 1918 model, demountable rims instead of wheels, a Johnson carbureter with vacuum feed and a gasoline tank on the rear. The company anticipates no price reduction and is protecting its dealers. It is producing 25 cars daily, but will increase the output in June.

Annual Meeting of Detroit Steel Products Co.

DETROIT, Feb. 10—The Detroit Steel Products Co., at its annual meeting, elected the following officers: President, John G. Rumney; vice-president and general manager, Victor F. Dewey; secretary, H. F. Wardwell; treasurer, E. R. Ailes; assistant general manager, Mason P. Rumney; production manager, A. L. Baldwin.

B. R. & L. Co. Changes Officers

CLEVELAND, Feb. 10—The Baker R. & L. Co., makers of Rauch & Lang electrics, Owen Magnetic gasoline cars and B. R. & L. Electric industrial trucks and tractors, has made several changes among its administrative staff. C. L. F. Wieber has resigned as president and is now acting as chairman of the board. Fred R. White, previously vice-president and in charge of production, is now president. E. J. Bartlett, previously manager of the commercial department, is now vice-president and general manager. R. M. Owen and D. C. Durland remain as vice-presidents of the company. Robert C. Norton remains as treasurer, but for some time has been in France as a major of artillery. His active duties are being performed by W. P. Southward, assistant treasurer. F. W. Treadway remains secretary and counsel of the company.

The company, which is now running about ten cars daily, expects to increase its production of industrial trucks and custom bodies and to continue its other products on the present scale. Manufacture of 4000 cars is contemplated in 1919. The largest production increase will be in the body department and in industrial trucks.

20,000 Sq. Ft. for Ahlberg Bearings

CHICAGO, Feb. 10—Owing to the government ban on building operations during the war, the Ahlberg Bearing Co. had to wait until this time to commence work on its new plant at 29th Street and Calumet Avenue. Operations have already been started and it is expected that the new factory will be ready for occupancy the latter part of February. The new building will be two stories, of steel and reinforced concrete, with a floor space of about 20,000 sq. ft. The lighting has been so designed that every part of the building will be available for the handling of the remaking process. Provisions have been made for a hardening plant also. The first floor will contain the salesroom, stock room and shop. The executive and general offices will occupy the second floor, and a garage will be erected in the rear.

General Motors to Build for Scripps-Booth

DETROIT, Feb. 10—The General Motors Corp., which recently gained control of the Scripps-Booth Corp., will establish that company in a new $1,500,000 factory building as soon as a suitable site can be obtained. The proposed plant will have a capacity of 25,000 cars annually. In the present establishment the Scripps-Booth organization is cramped for room. Unlike most other automobile concerns, this company was not seriously affected by the sudden ending of the war inasmuch as it was not engaged very extensively in Government work.

The company is making twenty cars daily, but in February it expects to boost production to thirty cars. While 5500 machines were built last year, the 1919 schedule calls for the manufacture of 10,000. The 1919 Scripps-Booth models are the same as last year, with the exception of several small changes in detail and in color.

Gier Steel Profit $427,903

LANSING, Mich., Feb. 10—The newly elected Board of Directors of the Gier Pressed Steel Co. held its election following the annual meeting of the company, Wednesday, Jan. 22, and named B. S. Gier, president and general manager; W. H. Newbrough, vice-president, and D. F. Edwards, secretary and treasurer. W. K. Prudden was elected chairman of the board. The new board is composed of the officers and H. F. Harper, Edward Ver Linden and Arthur D. Baker. The annual financial statement shows an operating profit of $427,903.03, or 55 per cent of the outstanding stock. This is double that of 1917. The estimated Federal tax on this year's operations is $290,000, or 68 per cent of the total profit. The surplus on Dec. 31, 1917, plus the net income for operations makes a total of $638,200.82. Out of this comes the estimated Federal tax, leaving $347,200.82. From this is deducted $156,250, the stock dividend declared Jan. 15, 1918, and the cash dividend of 5 per cent or $39,062.50 of Dec. 13, 1918, leaving an extended total of $151,888.32.

Dividends Declared

Grant Motor Car Corp., Cleveland, 1 per cent, common, payable March 1 to stockholders of record Feb. 18; 1¾ per cent, preferred, payable Feb. 1 to stockholders of record Jan. 20.

Reorganize United Brass & Aluminum

PORT HURON, Feb. 10—The United Brass & Aluminum Mfg. Co. has been reorganized with the following officers: President, Jacob Goldman; vice-president, H. S. Grant; secretary and treasurer, Shirley Stewart, and Albert Ryan general manager. This concern was formerly the William O. Lee Co. The plant has been extended and is now making brass bushing for the Packard, Northway Motors Co. and a number of other automotive concerns.

Boring Tractor's New Plant

ROCKFORD, Feb. 10—The Boring Tractor Corp. has purchased six acres of land and will erect a new plant on this tract. The tracks of three railroads are located close to the new site, giving excellent transportation facilities. It is hoped to have the first unit of the new series of buildings ready by May 1. Reinforced concrete will be utilized in the construction.

Melling Forge Co. Elects New Officers

LANSING, Feb. 10—The Melling Forge Co. at its annual meeting elected the following officers: President, J. B. Simon; vice-president and general manager, George Melling; secretary and treasurer, J. B. Whitney. The company was organized in March, 1917. During the year machinery and equipment have been doubled and the working force increased 150 per cent. Ninety-five per cent of the output of this plant has been Government work, but contracts with the Olds Motor Works and the American Car and Foundry Co. have already been placed for 1919.

Grant Motors Gains $450,000 in Year

CLEVELAND, Feb. 10—The net earnings of the Grant Motor Car Corp. for the year ended Dec. 31 were in excess of $450,000, after paying the preferred dividends, which left a balance of more than 20 per cent on common stock.

Chevrolet Will Expand

DETROIT, Feb. 10—The Chevrolet Motor Co. plans to expand its factory at Toledo to a $4,000,000 or $5,000,000 plant within two years, according to T. W. Warner of the Toledo-Chevrolet Motor Co. Additional property of approximately five acres has been purchased for new buildings. The plant has been employing 1200 men, and it is expected that from 3000 to 4000 will be employed when the new additions are complete.

U. S. Pressed Steel Co. Enlarges Plant

YPSILANTI, Feb. 10—The U. S. Pressed Steel Co. has greatly enlarged its plant here. It has installed the conveyer system, and is now making steel products for tractor concerns. Among its contracts are seats for Fordson and Samson tractors.

Calendar

ENGINEERING

S. A. E. Meetings

March 5 — Minneapolis Section, S. A. E.—Hotel Radisson. "Tractor Service and Sales."

April 2—Minneapolis Section, S. A. E. — Hotel Radisson. "Implements Designed for Tractor Belt Power and Their Characteristics."

MOTOR SHOWS

Feb. 6-15—San Francisco, Cal. Third Annual Pacific Automobile Show, Motor Car Dealers' Assn. of San Francisco, Exposition Auditorium. G. A. Wahlgreen, Manager.

Feb. 10-15 — Rochester, N. Y. Rochester Automobile Trades Assn., Exposition Park. George C. Donahue, Manager.

Feb. 12-15—Defiance, O. Second Annual Show under auspices of Defiance Automobile Dealers' Assn.

Feb. 15-22—Newark, N. J. N. J. Auto Exhibition Co. Calude Holgate, Manager.

Feb. 15-22 — Cleveland, Ohio. Cleveland Auto Show Co. Fred H. Caley, Manager.

Feb. 15-22—Minneapolis, Minn. Minneapolis Auto Trade Assn. Walter B. Wilmot, Manager.

Feb. 15-22—Albany, N. Y., Albany Automobile Dealers' Assn. State Armory.

Feb. 16-22—Waco, Tex. Henry B. Marks, Manager.

Feb. 17-22—St. Louis. St. Louis Auto Mnfrs. & Dealers' Assn. Robert E. Lee, Manager.

Feb. 17-22 — Louisville, Ky. Louisville Auto Dealers' Assn.

Feb. 17-22—Des Moines, Iowa. Tenth Annual, Des Moines Automobile Dealers' Assn. C. G. Van Vliet, Manager.

Feb. 17-22 — Pittsfield, Mass. Pittsfield Automobile Dealers' Assn., State Armory. James J. Callahan, Manager.

Feb. 17-22 — Passenger Cars; Feb. 24-27, Trucks—South Bethlehem, Pa. Lehigh Valley Auto Shows Co. J. L. Elliott, Manager.

Feb. 17-22—Grand Rapids, Mich. Grand Rapids Automobile Business Assn. E. T. Conlon, Manager.

Feb. 17-22—Seattle, Wash. Cars, Motor Car Dealers' Assn., State Armory. A. G. Schaeffer, Manager.

Feb. 18-22—Baltimore, Md. Baltimore Automobile Dealers' Assn. and Automobile Club of Maryland, Fifth Regiment Armory. H. M. Lucius, General Manager.

Feb. 18-22— Oklahoma City, Okla. Automotive Show. R. H. Haun, Manager.

Feb. 18-22—Wichita, Kan.

Feb. 19-22 — Evansville, Ind. Cars, Evansville Automobile Dealers' Assn. Coliseum.

Feb. 22-March 1 — Hartford, Conn. Hartford Automobile Dealers' Assn., Inc., Broad Street Armory. Ben F. Smith, Manager.

Feb. 22-March 1—Atlantic City, N. J. Auto Trades Assn. of Atlantic City.

Feb. 22-March 1—New Castle, Pa., Lawrence County Association of Automobile and Accessory Dealers.

Feb. 23-March 1—Cedar Rapids. Auditorium, Automobile Dealers' Assn.

Feb. 24-March 1—Burlington, Ia. Second Annual.

Feb. 24-March 1—Kansas City, Mo.—Kansas City Motor Dealers' Assn. E. E. Peake, Manager.

Feb. 24-March 1—Springfield, Mass. Automobile Dealers' Assn. Harry W. Stacy, Manager.

Feb. 24-March 1—Springfield, O.

Feb. 24-March 1—Portland, Ore. Ninth Annual Dealers' Motor Car Assn., Automobile Palace. M. O. Wilkins, Manager.

Feb. 24-March 1—Duluth, Minn.

Feb. 25-March 1 — Erie, Pa., United States Garage.

Feb. 26-March 1—Mason City, Ia. Fifth Annual, Mason City Auto Show Assn.

Feb. 26-March 1—Madison, Wis. Seventh Annual, Automobile Dealers' Division of Madison Assn. of Commerce, Union Transfer Bldg.

Feb. 26-March 1—Quincy, Ill. Cars, Quincy Automobile Trade Assn. Armory.

Feb. —Wheeling, W. Va. Automobile Show at Market Auditorium.

March 1-15—New York Aeronautical Exhibition, Manufacturers' Aircraft Assn., Madison Square Garden and 69th Regiment Armory.

March — Scranton, Pa. Thirteenth Regiment Armory, Scranton Automobile Assn.

March—Utica, N. Y. Utica Motor Dealers' Assn. W. W. Garabrandt, Manager.

March—Philadelphia, Pa. Philadelphia Automobile Trade Assn. Passenger cars.

March 1-8—Detroit, Mich. Detroit Automobile Dealers' Assn. H. H. Shuart, Manager.

March 3-5—Quincy, Ill. Trucks and Tractors. Armory.

March 3-8—Columbus, O. Columbus Automobile Show Co., Memorial Building. W. W. Freeman, Manager.

March 3-8 — Muskegon, Mich. Third Annual, Armory, Muskegon Lodge No. 274, B. P. O. E. John C. Fowler and George M. Friant, Managers.

March 3-8—Scranton, Pa. Ninth Annual, 13th Regiment Armory, Scranton Automobile Assn. Hugh B. Andrews, Manager.

March 3-8—Buffalo, N. Y. Buffalo Automobile Dealers' Assn.

March 5-8—Lancaster, Pa. Automobile Trade Assn., Rowe Motor Co.'s Bldg. R. W. Shreiner, Manager.

March 8-15 — New Brunswick, N. J. Armory, New Brunswick Motor Trade Assn. William Kuehle, Manager.

March 10-15—Paterson, N. J. Paterson Automobile Trade Assn., Fifth Regiment Armory. H. MacGinley, Show Manager.

March 10-15—Syracuse, N. Y. Syracuse Automobile Dealers' Assn. Harry T. Gradner, Manager.

March 10-15 — Omaha, Neb. Fourteenth Annual, Omaha Automobile Trade Assn., Auditorium. Clark G. Powell, Manager.

March 15-22 — Boston, Mass. Boston Automobile Dealers' Assn. Passenger cars only. Chester I. Campbell, Manager.

March 15-22—Harrisburg, Pa. Harrisburg Motor Dealers' Assn., Overland Warehouse. J. Clyde Myton, Manager.

March 17 - 22 — Great Falls, Mont. Montana Automobile Distributors' Assn.

March 19-22—St. Joseph, Mo. St. Joseph Automobile Show Assn., Auditorium. John Albus, Manager.

March 19-22—Norfolk, Neb. Norfolk Automobile Show Assn.

March 22-29—Pittsburgh Automobile Dealers' Assn. of Pittsburgh. John J. Bell, Manager.

March 22-29—Passenger Cars. April 1-5—Trucks, Brooklyn. Brooklyn Motor Vehicle Dealers' Assn. I. C. Kirkman, Manager.

March 24-29—Greenfield, Mass. Greenfield Automobile Dealers' Assn., State Armory. James J. Callahan (Pittsfield) Manager.

March 24-29—New Orleans, La. Henry B. Marks, Manager.

March 24-29—Utica, N. Y. Utica Motor Dealers' Assn.

March 26-29—Watertown, N. Y. Tenth Annual, State Armory, Automobile Dealers, Inc. Arthur E. Sherwood, Manager.

Third week March—Trenton, N. J. Trenton Auto Trade Assn. John L. Brock, Manager.

April 5-12—Montreal, Can.—National Motor Show of Eastern Canada, Victoria Rink. T. C. Kirby, Manager.

April 13-19—Bristol, Tenn. Cars, trucks, tractors, airplanes and accessories. Bristol Chamber of Commerce.

Not decided—Bridgeport, Conn. Auspices of City Battalion. B. B. Steiber, Manager.

Not decided—Indianapolis, Ind. Indianapolis Auto Trade Assn. John B. Orman, Manager.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

TRACTOR SHOWS

Feb. 15-22—Minneapolis, Minn.

Feb. 18-22—Wichita, Kan. Annual Mid-west Tractor and Thresher Show, Wichita Tractor and Threshing Club. Forum.

Feb. 24-March 1—Kansas City, Mo. Fourth Annual Tractor Show. Sweeney Building, Kansas City Tractor Club. Guy H. Hall, Sec.

RACES

March 15—Santa Monica, Cal. Speedway.

May 17—Uniontown, Pa., probably 112½ miles.

July 5—Cincinnati, O., Speedway.

CONVENTIONS

Feb. 19—New York, 13th annual banquet of Aero Club of America, Waldorf-Astoria.

Feb. 25-28—New York. Sixteenth Annual Convention. American Road Builders' Assn.

Feb. 25-28 — Ninth American Good Roads Congress and 16th Annual Convention of the American Road Builders' Assn. Hotel McAlpin, New York.

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

Improvements in New Mitchell

CHICAGO, Feb. 8—The new Victory model Mitchell on exhibition for the first time at the showrooms on Michigan Avenue has been entirely remodeled. The body lines have been improved by a bevel edge, while upholstery, top and other appointments are superior to the pre-war light six. A thermostat now controls the temperature of water, intake gases and air. The new car has a 120-in. wheelbase, using tires 34 x 4, and powered with a 3¼ x 5-in. engine. Some of the major improvements consist of a deeper frame, stronger rear axle, better brake layout and ball-bearing steering gear. The new crankshaft shows 35 per cent increased tensile strength. The long cantilever springs of last year have been retained. The new model sells for $1,475 f.o.b. Racine, and comes in a five-passenger touring and three-passenger roadster, both at the same price. The standard finish is green with black hood and fenders.

New Manufacturers' Representative

CHICAGO, Feb. 10—The Miller-Cave Corp. has opened offices in the People's Gas Building, Chicago, for service to manufacturers as sales representative to the automotive industry.

Franklin A. Miller, president and general manager, was with the Stromberg Carbureter Co. for several years in the sales department and later as advertising manager. For the past four years he has been connected with the western advertising department of the Cosmopolitan. Robert R. Cave, vice-president, has recently returned from the Government service as a divisional procurement officer. C. E. Sedweek, secretary and treasurer, has also just returned from a captaincy in the Army Transport Division.

Wright-Martin Turns Out Combination Liberty-Hispano-Suiza

NEW BRUNSWICK, Feb. 10—About 2000 workmen are still employed by the Wright-Martin Aircraft Corp. on a Government airplane engine contract, which will be completed in about a month. It has developed an airplane motor combination of Liberty-Hispano-Suiza, and has a four- and six-cylinder engine completed.

European Expansion Under War Pressure

Manufacturers Unprepared for Peace Conversion—Merchandising Organizations Disrupted—Government Financing and Designing Ended with Armistice—Knowledge of Production, But Without Design and Finance

PART II

By David Beecroft

LONDON, England, Jan. 21—It is not surprising that after 4½ years of war many of the British and Continental manufacturers find themselves unprepared for quick conversion onto a peace basis. Some of these factory organizations resemble a person who has unexpectedly been knocked down by a vehicle whose approach was not noticed. While in this predicament the first impulse is for help and protection. So with these factories; not having the future clearly mapped out and having during the war suffered a complete destruction of its entire merchandising organization, the first impulse is a negative as contrasted with a positive course.

The reason for this is quite fundamental.

One manufacturing magnate has said that successful business is made up of four cardinal activities: a—designing, b—production, c—financing, d—merchandising. The correct proportioning and synchronizing of these four is the essential of success. With the British makers during 4 to 5 years of war only one of these four has received attention, namely, production. But not so with designing. The Government has looked after that; at least it has been done by some one outside of the factory in which the job was manufactured and the factory owner has had all the finance handled for him. The Government has handled it. He has never had to give scarcely a moment's consideration to it. So with merchandising. The Government has been the only customer, and selling and production have become as inactive as designing and financing the job.

Thus has the British manufacturer largely, under war, gone through a spoon-feeding production. He has seen his factory double, triple, quadruple and in some cases, increase tenfold. He has seen unheard of increases in production and he has for four to five years watched almost the complete disintegration of his selling organization both at home and abroad.

Thus we see these manufacturers to-day having to take up three activities which from four to five years have been crippled by the Government. It is not to be wondered that after the thunderbolt at noonday of November 11 a period of indecision

should set in and that with Christmas days ahead that indecision should prolong itself, with elections aiding in this delay.

This may explain why five post-war models are ready, why five post-war model prices had been set and why plans for the future are not crystallized as many might expect. But while picking up the three activities of design, finance and merchandising, which had remained dormant during the war, is a task of no mean magnitude, the British maker is confronted with other problems that are giving him perhaps greater concern. To-day he finds himself at the forks in the road. To his right lies the new highway for increased production, which looms into new importance because of the large modern factories filled with modern machinery that he finds himself in possession of as a result of the war.

To the left is the long trodden and more familiar road of low production and high price of the article coupled with wide variation in design, multiplicity of models and old design developed as a result of low production methods.

Which course to select is a problem of marked stature to the maker, who is yet hedged round with the smoke of battle and the never-ending demand of daily increasing production of munitions of war.

Must Change Manufacture Radically

To decide as to which fork in the road to take is made harder by the withdrawal of the strong arm of the Government. From now on the factory must carry along all four activities, design, production, finance and merchandising. Many factories had not sufficiently weighed each of the four. Some are weak-hearted. They want to go into quantity production but are weak-kneed. They are afraid they cannot merchandise them. Their old selling prices are gone. New ones had to be built up and 4 years of war has entirely eliminated the merchandising factor and it will be hard to rebuild.

Design for quantity production is a stumbling block to many. From 4 to 5 years their engineers in some cases had been on special war work, and they had not followed very closely what has been done. It is not surprising when thus halting at the fork in the road and in the throes of such a mental chaos that positive action should seem slow, if not naturally wanting and that the negative action should seem to dominate with not a few concerns.

To enter whole-heartedly into quantity production called for a radical change in British motor car manufacturing methods. It calls for a complete discontinuance of the old method of pre-war days—those days of Olympia expositions when the maker took to Olympia his new model to see how it caught the public eye and to see how many orders he could get, how much deposit money he could bring home and so, when the show was over, completely revise and design the job and start manufacturing. That was a sure-game policy. There was no losing on it. But that was not quantity production. It did not contain a single fundamental of quantity production.

Bold Program Needed

A few of these same sure-game managers are in charge of factories. True the factories are new. True they are modern factories. True the Ministry of Munitions has had production in them, but this does not insure a quantity production program in car manufacturing.

Quantity production calls for a bolder program than the average British manufacturer has attempted in the past. It calls for a complete reversal of attack. It presupposes a mental change as well as changes in manufacturing processes.

The question of the moment is can the British maker convert himself to the new quantity program?

British Factories Ideally Equipped

Notwithstanding the handicaps which the British manufacturer is under because of the war, he has the advantage of greatly increased factors. These invariably are of the very last word in modern construction, and are permanent, as everything of the kind is in Great Britain. Buildings are invariably brick, generally of the one-story type with saw-tooth roof construction, and have very large rooms. Everything necessary in the way of good lighting, good arrangement of machinery, central heating, forced ventilation, canteens at which the great majority of employees can get cheap noon-day meals, Red Cross facilities, with resident doctor and corps of nurses, auditoriums for entertainments, technical libraries, educational classes, in fact everything that could be asked for in connection with British factories exists.

While many of these additions are recent, not a few of them were made about the middle of the war, so that the companies have been using these factories at capacity for two years, and in some cases longer.

Rolls-Royce is a typical example of British factory expansion under the war. This factory has been required to manufacture only aircraft engines. Before the war it had 3000 employees and on Nov. 11 it had 8000. The factory covered 11 acres. The new buildings were erected on an orderly basis, and were filled with the finest machinery possible to obtain. When the armistice was signed the company was producing upward of 80 aircraft engines per week, mostly of the Eagle and Falcon models. It had started production on the large Condor twelve-cylinder type with cylinders 6½ by 7½.

Such a firm had little opportunity of making any progress on its post-war models because of Government control, and it will be engaged on aircraft work for some months to come. Its post-war program consists largely of carrying on its pre-war model, the 40-50-hp. six-cylinder chassis. There are many rumors of a small six-cylinder chassis of 15.9 hp., but these could not be confirmed.

Increased Organization Nearly 1000 Per Cent

One of the companies to make perhaps unprecedented progress during the war is Austin of Birmingham, which previous to July, 1914, had 2500 employees, but now has 22,000, or had this number on armistice day. The factory buildings are situated well in the country in Northfield, which is a suburb of Birmingham. This company during the war has had a variety of activities. It delivered 2000 airplanes, 2000 motor trucks, 350 armored cars, 650 guns, 750 touring cars, 148 ambulances, but by far its greatest reputation was made in its shell manufacture. In this work it reduced the price of the 9.5-in. shell from approximately $62.50 to $31. In other words, it cut it in half. The reduction in cost was of such importance that the matter was brought up in Parliament and an explanation of how it was possible to accomplish such results was made. Being located in the country it has been necessary for the Austin company to have special trains to bring its 22,000 workers from the surrounding locality. The railroads carried 10,500 of these workers to the plant in a period of 85 min. The company

has lines of motor buses which cover many of the adjacent areas.

Factory buildings cover 53 acres, and it has been necessary to feed 20,000 of the workers at the factory. This has called for a tremendous canteen organization.

Austin was one of the few companies fortunate in being able to develop its post-war model.

Maintains Technical Institute for Employees

This factory literally abounds with activities for the benefit of the workers. There is a technical society with a membership of 750 which holds regular meetings and has a technical library of over 500 volumes. The company has accommodation for 10,000 bicycles used by its employees. There is a large factory farm on which much of the produce for the canteen was grown. At a company grocery store it has been possible to supply provisions at a low price which were difficult to obtain. There is a technical institute for the education of the factory apprentices, who are given time during their working hours to take educational courses.

Another British factory which can be looked upon very largely as a war plant is the Siddeley at Coventry. On armistice day this factory was employing 5000 to 6000 workers and had 20 acres of floor space. It was delivering 150 airplane engines per week and twenty complete planes. With each of these went a 50 per cent stock of spares, which gave a considerable war output. The Siddeley factory is as modern a plant as could be found. The buildings are all of brick construction, largely one-story design, with a few multi-story buildings. Light, heating and ventilation are the best that can be found in any country. All buildings are fitted with modern machinery, much of which is American. The Siddeley company gives promise of being one of the aggressive British manufacturers in car production, and, while the company's plans are not definitely worked out, it has two thoughts primarily in mind—first, the production of a good car in quantity, and second, the merchandising of it at a low price.

Continue to Build Aircraft Engines

This company, like other British companies, has had great experience in manufacturing aircraft engines. It was one of the first to manufacture the twelve-cylinder air-cooled V-type R.A.F. which has had such wide use in the Royal Air Force. Siddeley took the drawings of this engine in December, 1914, and had the first engine made in March, 1915. In addition to manufacturing this engine, Siddeley has manufactured his own vertical six-cylinder design. It is stated that 25 per cent of all the British engines at the front were made by the Siddeley company. The Lanchester firm, one of the pioneers in Great Britain, has been engaged almost exclusively on aircraft production. It has been manufacturing the Arab Sunbeam model, an eight-cylinder design which has been produced in great quantities. In addition Lanchester has built other aircraft engines and expects to be engaged on this work for many months yet. During the war it built many of the air-cooled R.A.F. types.

The Sunbeam company was required by the Government to devote all of its attention during the war to the development and production of aircraft engines, and although the Sunbeam automobile was used as a staff car, the company was not permitted to build it in order that all of its activity might be devoted to aircraft work. Previous to 1914 the Sunbeam company had gone perhaps as far as any British concern in the development of aircraft engines, and it was because of this preliminary work that the Government practically assumed complete direction of the factory. Since the starting of the war 27 different types of aircraft engines have been developed for various uses, such as airplanes, seaplanes, blimps, dirigibles, flying boats, etc. Several of these engine types have been developed for certain types of machines, such as the flying boat for Russia. The company has 4000 workers, and has capacity for 4000 automobiles per year or approximately 80 per week. The factory has not developed as extensively as many other factories during the war largely because it has been used more as a development factory than a production one.

Vauxhall is another company that has made great development during the war, and many factory additions have taken place. The company is relatively small, with 1800 workers at the end of the war. It was largely engaged on the manufacture of Vauxhall cars throughout the war and so suffered very little disorganization. Because of this the company was able to develop its new four-cylinder valve-in-the-head car, which is one of the few British post-war models. The company does not contemplate going ahead rapidly on this model, which is designated as the 30-98 type, and plans only 50 of them for this year. It has a speed of 80 to 90 m.p.h. on the level, and travels 25 miles to the gallon at 33 m.p.h. with a four-seated body which weighs 2464 lb. The cylinders are 98 x 150 millimeters.

L. H. Pomeroy, the Vauxhall engineer, shares with many British engineers the opinion that designing an airplane engine is child's play compared with the automobile line. Many of them think that one Grand Prize road race gives them more information on engines than four years of war.

Crossley Output 250 Cars Monthly

The Crossley is a typical example of the growth under war pressure of one of the old British manufacturers. Before the war it had 500 employees, and on Nov. 11 it had 5000. Its capacity of fifty cars per week before the war has increased to 250 per week now. Before the war the old factory had 2½ acres of floor space and now it is 9 acres. In addition the company has one of the largest aircraft factories in England, which was completed about the middle of 1918. It covers 23 acres and is located in the outskirts of Manchester, or approximately 3 miles from the old factory. The erection of this factory was one of the building accomplishments of the war. In December the company was devoting one-third of its manufacturing effort in its old factory to airplane engines and two-thirds to motor cars. Two types of engines were in production, the six-cylinder Beardmore and the British air-cooled B.R. 2, a rotary type of engine. Just before the armistice the factory started on the manufacture of a third type of aircraft engine.

In the early days of the war—in fact, as far back as 1912, when the British Government organized the Royal Flying Corps, which later became the Royal Air Force—it was decided to use the Crossley chassis as the motor vehicle best suited for a good deal of the aircraft work, and when war broke out 100 of these were ready for the work. This was followed by Government orders to produce as many as possible. In the early days of the war these were produced at the rate of 30 per month and in the final days at 250 per month.

Made Tractors, Guns, Trucks, Airplane Engines

Renault, for example, has been manufacturing his heavy tractors for moving guns; he has been manufacturing cars; he developed the small Renault tank, and was producing it at the rate of 20 per day in December; he was manufacturing large guns com-

plete; he was manufacturing motor truck types of axles and running gears for guns; he had built an entirely new aircraft factory for the manufacture of planes; and he was manufacturing different types of aircraft engines.

With all this variety of war program it was quite impossible to install modern production methods on each and all. Notwithstanding this he had in operation one of the best systems of aircraft assembly in Europe. He was assembling the small tanks on a production progressive assembly basis, using the traveling chain method.

These tanks were traveling steadily along an assembly platform and the work on them was being carried on as they progressed. The war had required the opening up of new foundries which were constantly enlarged from time to time. So it was with all the other departments of the factory. There was never any time when each had reached its state of completion. It was a constant program of expansion, with no thought of terminating it until the morning of Nov. 11.

No Halt to Expansion

The development in other French factories was on a par. The case in question is that of the Gnome company manufacturing the Gnome and LaRhone engines in Paris. This company, previous to the war, had 500 employees. In December it was working with 4,000. The entire force was on aviation engines.

The company was producing thirty-five per day and was building four models of the Gnome alone. It had been asked by the government to build 350 of the Salmson radial type engine which has been such a successful war product.

The company has two large Paris factories and had partly completed a large foundry, part of which was in operation and had just completed the building for a very large forge shop. Some of the hammers had just been moved into the building and the work of installation was just started.

In the design and layout of these new buildings there was only the thought that the government must have more engines from this company no matter what the cost or what the possibilities of using these factories should the war unexpectedly stop. The work of equipping them was going ahead in December. Besides this, great additions to the factories for machine shops and assembly rooms were in the course of erection. The factory is a fine brick structure modern to the last chapter of factory design and equipped with all the modern machinery that aircraft engine manufacture called for. The company had manufactured many of its own lathes which were in use. Long rows of American machinery were seen alongside of French, British and Italian machinery.

800 Aviation Engines a Month

The company was going ahead on a war program developing its 800 hp. twenty-cylinder radial type engine, with fixed cylinders as compared with the rotary type engine which this company has always manufactured. The fixed cylinders were arranged in four circles of five cylinders to the circle. The circles were placed one behind the other so that each group of five cylinders was working on a single throw of the crankshaft. The job is water-cooled which represented a new departure in Gnome practice. Also under development was the new 500 hp. Salmson radial engine which the company was aiding in the development of at the request of the government.

Another French firm, Lorraine-Dietrich, made amazing development during the war. Its factory area has been more than doubled and it has been producing aviation engines at the rate of 800 per month. This is one of the old French automobile concerns which very early began the development of aircraft engines and which is to-day looking into the future and preparing for the possibilities of commercial aviation. Its factory additions have been carried out on a broad practical basis rather than in a step by step piecemeal topsy-turvy way.

The factory has enormously large rooms for machine shops, assembly, etc. They compare with the largest manufacturing floors in America. The machinery is all laid out in a well organized way, but there is a lack of electric industrial trucks to facilitate in removal of the material. The company is one example of the many that have endeavored to secure such equipment during the last year or two.

This company has been carrying through a large airplane program and its final thought is indicated in the development of a twenty-four-cylinder, 1000 hp. W-type of engine that should be well suited for commercial work. There are three rows of cylinders, the center row mounted vertically, and a row at each side, inclined slightly above the horizontal. All three groups work on the one crankshaft. The company has been producing an eight-cylinder V-shape 275 hp. with cylinders mounted at 90 deg. It has also been producing a twelve-cylinder 400 hp. type with cylinders at 60 deg. and a twelve-cylinder 600 hp. type with cylinders at 60 deg. The 600 hp. type uses four calves per cylinder, whereas the others have two. The 1000 hp. type uses the same cylinders with four valves as used in the 600. The company has also been producing aviation engines of 220 and 300 hp. so that it has been in production in five different models and has the sixth under development.

Expansion Constant at Panhards

The pioneer firm of Panhard-Levassor is an example of a French maker that has had a large production on four-wheel drive tractors for artillery use and has also manufactured trucks, aviation engines, ammunition, and other lines of war products. The company developed one of its own types of aviation engines which did not develop as satisfactorily as expected and many of which are now used in motor boats. In December it was just completing its government contracts for shells. The factory was in a complete state of expansion. It was one of the few French factories located within the walls of the city placed as it is close to the wall on the South. It has just completed a large three-story foundry of brick and reinforced concrete construction. The lower floor only has been put into operation. The elevators and staircases were just being installed. Panhard has added one of the finest three-story office buildings that exists in Europe. It stands as a monument of the development of the industry under war pressure. The building is largely completed. Adjacent to it are lines of new factory buildings which are just nearing completion. These factory additions are laid out on a modern scale giving large machining rooms as well as assembly floors. A general use of underground tunnels for transportation between buildings is a recently developed feature of the factories. During the war it was necessary for Panhard to utilize every adjacent building in its factory zone. Three and four-story warehouses were converted into machine shops for manufacturing shells. Alleys and every available outside space was utilized for storage of war products. Panhard's work of expansion was really just under way.

Ricardo Engine "Made Good" in Tanks

Embodies an Unconventional Piston Design and Means for Cooling the Piston, for Preheating the Carbureter Air and for Preventing Any Unvaporized Fuel That Gets by the Piston from Getting Into the Crank Chamber

THE war has brought a new type of internal combustion engine prominently to the front in England. It is the Ricardo engine, which was used successfully in British tanks during the last year of the struggle to the number of about 3000. This engine incorporates means tending toward the more economical use of fuel as well as toward a saving in lubricating oil. The outstanding feature of the Ricardo engine is its piston design. This piston is of the double diameter type, to use a term which has become somewhat familiar in connection with two-stroke engines. But in the Ricardo piston the lower portion is of smaller diameter than the upper, and serves chiefly the purpose of a crosshead, while the upper part carries the piston rings and serves to seal the combustion chamber. The lower part of the piston works in a crosshead guide, which is a sleeve of less diameter than the cylinder and fitted into the lower end of the cylinder in such a way as to project into the crankcase. The large diameter top part of the piston is rigidly connected with the smaller diameter lower or crosshead part by a long tube cast integral with the top part. At its lower end this tube carries the crosshead sleeve, which is a sliding fit in the crosshead guide. The wrist pin is carried in the the crosshead at the bottom, the conventional type of connecting rod being used. The diameter of the tube connecting the top and bottom of the piston is little more than one-half of the cylinder diameter.

Many reasons are advanced for the adoption of this design, and results with the engine in tanks bear out practically all of these claims. The primary object is to get a piston in which the upper part with the rings is entirely free from side pressure and only takes the explosion pressure on its head.

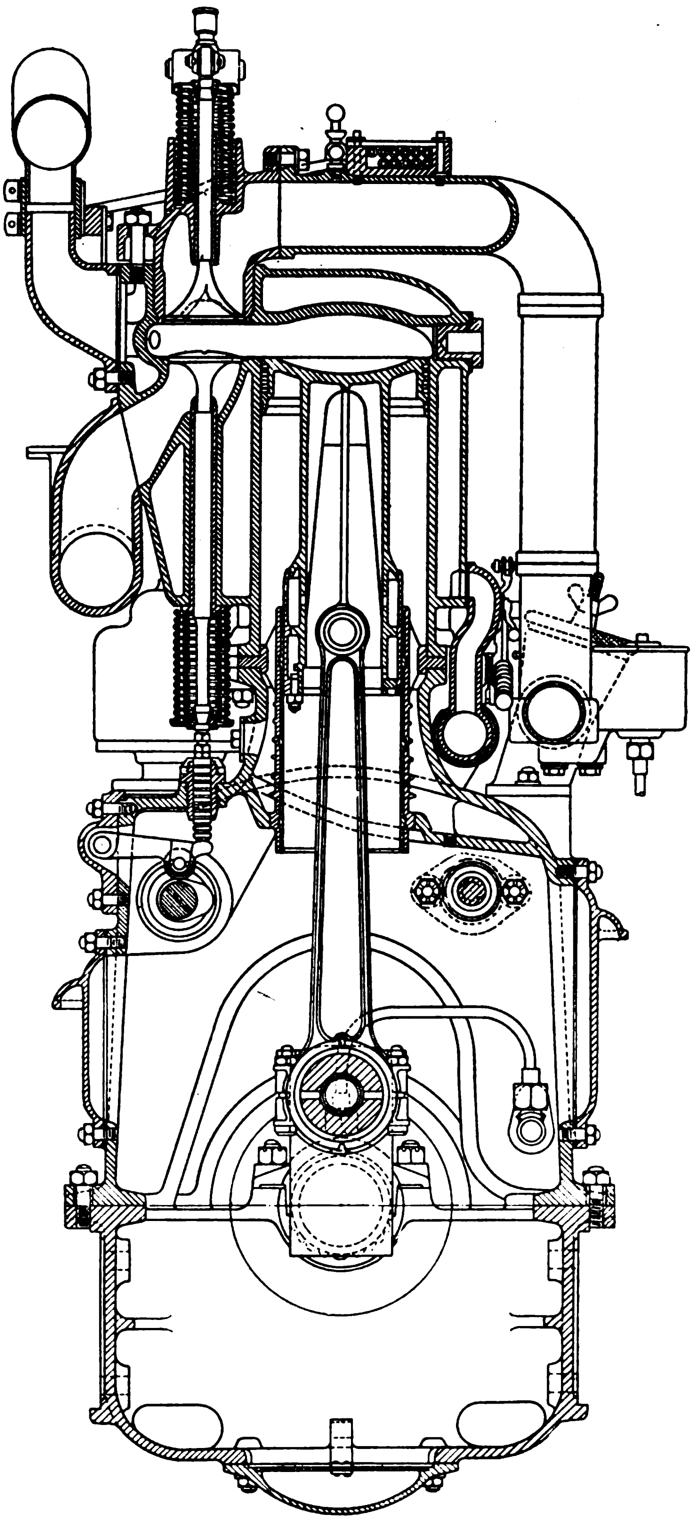
The crosshead taking the side thrust, the piston crown can be made with a relatively loose fit, as high as 0.060 in. clearance being allowed, and there is no pressure on the rings other than their own radial pressure, which is required for retaining compression.

Piston Design Insures Easy Cooling

A further object was to insure quick radiation of heat from the piston head, which is accomplished by a thick piston crown assisted by the smaller diameter downwardly extending piston tube. This obviates the necessity of relying on a piston skirt.

By securing the wrist pin in the lower or crosshead part it is far removed from the piston head, and its lubrication is proportionally simplified.

The wrist pin possesses several other advantages, due to this unusual location. The pin is short as compared with that used in the skirted piston, and the bosses carrying the ends of the pin are close up against the sides of the connecting rod. This reduces the bending moment on the rod and allows of using not only a shorter rod, but one of smaller diameter, and consequently reduces the reciprocating weight. It is possible to use a pin which floats in the top of the connecting rod and also in the crosshead bosses, which obviates any tendency to local



Cross section through the Ricardo engine, showing the unusual double-diameter piston with crosshead

wear on the pin, in that it tends to a slow rotary motion.

Among other advantages of this mounting of the wrist pin is that it is properly located with reference to the crosshead sleeve, which is the skirt of the piston. It is located approximately midway between the ends.

This crosshead design of piston prevents direct radiation of heat from the piston head to the crankcase, and so keeps the lubricating oil in the case cool. This is largely due to two factors: First, the heat from the piston head is largely radiated by the piston tube, and before it can reach the crankcase it has to be transmitted through the crosshead. Radiation from the piston tube is accelerated by having all the air entering the carbureter pass through the cylinder between the piston head and the crosshead. This air passes to the carbureter at as high a temperature as 150 deg. F. when the atmospheric temperature is 60 deg. F.

The crosshead piston has advantages from the standpoint of lubrication. The piston head carrying the rings requires very little oil, just enough to keep the rings working and to furnish a film on the wall. In most engines the rings get too much oil and a good deal of carbonization of oil occurs, to the detriment of the piston rings and the cylinder walls. In the Ricardo engine a small portion of the crankcase oil mist is carried into the cylinder space between the piston head and the crosshead by the air passing to the carbureter. This is sufficient for the piston crown. At the bottom of the cylinder the crosshead guide is exposed directly to the crankcase mist, and receives an adequate oil film for the close fit of the crosshead. Special lubrication economy is obtained, and the averages from the 3000 engines in use show an oil consumption of 0.012 pint per brake-horsepower-hour on new engines, which drops to 0.0075 pint per brake-horsepower-hour after use.

Still another advantageous feature of the Ricardo construction is that unburned fuel leaking down past the piston head does not enter the crankcase lubricant. Any heavier fuel particles that get by the piston head are picked up by the air passing to the carbureter and are again carried into the carburetion system. This factor is very desirable for using kerosene and also for gasoline in cold weather.

Not the least interesting aspect of this piston design is that it seems to furnish the missing link with aluminum alloy pistons, namely, the means of preventing piston slap when an engine is cold. The aluminum alloy piston has become universal in European aviation engines, where piston slap of a cold engine does not count. However, in passenger cars this slap must be eliminated, and it is also undesirable in the truck and the farm tractor. Ricardo designs the piston head with a loose fit, with as much as 0.060 in. clearance, but fits the crosshead as close as 0.004 in. The crosshead takes the side thrust and there is no slap.

The Ricardo engine was adopted for tank work owing to the impossibility of getting all the Daimler-Knight engines needed. The tanks originally used the 105-hp. six-cylinder Daimler-Knight, and Ricardo was asked to design his engine to give 113 hp. and to fit in the space used by the Daimler-Knight. The first design was a four-cylinder, 5⅝ by 7½ in., that gave 113 hp. at 1200 r.p.m. A six-cylinder design with the same cylinder sizes gave 170 hp. at 1200 r.p.m. To date four different sizes have been manufactured. The third model has six cylinders, 6¾ by 7½ in., and gives 255 hp. at 1200 r.p.m. Recently a twelve-cylinder job has been developed which would be interchangeable with the Liberty engine for certain uses.

Left—Sectional view of the Ricardo crosshead piston, showing method of attaching the cylindrical crosshead. Center—The piston in place in the engine. Right—Sectional view, showing how the carbureter air is drawn past the ribbed sides of the crosshead guide

Apart from the piston design, the engines are conventional types, with single cast-iron cylinders having valves in pockets on one side, the exhausts in the bottom of the pockets and the intakes in the tops, or directly above the exhausts. Both are operated from a single camshaft within the crankcase.

Using the crosshead piston increases the engine height approximately two-thirds of the stroke, which in the case of the 7½-in. stroke engine referred to adds 5 in. to the height. There is an increase of 10 to 15 per cent in engine weight as compared with the same sized engine using a skirt piston. A cold compression of 85 lb. gage is used. The mean effective pressure in the 5⅝ by 7½-in. size is 100 lb., and in the 6¾ by 7½-in. size is 106.5 lb.

Before going into tank use each engine is given a severe test and every fifteenth engine is given a 200-hour test in four runs of 50 hours each at full load on a dynamometer. No work can be done on the engines under test between the 50 hour periods. Every engine has to run 10 minutes while tilted at an angle of 30 degrees without load, and at the end of 10 minutes must go onto full load without smoking or missing. At the end of the 200-hour tests no carbon deposits have been found on the cylinder heads, the only indication of carbon being a mahogany color.

In the design of the engine the use of alloy steels was not permitted by the Government, in order to conserve these steels for the aviation program.

The engine has a mechanical efficiency of 386 per cent when starting up and 87.5 per cent after running.

The design of the engine parts to admit of the cross-head piston, which is a two-diameter one, does not call for unusual complications, as the cross-head guide fitting into the bottom end of the cylinder accomplishes this, leaving the cylinder casting identical with that in an engine using a skirted piston. The crosshead guide is an air-cooled aluminum alloy sleeve supported by a flange which is anchored between the cylinder base and the crankcase. The lower end of the sleeve fits into a sub-top of the crankcase. In the early designs this cross-head sleeve or guide was of bronze, lined with white metal, but aluminum alloy has been found to give very excellent results. The clearance of the crosshead in its guide ranges from 0.0035 to 0.006 in.

The piston, a die casting, has the crown slightly concaved, and only carries the very thin piston rings, which have a thicker radial measurement. Below the rings the very brief piston skirt is cut back, leaving a clearance of 0.020 in. In manufacture it has to be machined on the two cylindrical surfaces.

The crosshead sleeve is a cast-iron ring or shell fitting over the lower end of the piston tube and is secured thereto by four small bolts. It is an easy push fit on the piston tube. It is supported on the piston tube by three circular bands, the middle one being on the center of the wrist pin. The sleeve can be either cast iron or a steel forging, the former serving for commercial engines.

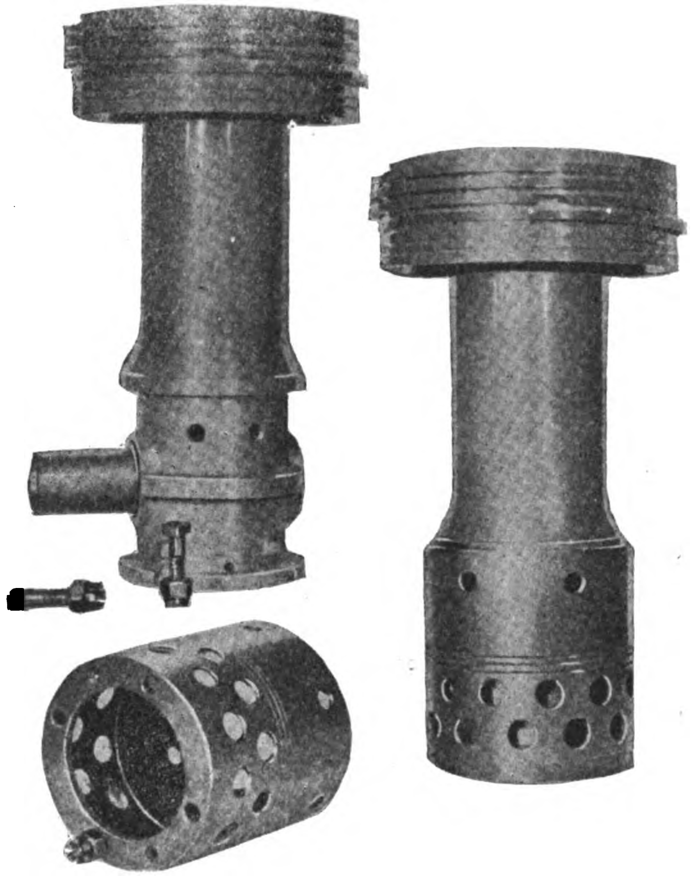
The crosshead piston permits of a short wrist pin, which is bushed in the end of the connecting rod and also in the crosshead bosses, allowing the pin to float. It is oiled by the crankcase mist, and the quantity supplied is quite independent of the throttle.

Nothing unusual is found in the valves and operating parts. They are of 3 per cent nickel steel, low carbon and case hardened. Phosphor bronze valve guides are used. There is little if any pitting of the heads. The timing is:

Inlet valve opens 20 deg. late.
Inlet valve closes 17 deg. late.
Exhaust valve opens 55 deg. early.
Exhaust valve closes 5 deg. late.

A careful masking of the inlet valves has shown very satisfactory results.

In carburetion use is made of the space between the crankcase top and the sub-top for the circulation of air around the crosshead guide. The air enters at one side and passes out to the carbureter on the other side. A portion of the air is drawn directly round the crosshead guide, and the remaining portion passes between the guide and the cylinder through slots provided for this purpose. On the upward stroke of the piston the air is drawn through these slots at a high velocity, and impinges



The Ricardo piston complete and disassembled, showing the crosshead which is bolted to the piston extension

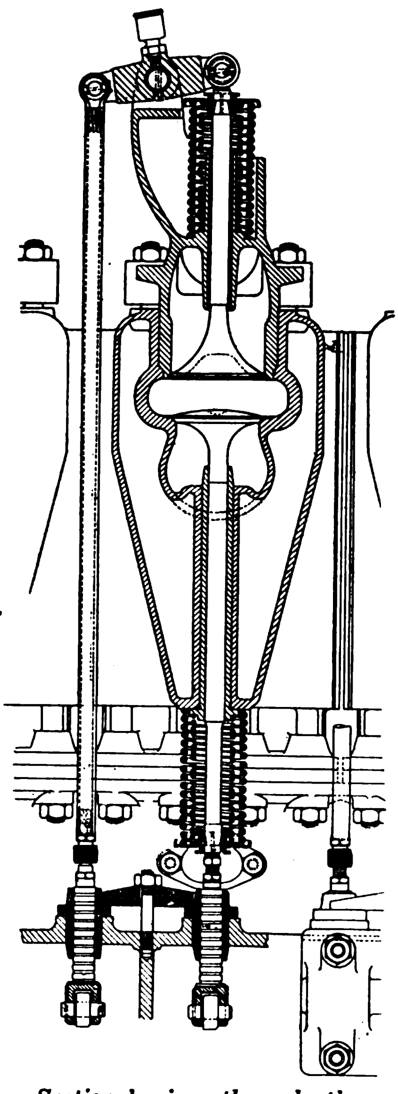
upon the crown and stem of the piston, thus effectually cooling them. On the downward stroke this heated air is discharged again into the chamber surrounding the guides, and thence into the carbureter. By this means the piston and crosshead guide are kept cool and the carbureter air is warmed.

It is found in practice that the heat abstracted from the piston and crosshead guide is just sufficient to overcome the latent heat of evaporation of the gasoline when running on full load, and rather more than sufficient on reduced loads. Tests carried out with thermometers fitted in the induction piping above and below the carbureter have shown that when running on full load with an atmospheric temperature of 60 deg. Fahr. the air, after passing round the crosshead guides and pistons, entered the carbureter at a temperature of 130 deg. Fahr.

The temperature immediately above the throttle was found to be 70 deg. Fahr., and near the top of the induction pipe, where evaporation appears to be complete, it was found to be 60 deg. Fahr., showing that the heat abstracted from the pistons and crosshead guides was just sufficient to replace that absorbed in overcoming the latent heat of the fuel, while the total drop in temperature of 70 deg. Fahr. showed that practically the whole of the fuel was evaporated before entering the cylinder. On a light load, with consequent reduced air circulation, the temperature of the air entering the carbureter rose to 150 deg. Fahr., and the temperature near the top of the induction pipe was sufficiently high to check condensation at reduced loads. The free circulation of air through the upper portion of the crankcase tends to keep the lower portion cool, so that no oil cooling is required. Further, the crankcase is not exposed to the heat radiated from or carried away by the lubricant from the inside of the piston crown.

As the upper end of the piston is to a certain extent isolated from the crankcase, special provisions had to be made to insure its lubrication. The lower portion of the stem of the piston is provided with a few small holes, and the crosshead sleeve which surrounds it is also provided with a ring of small holes so placed that these holes are uncovered above the guide at the top of each stroke. On the upward stroke of the piston air is drawn through slots provided in the flange of the crosshead guide between the guide and the cylinder, and passes at a very high velocity around the crosshead sleeve; in doing so it draws a small proportion of air and oil mist from the holes in the crosshead sleeve, which are in communication with the crank chamber through the corresponding holes drilled in the piston stem. The oil issuing from these holes in the form of a mist is picked up by the rush of air and sprayed over the cylinder walls while the piston is near the top of its stroke; the total quantity of oil drawn out in this manner is exceedingly minute, but it is sufficient for the maintenance of the piston rings. The whole operation is similar to that of a carbureter in which the slots in the crosshead guide correspond to the choke tube and the holes in the sleeve to the jets. The control of the quantity of oil delivered in this manner is governed by the area of the slots and the size or number of holes provided in the sleeve.

It will be noted that by this means the lubrication of the cylinder walls is continuous, that it is independent of the suction in the cylinder, that oil is only supplied to the cylinder walls in the quantity required by the piston rings, and that oil which has clung to the walls and become partially carbonized does not find its way back into the crankcase.



Sectional view through the valves and valve gear of the Ricardo engine

The advantages of the Ricardo piston may be summarized as follows:

(1) The lubrication is under complete control, and is independent of the suction in the cylinder; consequently the oil consumption, the tendency to carbonize both the piston and combustion chamber, and the risk of oiling up the sparking plugs are all reduced to the minimum.

(2) The piston friction is reduced to about half that which obtains with an ordinary trunk piston.

(3) Owing to the fact that the crosshead and guide are relatively cool, and that both are maintained at approximately the same temperature, a very fine running clearance can

(Continued on page 443)

Generation and Storage of Energy in Magnetos

How the Spark Energy Is Generated by the Armature Motion and Stored in the Magneto During the Short Circuit Period

By Harry F. Geist, E. E.

THE magneto generator, as used for ignition purposes, generates and stores the energy which subsequently goes into the ignition spark, during a period of operation while its winding is short-circuited. When the spark is desired, the winding is suddenly open-circuited, with the result that the stored energy is delivered in the form of an electrical spark.

Fundamentally, this stored energy, which is electromagnetic in form, is present in the combined electrical and magnetic circuits of the machine in the form of a reactive magnetic field and also in the form of a distortion of the excitation flux distribution due to this reactive flux, that is very different from what the flux distribution would be on open circuit for the same armature position, so that it naturally follows that a sudden change from the short circuit to the open circuit condition will result in a very sudden magnetic readjustment that produces the delivery of the stored energy to the ignition spark.

It is the purpose of this article to explain how the energy is generated due to armature motion and stored in the magneto on short circuit, pointing out by the aid of diagrams how the reactive flux is set up, influencing the shifting of the main or excitation flux from the magnets of the machine, and affecting current flow in the windings. The writer will endeavor to cover briefly all the important phenomena connected with the short-circuit operation of the ignition magneto.

In AUTOMOTIVE INDUSTRIES, Vol. XXXIX, page 616, in an article, "Magnetism In Magneto Generators," under Analytic Measurements, the writer gave a brief description of the physical dimensions of a low-tension magneto and of the set-up for the oscillographic test by which the oscillogram of the open circuit e.m.f., illustrated in Fig. 4 of that article, was taken. Special attention is here called to the fact that the oscillogram shows that when the armature was in the vertical position a relatively high voltage was generated.

Short Circuit Current

In Fig. 1 is now presented an oscillogram showing the current generation on short circuit for the same machine, taken under the same general testing conditions, so that in this oscillogram, just as in the oscillogram of the open-circuit e.m.f., the armature position is definitely marked.

Fig. 1, therefore, represents both a current-time and a current-armature position record of the performance of the machine on short circuit, at a speed of about 630 r.p.m., as checked directly from the 60 cycle wave represented therein.

The principal disclosures of this record are that the current wave is a very broad and flat one, indicating considerable firing range in the magneto, and that the current changes its polarity each time the armature passes the vertical position for this particular speed of operation. The current flow in amperes is also indicated on the oscillogram and the sequence of events is as shown by the arrow.

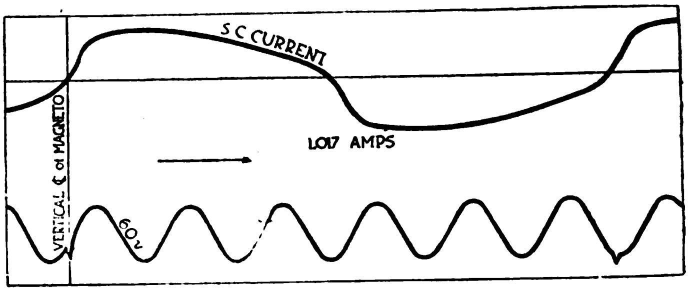


Fig. 1—Oscillogram of short circuited armature current

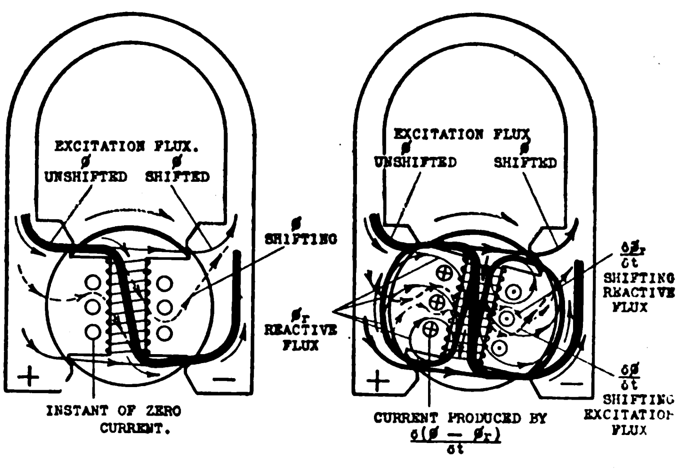
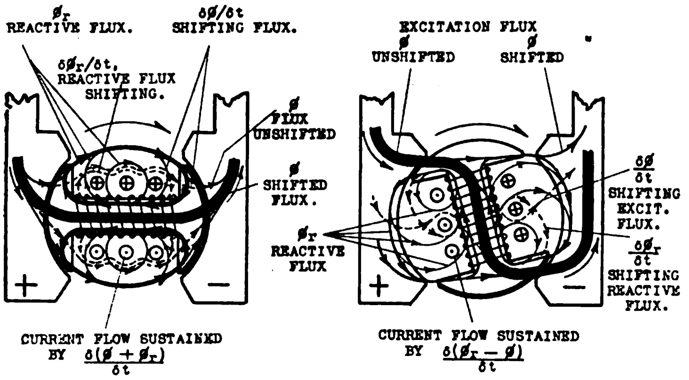
By comparing the short-circuit current wave with the open-circuit voltage wave, it will be seen that there is a lag between the armature position at which the short-circuit current rises to its maximum and that armature position at which the open-circuit e.m.f. rises to its maximum. It is this lag or retardation effect upon the manner in which the generating flux shift is produced on short circuit as compared with the more natural shift which takes place on open circuit, that is caused by the reactive flux set up in the magnetic circuits of the machine due to current flow in the generating winding.

The following flux distribution diagrams (Figs. 2, 3, 4 and 5) represent an attempt to show as completely as is possible how the reactive flux is set up in the machine, and its effect upon the excitation flux distribution, as well as the manner in which both the reactive and the excitation fluxes shift with respect to the winding.



Figs. 2 and 3—Showing flux distribution for two armature positions



Figs. 4 and 5—Flux distribution for two other armature positions

In these diagrams, just as in discussions of magnetic phenomena, the excitation and the reactive fluxes will be shown as separate entities, even though they do not actually exist as such, and the general plan is followed of joining these forces where they flow in the same direction through the same path, and of giving them slightly separated paths where they tend to flow in opposite directions in the same path. An endeavor has been made also to show the fluxes in about the proportions in which they exist for the different armature positions shown.

Shifting fluxes are shown in dotted lines and are given a curved effect with respect to the conductors they are shifting across. In connection with shifting fluxes, it might be pointed out here that as the armature face tips leave the pole piece tips, and as the opposite tips meet, excitation flux will shift across the winding, leaving the separating tips toward the meeting tips. For the direction of rotation shown in Figs. 2, 3, 4 and 5, this shifting excitation flux travels down on the left and up on the right-hand side of the coil, or always toward the "shifted flux" as designated.

As current increases in the winding, the reactive forces increase, the loops of reactive flux increase in number, and in so increasing, additional loops of reactive flux shift across the turns of the coil, beginning at the magnetic center, until they include the path formed by the armature core, armature faces and pole pieces. For decreasing current, these loops in dying out will decrease in the scope of their path inward toward the magnetic center of the winding and thus also will shift across the coil turns. This shifting of reactive flux has an effect similar to the shifting of the excitation flux, the effect being in proportion to its rate.

In these diagrams, a direction of rotation and a polarity of the magnets are assumed, and one face of the armature is shown heavier than the other in order that the amount of armature motion from one position to another be more easily followed.

Fig. 2 shows the armature in the vertical position, which, according to the oscillogram, Fig. 1, is the position of zero current. The conditions as represented in Fig. 2 depend upon phenomena occurring as the armature approaches the vertical position, so that Fig. 2 will not be discussed until after Fig. 5.

Position of Zero Current

As the armature passes from the vertical position to that represented in Fig. 3, the current rises toward its maximum value. This current is due to the fact that the excitation flux shifting across the coil generates an electro motive force that causes current flow in the closed circuit. While this current producing voltage is purely the result of the excitation flux shift and will vary as $\delta\phi/\delta t$ varies, it is further influenced by the fact that as the current increases in value, the reactive flux ϕ_r will increase in value correspondingly and will shift across the coil at a rate $\delta\phi_r/\delta t$. This shifting of reactive flux takes place in a general way in the opposite direction to that in which the excitation flux is shifted across the coil, so that it is evident that the current is produced by the resultant of these two shifts, which is expressed by $\delta(\phi - \phi_r)/\delta t$. Owing to the fact that the generating shift must be greater than the reactive shift which it produces, this resultant shift is expressed by the difference as shown. The current flow in the winding will be in the direction indicated by the three turns in cross section.

Attention is called in Fig. 3 to the fact that the loops of reactive flux flow in the same direction as the excitation flux at the separating armature and pole piece tips, and in an opposite direction at the meeting tips, which accounts for the fact that the excitation flux is retarded in its shifting by the reactive flux, for it will be appreciated that on open circuit, with an absence of the reactive flux, the direction of the excitation flux through the armature would be directly opposite. The diagram also shows that all the reactive loops do not interlink with all the coil turns and shows that the magnetic center, that is, the center from which all reactive loops arise and return, is at the opposite end on each side of the coil from the separating tips.

Fig. 3 shows the armature in about the position of maximum energy storage. This energy exists, as was previously mentioned, in the presence of the loops of reactive flux interlinked with the coil, and in the fact that the excitation flux is held in an unnatural path with respect to the coil by this reactive flux. The energy which is thus stored is generated by the shift of the excitation flux, produced by the motion of the armature and its consequent co-action with the pole pieces of the machine.

Position of Maximum Current Flow

As the armature passes on to a position of about 50 deg. beyond the vertical position, the current reaches its maximum value and then begins to decrease in amount, because the actual generation of energy has dropped off to a rate that is less than the amount that is being continually consumed in the copper and iron losses of the machine.

Fig. 4 shows the armature when it has about reached the horizontal position, and illustrates the phenomena taking place with the current thus decreasing in value. This figure shows practically all of the excitation flux shifted and passing directly through the armature core, but shows a stray flux still unshifted that is negligible for this position. The reactive flux loops ϕ_r will take the path as shown, and it will be noticed that these loops have a more difficult path than that of Fig. 3.

With the current decreasing, and the reactive flux decreasing likewise, there will be a shifting of the reactive flux $\delta\phi_r/\delta t$ across the coil as these loops die out toward the magnetic center of the winding. This center, it will be seen, has changed for each side of the coil to a position on the vertical center line of the machine, about as shown.

The dying out of the reactive flux and the shifting of the rest of the excitation flux are both now in the same direction with respect to the coil, so that from the instant the current begins to decrease, up to the neighborhood of the position of Fig. 4, the resultant flux shift is seen to be $\delta(\phi + \phi_r)/\delta t$. This resultant flux shift rate has a sustaining effect upon the current flow and accounts for the fact that the current decrease is very gradual. When all the excitation flux is completely shifted with

respect to the coil this resultant flux shift rate becomes $\delta\phi_r/\delta t$.

As the armature passes on toward the position of Fig. 5, the tendency is for the excitation flux to again begin to shift with respect to the coil, passing down on the left-hand side and up on the right-hand side, thus changing from the path of the unshifted to the path of the shifted excitation flux, as shown in the diagram. The reactive flux is still present and still decreasing in value, so that it is seen that the shifting of the excitation flux now opposes the shifting of the reactive flux, *i.e.* the motion of the armature is now tending to generate energy to destroy the stored energy still existing in the machine, with the result that the resultant flux shifting rate is now $\delta(\phi_r - \phi)/\delta t$. Here still the component $\delta\phi_r/\delta t$ is the greater, but $\delta\phi/\delta t$ is overcoming it at an increasing rate. In Fig. 5 it will also be noticed that the magnetic center for each side of the winding is directly opposite from where it was in Fig. 3, showing how the magnetic center of the machine changes with the armature during its rotation.

Shifting of Flux Balances Stored Energy

When the armature reaches the vertical position, as represented in Fig. 2, the shifting of the excitation flux has completely overcome the stored energy and the current has reached the zero value. This position is an instantaneous one, and the shifting flux ϕ shown is part way between the unshifted and shifted positions. Due to the fact that the current is zero, there can be no reactive flux left from the original generation of Fig. 3 or resulting from the new generating tendency of the shift explained for Fig. 5.

For the next half revolution the magnetic and electrical phenomena repeat themselves, but inasmuch as the armature and coil are inverted with respect to the field, from what they were during the half revolution discussed, the forces set in action will be of opposite polarity.

A general review of the diagrams shows that useful generation takes place from the vertical position of the armature for about 50 deg. of motion, after which the coil serves almost purely as a reservoir, this reservoir being emptied by the generating effect during the last part of the half revolution, in addition, of course, to the continual consumption of energy by the coil resistance and the iron of the machine.

During the half revolution, the resultant flux shift is seen to change from $\delta(\phi - \phi_r)/\delta t$, to $\delta(\phi + \phi_r)/\delta t$, and after the original flux shift $\delta\phi/\delta t$ has died out and the new one begins, to $\delta(\phi_r - \phi)/\delta t$, so that it is apparent that the reactive flux plays an important part through the complete half revolution.

Throughout the phenomena, the general effect of the reactive flux is to stabilize the current flow in the machine, hindering it in its generation, and retarding also its decrease. This retardation effect results, as has been shown, from both a regenerative effect upon the coil itself and from the distorting effect upon the distribution of excitation flux.

Regenerative Effect of Reactive Flux

The regenerative effect of this reactive flux upon the coil itself is what is known as the effect of inductance, while the distorting effect upon the distribution of the excitation flux is what is known as armature reaction. A third limitation to current flow, which is well known, is the resistance of the winding itself, but inasmuch as its general effect has little bearing on the wave shape of the current flow on short circuit, only a mention of it will be made at this time.

It is well known that an electromagnetic circuit, having an inductance L, in which a current i is flowing, will store energy in accordance with the following equation:

$$W_1 = \frac{L\,i^2}{2} \qquad (1)$$

In addition it is also apparent that during the armature motion from the position of Fig. 2 to that of Fig. 3 or until $\delta\phi_r/\delta t$ begins to exceed $\delta\phi/\delta t$, each line of reactive flux will hold an equal line of excitation flux in an unnatural position with respect to the coil, so that for this range of armature positions the stored energy due to armature reaction must be about equal to that stored due to inductance, or the total stored energy can be expressed by,

$$W = Li^2 \qquad (2)$$

Therefore the inductance effect and the armature reaction are both factors in the stored energy of the magneto.

The value of the current i in amperes is obtainable for any armature position directly from the oscillogram of Fig. 1, so that if the inductance in henrys of the circuit can be ascertained for different armature positions, the stored energy for any armature position is calculable in joules from the foregoing equations.

If an alternating electromotive force, of known frequency and sinusoidal in its wave shape, is impressed across the terminals of the magneto coil, with the magnets removed from the machine, and this emf. is of such a value that as small a current as can be accurately measured will flow, then for any armature position the impedance Z of the circuit is obtainable, by dividing the impressed voltage by the current flow resulting.

Impedance

It is well known that the impedance Z is equal to the square root of the sum of the squares of the reactance X and the resistance R of the coil, and since R can be easily obtained by the use of a Wheatstone Bridge, and in this case proved to be 4.02 ohms, the value X is readily obtainable from Z and R by calculation.

For a sinusoidal voltage wave form of frequency f the following law holds true,

$$L = \frac{X}{2\pi f} \qquad (3)$$

and from it the value of the inductance can be calculated for any armature position for which X is known.

A series of inductance measurements was made following the above method for different armature positions of the magneto from which the oscillogram of Fig. 1 was taken, and the results are shown in the Inductance-

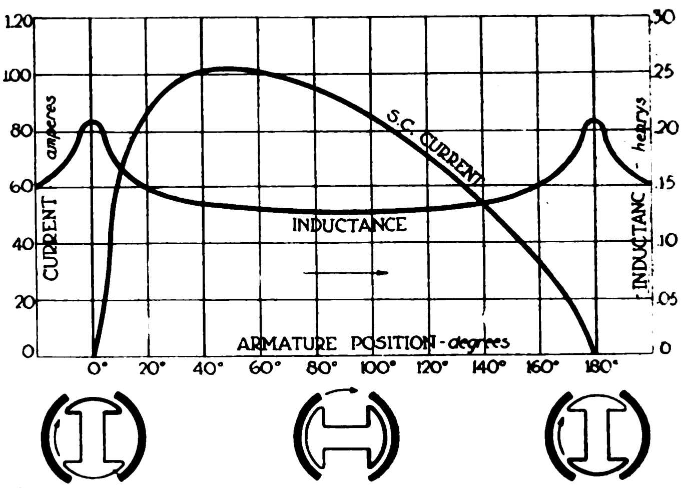


Fig. 6—Armature position-inductance curve

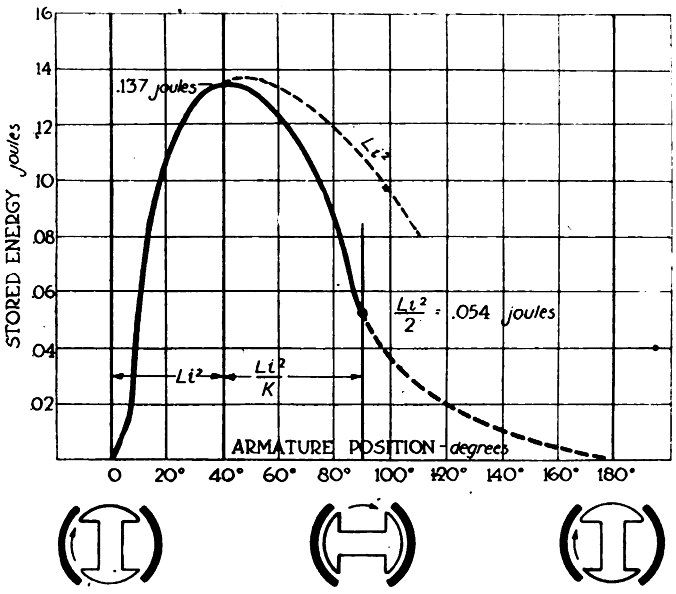

Fig. 7—Curve of stored energy

Armature Position curve of Fig. 6. The short-circuit current as reproduced from the oscillogram is also included in Fig. 6, so that from these two curves it is possible to calculate the amount of stored energy in the magneto for different armature positions.

In Fig. 6 attention is called to the fact that the inductance of the circuit is a maximum when the armature is in the vertical position. This is what would naturally be expected because for this position the reactive flux has complete iron paths through the armature core, armature faces and pole pieces, with the exception of the clearance gap between the rotor and the stator, while for the horizontal position the loops of reactive flux have a much more difficult path and the inductance will, therefore, be a minimum for that position. Thus it is seen that the inductance of the circuit varies very materially as the armature changes positions during its rotation. The resistance of the winding will, of course, be constant.

It was pointed out that the stored energy for armature positions from Fig. 2 to Fig. 3 is the sum of the effects of inductance and armature reaction, and is therefore the amount calculable from equation (2) by the use of the data represented in Fig. 6. Equation (2) holds true in this magneto for the speed at which the oscillogram was taken, from the vertical position to about 40 deg. after the vertical.

Value of Stored Energy

In Fig. 7 the calculated results are plotted and the curve shows how the stored energy increases from zero to its maximum of about 0.137 joule as the armature moves through the first 40 deg. From the 40 deg. position on to the 90 deg. or the horizontal position, the armature reaction component of the stored energy gradually dies out, so that for the horizontal position the stored energy will be due almost entirely to inductance and will be of an amount calculable from equation (1), which gives 0.054 joule.

Between the 40 deg. and 90 deg. positions, therefore, the stored energy will follow the equation,

$$W = \frac{L\,i^2}{k} \qquad (4)$$

where k is a numerical quantity varying from 1 to 2 for the included armature positions, so that the curve for the range of positions from 40 deg. to 90 deg. will have to be to some extent an approximation.

The amount of stored energy after the horizontal position for the last quarter of a revolution is of very little consequence, because the stored energy is below a useful value even before the armature reaches the horizontal position.

From Fig. 7 it is seen that the magneto under consideration has a comparatively high value of stored energy at 630 r.p.m. for about 50 deg. of motion. This range, of course, results from a constant speed of operation. In starting an engine, with the spark occurring late, say at 60 deg., the starting speed will be comparatively low, perhaps only about 200 r.p.m., so that the energy available for the spark at that position of the armature and speed will not be as high as that shown in Fig. 7. The true firing range of a magneto has to allow for low-starting speeds. However, it is evident that this magneto has ample firing range for ordinary service. It is also apparent by comparing the Stored Energy-Armature Position curve of Fig. 7 with the Current-Armature Position curve of Fig. 6, that there is a great deal of difference between the current range and the sparking range of a magneto.

Stored Energy on Short Circuit Dissipated in Heat

The question might be asked as to what becomes of the energy generated and stored in the machine on continuous short circuit, when the circuit is not interrupted to produce an ignition spark. All the energy that is generated in the machine during each half revolution of the armature is dissipated during that half revolution in the form of iron losses in the magnetic circuits and copper losses due to the resistance of the winding. At those positions of the armature where energy generation is very high, the energy generation exceeds the amount consumed, so that most of the energy is stored as previously explained, but after the generation dies out the stored energy will continue to be expended in the copper and iron losses.

During the period of generation, energy storage, and energy dissipation in copper and iron all take place simultaneously, so that a complete dispensation of the energy generated is practically impossible.

However, from the data contained in the oscillogram Fig. 1 in connection with the fact that the coil resistance R is known, it is a simple matter to determine the amount of copper loss, by the use of the following equation,

$$W_r = \int_0^t i^2 R\, \delta t \qquad (5)$$

where i varies with t as is recorded by the oscillogram, and R is 4.02 ohms. The indicated integration can be carried out by a step by step summation for small intervals of time δt covering the 0.0476 second required for the half revolution at 630 r.p.m.

Such a calculation made for this magneto shows the total copper loss for the half revolution to be 0.111 joule. Of this amount 0.08 joule was spent after the 40 deg. position from the 0.137 joule stored, so that it is evident from the difference that iron loss is also a very important consideration in this type of machine.

Energy Available for Spark

However, these calculations are secondary considerations in the phenomena that occur during the rotation of the armature, as compared with the simple, direct and fairly accurate determination that can be made of the energy available for an ignition spark for any armature position on the firing range of the magneto.

The discussion thus far has dealt principally with the phenomena occurring during one complete magnetic shift of the machine for one particular speed of operation. In

order to show how the performance of the magneto varies with the speed at which the armature revolves, the effective short-circuit current was measured by means of an electro-dynamometer for different speeds ranging from zero up to about 1400 r.p.m.

The results of this test are plotted in the form of a graph in Fig. 8, which shows how the current increases very rapidly for increases of speed until the armature attains a speed of about 300 r.p.m., after which the increase is more gradual and after 600 r.p.m. the current becomes practically constant.

As the speed increases from zero, the tendency is for the impedance voltage generated in the machine to increase with it and thus cause a higher current flow, but as the speed increases, the resulting current changes and their consequent inductive effects will set up a counter e.m.f. that also increases with the speed, so that a speed will soon be reached at which the increase in generated voltage is neutralized completely by the counter e.m.f., with the result that the current flow will then maintain a constant effective value regardless of speed increases.

From an energy standpoint, an increase in armature speed means additional mechanical energy to be transformed into electrical energy, so that there must be an increase in the electrical energy generated. Part of this increased energy is consumed in iron losses, which increase rapidly with the speed, while the rest goes into increased energy storage, giving the machine a greater storage range and being accompanied by a broadening of the current wave shape.

Increasing or decreasing the number of turns of the coil will increase or decrease the inductance of the circuit, so that such a change in the winding will result in a change in the Speed-Current characteristic of the magneto performance. As an illustration of this change, the two dotted curves are included in Fig. 8. Any other changes in the physical proportions of the magnetic circuits of the machine that will increase or decrease the inductance of the circuit, without reducing the generative ability of the magneto, are also very good methods of adjusting the Speed-Current performance, although their effects upon the wave shape of the current generated and upon the firing range of the machine will have to be taken into consideration.

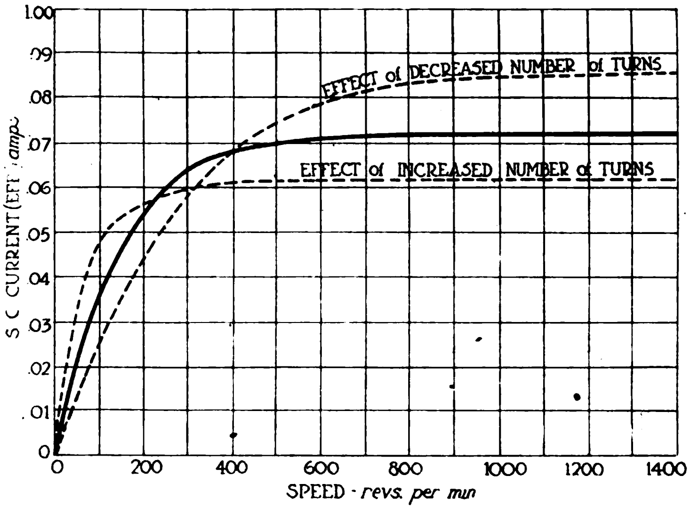

Fig. 8—Diagram showing effect of changing numbers of armature turns

While the foregoing treatise covering the generation and storage of energy in magnetos during its operation on short circuit is based upon tests and observations made upon a low-tension magneto, it must be understood that the same general laws and phenomena hold true for the generating winding of a high-tension magneto, inasmuch as the features that tend toward high generating and storage ability in a low-tension machine are also the basis of an efficient high-tension magneto.

Hoosier Clutch Redesigned

THE Hoosier single-plate dry-disc clutch, manufactured by the Hoosier Auto Parts Co., Muncie, Ind., has been redesigned and improved. This clutch is of simple construction and is provided with adjusting means whereby the points of support of the clutch clamping levers are moved in the direction of clutch action. The adjustment is made by loosening the adjusting screw, which enters the adjusting ring through a 5-in. slot in the cover plate, and turning it to the right end of the slot, whereby an adjustment of 1/64 in. is obtained. If a larger adjustment is required, the screw is taken out and inserted in a tapped hole then showing in the left end of the slot. The adjusting operation may then be repeated until the desired adjustment is obtained.

Details of Adjusting Ring

The adjusting ring is threaded, there being 10 threads to the inch, and screws over a threaded flange on the cover plate; as the ring moves out horizontally from the cover plate it moves the three clamping levers toward the clutch plates and maintains them in the same relative adjustment at all times, so that the pressure against the friction discs will always be the same all around.

The adjusting ring can be moved axially at least ¼ in., and as the two friction discs have a thickness of only ¼ in. each, the adjustment is sufficient to allow for any possible wear. Hoosier clutches are made in 10-in. and 12-in. sizes to fit all standard makes of engine and transmission and are adapted for either unit power plant or for separate transmission installations. They are also interchangeable with other clutches of similar type.

A New Windshield for Closed Bodies

Upper and Lower Parts in Inclined Planes Cutting Each Other in the Line of Vision—Greater Protection Against Rain Combined with Clear Vision Effect

By George J. Mercer

THE regulation slanting shield, set at an angle of 17 to 21 deg. from the vertical, possesses such merit that it is used on the majority of cars, but it has been found in practice that rain, when driven by the wind, will lay on the glass, even when the speed of the car is only 12 miles per hour. So the lower glass is made stationary and the joints at the side and bottom are made watertight, but assuming that the rain is coming toward the front on line *A* (Fig. 1), if the wind pressure is sufficient, the rain will be forced in the direction of the arrow and will enter the opening indicated by the line of vision. To prevent this, a rubber channel is slipped over the top edge of the lower glass, and the upper, when jammed tight against it, will form a step or offset from the glass surface and thus deflect the water, but this means that the front is closed entirely and the car is being driven through a misty glass. Of course, there are methods of minimizing this difficulty, such as wiping the glass with newspaper that contains a small quantity of kerosene, or having a wiper operated from the inside that will keep clear a space in front of the driver. Sometimes a double upper glass is used, the outer acting as a shield for the inner, but this latter will not keep condensation away. In fact, nothing is equal to a clear vision, and it does not have to be large to be effective.

At the Salon last January, Brewster & Co. exhibited an inside drive body on which the windshield, instead of being in one plane from top to bottom, was made up of two angles meeting in a point or apex at the opening, the same as the shield herein illustrated, the apex in the illustration being on the line of vision. Also, the member marked post C is continued down to the cowl to make a strong support for the roof and to withstand the impact against this member when the car is suddenly stopped and the pitch of the weight above is concentrated against the front. The Brewster body did not have to withstand such strain, as body and roof were exceptionally light; therefore, its front was formed only by the two angles. Also, the upper glass was not hinged at the top, but travelled up and down in grooves in the post and was operated by an inside handle, similar to a window regulator.

The chief advantage of this shield, however, is that the rain is deflected downward and away from the opening. Assuming that the rain is coming along line *B*, which is parallel to *A*, the line of travel when it meets the lower glass will be as indicated by arrow *B*, and if no rain can enter from below, it will be possible to open the upper glass just enough so that the rain will not enter, and a clear vision for driving is gained. Besides, no water can get into the car, except the negligible amount that may come in through the sides.

The construction of this front will present no difficulty to the body builder, though it involves a little additional work, as compared with the regular shield. The best plan will be to make this a one-piece casting of bronze, the casting to include the bottom member as well as the upright covering the lock pillar on the left side and the entire pillar on the right side. This necessitates welding in two places on the latter, at the top rail and the belt rail to the side panel. The cross member that will join the two side members together at the bottom is also a casting, in which a cored groove is cast to receive the lower glass. This cross front member is fastened

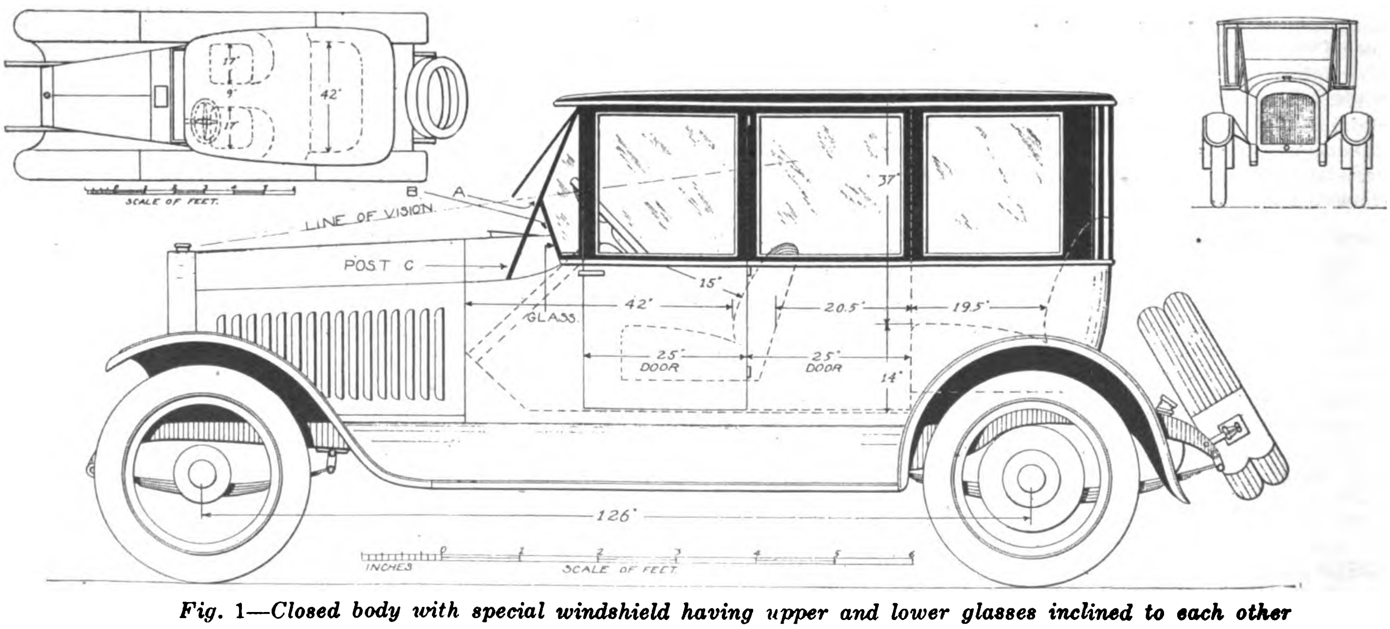

Fig. 1—Closed body with special windshield having upper and lower glasses inclined to each other

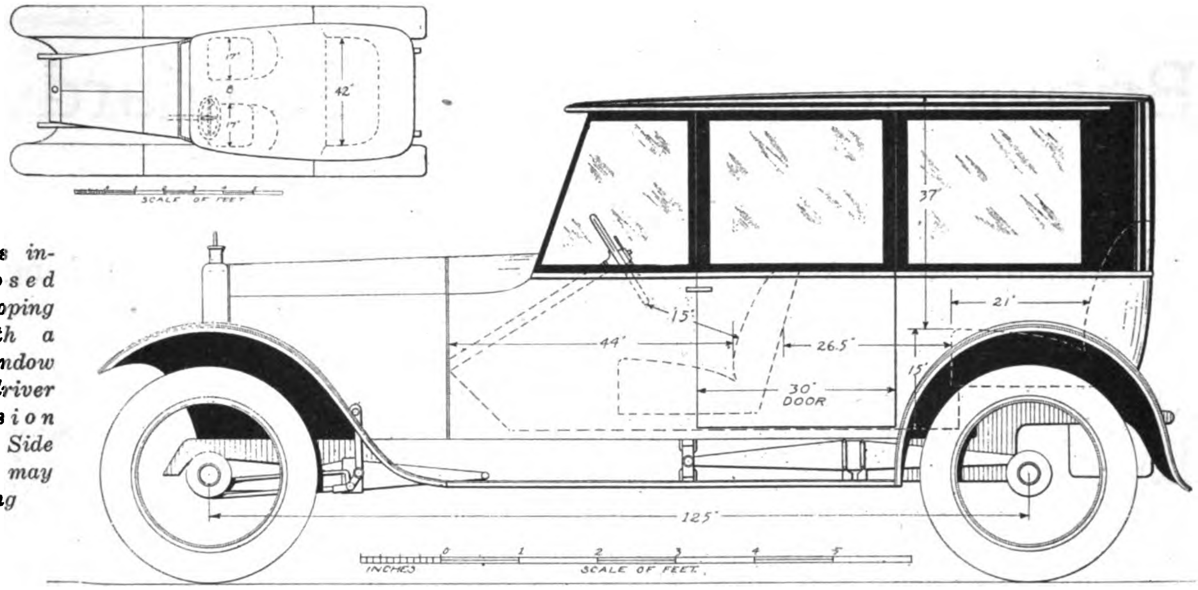

Fig. 2—In this instance the closed body has a sloping windshield with a large side window giving the driver unimpeded vision from the side. Side window may or may not be sliding

on top of the body cowl framing, and the joint is covered by the wide belt moulding, a continuation of the side belt that also covers the lap of the metal panel. This front appearance is illustrated in Fig. 1. One of the advantages of this shield is that it permits of a longer cowl line than ordinary.

With inside drive bodies the matter of vision is so complex that no single design can meet all the requirements. In connection with Fig. 1 the problem of keeping out the rain has been dealt with in such a manner that the glass may be opened when it is raining and still keep out moisture. Fig. 2 illustrates another phase of the problem of inside drive bodies. This represents a type of shield now in actual use.

The advantage of the shield shown in Fig. 2 is that the driver has an unimpeded vision from the side, which is not the case when a vertical post is placed near the front. When driving straight ahead this post is not objectionable, but when turning it is right in the line of vision. The merit of this large front glass is well understood and the reason that it is not more in use is because the slant line of the front renders it troublesome to lower and raise; besides, it must either be all the way up or all the way down, having no intermediate position. Some few make it stationary, but this is not necessary, as it can be lowered by having the front member that forms the angle glass frame extend below the hook channel about 3 in. This will always be engaged in the runway and will be sufficient guide for the up and down movement of the glass. When down the top of this front side member will wedge slightly between the bar and the lining board and keep it from rattling. This is the cheapest and most satisfactory and it works well in practice. The design, however, entails the use of central doors. By making the right front seat so it can be easily rocked forward, crowding of the rear compartment can be obviated.

Fig. 3 shows another model which can be as low, compact and light as the size of the persons using it will permit. For small people the height can be shaded down 3 in. and the length reduced considerably more than this. However, in reducing the length, care should be used that the window spaces remain of nearly equal size as this makes a better proportioned job. The single permanent line that cannot be altered is the rear line of the door. This must be kept as far back as illustrated, because the door when open is forward of the rear cut by a distance nearly equal to its own thickness, and sufficient clear space must be provided to pass the door and get back of the front seat top.

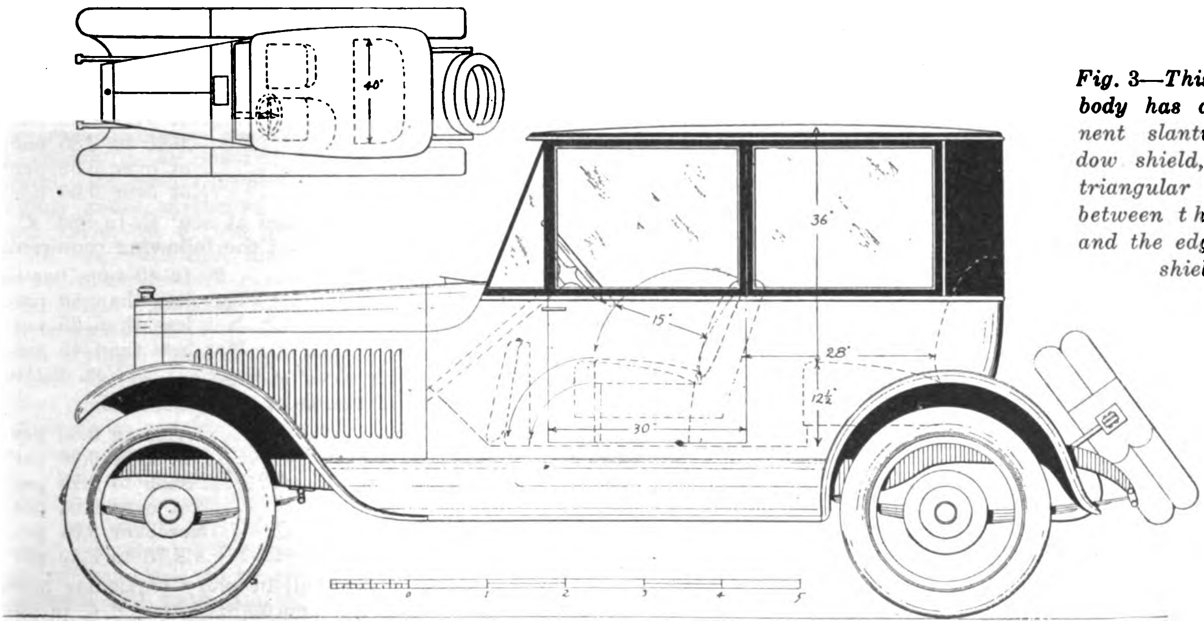

Fig. 3—This inclosed body has a permanent slanting window shield, with a triangular window between the door and the edge of the shield

British Adopt Twenty Standard Steel Specifications

Cover the Whole Range of Steels Used in Automotive Engineering—Both Chemical and Physical Properties Specified—Definitions of Terms Used

LONDON, Jan. 15—Twenty steel specifications specially written for automobile users and known as the British standard automobile steels have been adopted, and production has already started upon them. The twenty cover the complete gamut of automobile steels and represent the consensus of opinion of the steel makers, as well as the automobile makers, on what is needed for the automobile industry.

Research work was pushed ahead at a maximum pace by the steel makers, and within 11 months of the start of the research the steel makers were in production on most of the twenty grades.

The Institution of Automobile Engineers, which represented the automobile industry in this work, thinks it has a superior class of specifications to those adopted by the Society of Automotive Engineers, and looks to the S. A. E. to revise its list in accordance with the British ones.

The specifications for the British automobile steels have been agreed upon and declared standards by the British Engineering Standards Committee, which means that they are the official British standards and cannot be altered without the action of the B. E. S. C.

The specifications and tests of the British steels are:

E. S. C. 10 CARBON CASE HARDENING STEEL

Carbon	0.08 to 0.14 per cent
Silicon	Not over 0.20 per cent
Manganese	Not over 0.60 per cent
Sulphur	Not over 0.04 per cent
Phosphorus	Not over 0.04 per cent

This steel, when normalized at 900° C. to 920° C., shall pass in every particular the following check tests:

Tensile breaking strength	23 to 28 tons per sq. in.
Yield ratio	Not less than 50 per cent
Elongation	Not less than 30 per cent
Reduction of area	Not less than 50 per cent

It shall show a Brinell hardness test between Nos. 92 to 112.

E. S. C. 15 CARBON FOR CASE HARDENING STEEL

Carbon	0.12 to 0.20 per cent
Silicon	Not over 0.20 per cent
Manganese	0.65 to 1 per cent
Sulphur	Not over 0.07 per cent
Phosphorus	Not over 0.07 per cent

In check test, when normalized at 890° C. to 920° C., it shall pass in every particular the following test:

Tensile breaking strength	25 to 33 tons per sq. in.
Yield ratio	Not less than 50 per cent
Elongation	Not less than 28 per cent
Reduction of area	Not less than 50 per cent
Brinell hardness test	Nos. 103 to 143

E. S. C. 2 PER CENT NICKEL CASE HARDENING STEEL

Carbon	0.10 to 0.15 per cent
Silicon	Not over 0.30 per cent
Manganese	0.25 to 0.50 per cent
Sulphur	Not over 0.05 per cent
Phosphorus	Not over 0.05 per cent
Nickel	2 to 2.50 per cent

In check test, when normalized at 850° C. to 900° C., it shall pass in every particular the following test:

Tensile breaking strength	25 to 35 tons per sq. in.
Yield ratio	Not less than 55 per cent
Elongation	Not less than 30 per cent
Reduction of area	Not less than 55 per cent
Brinell hardness	Between Nos. 103 and 153

E. S. C. 5 PER CENT NICKEL CASE HARDENING STEEL

Carbon	Not over 0.15 per cent
Silicon	Not over 0.20 per cent
Manganese	Not over 0.40 per cent
Sulphur	Not over 0.05 per cent
Phosphorus	Not over 0.05 per cent

In check test, when normalized at 820° C. to 860° C., it must pass in every particular the following test:

Tensile breaking strength	25 to 40 tons per sq. in.
Yield ratio	Not less than 60 per cent
Elongation	Not less than 30 per cent
Reduction of area	Not less than 55 per cent
Brinell hardness test	Nos. 103 to 179

E. S. C 20 CARBON STEEL

Carbon	0.15 to 0.25 per cent
Silicon	Not over 0.25 per cent
Manganese	0.40 to 0.85 per cent
Sulphur	Not over 0.06 per cent
Phosphorus	Not over 0.06 per cent

In check test, after normalizing at 890° C. to 920° C., this steel shall in all particulars meet the following test:

Tensile breaking strength	26 to 34 tons per sq. in.
Yield ratio	Not less than 50 per cent
Elongation	Not less than 28 per cent
Reduction of area	Not less than 50 per cent
Brinell hardness	Nos. 105 to 149

E. S. C. 35 CARBON STEEL

Carbon	0.30 to 0.40 per cent
Silicon	Not over 0.30 per cent
Manganese	0.50 to 0.85 per cent
Sulphur	Not over 0.06 per cent
Phosphorus	Not over 0.06 per cent

In check test, when normalized at 850° C. to 880° C., this steel shall in all particulars meet the following requirements:

Tensile breaking strength	30 to 40 tons per sq. in.
Yield ratio	Not less than 50 per cent
Elongation	Not less than 25 per cent
Reduction of area	Not less than 45 per cent
Brinell hardness	Nos. 121 to 179

E. S. C. 3 PER CENT NICKEL STEEL

Carbon	0.25 to 0.35 per cent
Silicon	Not over 0.30 per cent
Manganese	0.35 to 0.75 per cent
Sulphur	Not over 0.04 per cent
Phosphorus	Not over 0.04 per cent
Nickel	2.75 to 3.50 per cent

In check test this steel shall in every particular meet the following requirements when normalized at 840° C. to 880° C.:

Tensile breaking strength	35 to 45 tons per sq. in.
Yield ratio	Not less than 55 per cent
Elongation	Not less than 24 per cent
Reduction of area	Not less than 45 per cent
Brinell hardness	Nos. 140 to 202

E. S. C. 1½ PER CENT NICKEL-CHROMIUM STEEL

Carbon	0.25 to 0.35 per cent
Silicon	Not over 0.30 per cent
Manganese	0.35 to 0.60 per cent
Sulphur	Not over 0.04 per cent
Phosphorus	Not over 0.04 per cent
Nickel	1.25 to 1.75 per cent
Chromium	0.75 to 1.25 per cent

In check test this steel, oil hardened at 850° C. and tempered at 600° C., shall meet the following requirements in every particular:

Tensile breaking strength	Not less than 45 tons per sq. in.
Yield ratio	Not less than 70 per cent
Elongation	Not less than 15 per cent
Reduction of area	Not less than 50 per cent
Brinell hardness	Approximately 179

E. S. C. 3 PER CENT NICKEL-CHROME STEEL

Carbon	0.20 to 0.30 per cent
Silicon	Not over 0.30 per cent
Manganese	0.35 to 0.60 per cent
Sulphur	Not over 0.04 per cent
Phosphorus	Not over 0.04 per cent
Nickel	2.75 to 3.50 per cent
Chromium	0.45 to 0.75 per cent

In check test this steel, when oil hardened at 820° C. and tempered at 600° C., shall meet the following requirements in every particular:

Tensile breaking strength	45 tons per sq. in.
Yield ratio	Not less than 75 per cent
Elongation	Not less than 15 per cent
Reduction of area	Not less than 20 per cent
Brinell hardness	Approximately 179

AIR-HARDENING NICKEL-CHROME STEEL

Carbon	0.28 to 0.36 per cent
Silicon	Not over 0.30 per cent
Manganese	0.35 to 0.60 per cent
Sulphur	Not over 0.04 per cent
Phosphorous	Not over 0.04 per cent
Nickel	3.50 to 4.50 per cent
Chromium	1.25 to 1.75 per cent

In check test this steel, air hardened at 820° C., shall meet the following requirements in every particular:

Tensile breaking strength	Not less than 100 tons per sq. in.
Yield ratio	Not less than 75 per cent
Elongation	Not less than 5 per cent
Reduction of area	Not less than 13 per cent
Brinell hardness	Approximately 418

A series of definitions with regard to different processes in steel manufacture as follows were also agreed upon:

Normalizing—Means heating a steel to a temperature exceeding its upper critical range and allowing it to cool freely in the air.

Annealing—Means reheating, followed by slow cooling. (a) It is to remove internal stresses and to induce softness. (b) It is to refine crystalline structure.

Hardening—Means heating a steel to its normalizing temperature and cooling more or less rapidly in water, oil or air.

Tempering—Means heating a steel to a temperature not exceeding its carbon change point so as to reduce hardness or increase toughness.

Cementing—Means heating a steel above its normalizing temperature in a medium which will increase the carbon content.

Core—The core of a case hardened bar is the interior portion which is substantially unaffected in composition by the cementing process.

Refining—Means reheating a steel to its normalizing temperature and is usually followed by quenching.

Tensile Breaking Strength—Means the greatest load sustained by a test piece expressed in tons per square inch of the original area of the test piece.

Yield Ratio—Means the ratio between yield stress and tensile breaking strength.

Reduction of Area—Reduction of area in per cent is the difference between the original and fractured areas expressed in percentage of the original area.

Cellon Insulating Varnishes

RECENT inquiries instigated by the German Ministry of Raw Materials have shown that both satisfactory and unsatisfactory results have been obtained in the use of cellon varnishes for insulating parts of electrical conductors and machines. This led the editor of the *Elektrotechnische Zeitschrift* to request Dr. A. Eichengrün of the Cellon Laboratory, Charlottenburg, to prepare a report on the experience he has gained, embodying his views on the causes of the troubles that have been met.

In the report it is pointed out that cellon varnishes should not be regarded as a "substitute" for oil varnishes, but that they constitute an entirely new and valuable insulating material with special properties. Cellon varnishes should be used only under particular conditions, and the choice of the correct variety is of the greatest importance. In contrast with oil varnishes that are absorbed and held by carriers such as cotton or silk coverings and require oxidizing by baking, cellon varnishes form solid coatings on bare metal by the evaporation of the liquid forming the cellon solution, no oven drying or oxidation in the air being required. Cellon varnishes are particularly suitable for insulating bare conductors, such as overhead conductors and bus-bars; sealing up cable ends; covering parts of machines, such as armature leads; forming protective coverings on wood or metal parts, such as handles, levers, hand wheels, etc.

Cellon varnishes are classified under 7 headings: (*a*) thin flowing and quick drying, to be painted on with a brush; (*b*) very thin flowing for squirting by a vaporizer; (*c*) concentrated and thick, to be applied by dipping the article to be covered; (*d*) impregnating varnishes to be absorbed by fabrics and the coverings of wires; (*e*) thick foundation varnishes to serve as a support for the cellon insulating varnishes; (*f*) thick pastes hardly suitable for electrical purposes; (*g*) cements for filling holes or forming very thick protective coverings. The layers of cellon obtained from varnishes vary from very hard and inflexible to very soft and pliable. The hardest kinds are the best insulators. In many cases the softer kinds are applied at first and then covered with a coating of a harder kind. All the varnishes adhere well to paper, fabrics and rough wood surfaces, but poorly to metal, stone, cement, etc. They are obtainable in a variety of colors. As the solution has to be made at the present time with liquids of questionable purity it is safer to use only the absolutely neutral varieties for application to copper. Hard varnishes withstand temperatures up to 200° C., but the soft ones soften at 70° C. A number of hints are given as to the choice of varnishes for particular purposes and the methods of applying them.

PREVIOUS to the war Austria did not produce any motor plows, but now this industry has been started in Bohemia and a large trade with the East, chiefly Russia, is being looked forward to. Agricultural machinery of other kinds is also to be manufactured. The prospects of these industries depend largely on the supply of iron and coal. Just now there is a great scarcity of iron, and applications for the release of that metal for the purpose of machinery export have been in most cases refused. The continual deterioration of the coal supply makes it likely that in the coming months the machine industry will also suffer from lack of fuel.

FUEL

Mexico as Source of Petroleum and Its Products*

Holds Second Place Among Petroleum Producing Countries of the World—U. S. Best Market—Development Since 1910 Has Been Tremendous

By R. De Golyer

MEXICO, with its production of approximately 67,000,000 bbl. in 1918, apparently achieved second place among the petroleum-producing nations of the world. The United States, with a marked production of some 345,000,000 bbl., was secure in first place, but it is certain that revolution-ridden Russia could not have produced enough of its normal 60,000,000 to 70,000,000 bbl. to enable it to retain second place.

This position, now gained by Mexico, will not soon be relinquished. The potential production since 1911, the year in which Mexico became an exporter of petroleum, has been far in excess of the actual production, which in the past few years has been limited by the serious tank steamer shortage resulting from the great war. With the ending of the war, the tankers are being rapidly released and many of them are going into the Mexican trade. Production for the present year is likely to be greatly in excess of that of 1918.

There are two general regions in Mexico from which petroleum has been produced—the highly important Tampico-Tuxpam region and the less explored Tehuantepec-Tabasco region. The Tampico-Tuxpam region, which includes the section of the Gulf coastal plain adjoining the ports of Tampico and Tuxpam, is the region from which practically the entire commercial production of Mexico comes at the present time.

The fields of the Tampico-Tuxpam region are divided generally into two groups—those of the Panuco River valley region and those of the southern or Tuxpam region. The fields of the Panuco River valley region, including the Panuco, Ebano-Chijol, and Topila pools, produce heavy viscous petroleum of 10 to 13 deg. Baumé gravity which are used principally in their crude state as fuel oils. The fields of the Tuxpam zone, including Potrero del Llano, Casiano-Tepetate, Cerro Azul, Los Naranjos, Alamo, and Furbero pools, produce lighter petroleums of 19 to 22 deg. Baumé gravity which are the Mexican petroleums used generally for refining purposes.

Export Trade With the United States

Approximately 69 per cent of the petroleum produced in Mexico in 1917, the last year for which detailed statistics are as yet available, was of this grade, and 31 per cent was of the heavier Panuco grade. The proportion of the lighter crude was probably even greater in the production of the past year. Of the 1917 Mexican petroleum production, some 77.6 per cent was exported. Exports for the past year show an even greater percentage and will increase as the Mexican production increases. Of the petroleum remaining in the country during 1917, the equivalent of 5.2 per cent of the total production represents fuel consumed by the Mexican railways and 1.5 per cent represents petroleum consumed principally as fuel in the industry itself. The remaining 15.5 per cent of the total production includes petroleum and products consumed in Mexico, refining losses, increase in storage, if any, etc.

The United States is the greatest single market for Mexican petroleum. In spite of limited transportation facilities during 1917 because of tanker shortage, the United States took petroleum and products from Mexico equal to 65.9 per cent of its entire production. Other nations took 11.7 per cent. The imports of crude petroleum, distillates, and various refined products from Mexico to the United States during that year were equal to more than 10 per cent of the entire production of the United States in its banner year, the one just past.

The benefits resulting from this condition are reciprocal. The United States profits by getting the petroleum, and Mexico, by the nearness of a great market where, as a result of experience acquired from the utilization of its own immense petroleum supplies, American industries are accustomed to the use of petroleum and its products to an extent not equaled in any other country of the world.

Mexican Capacity 1,000,000 Bbl. Per Day

It has been noted that the potential production of Mexico is far in excess of its actual production. It is estimated that the total capaciy of wells already completed in Mexico is more than 1,000,000 bbl. per day. In other words, if the petroleum could be taken care of, so that all the wells could be opened at once, the rate of production would be some eight to ten times the actual present rate. This potential production is slightly greater than the present actual production of the United States. The comparison is likely to mislead, however, unless it is remembered that the production of the United States is an actual proved production and can be maintained for some time by drilling up proved areas, whereas to maintain the actual production of Mexico for a year at its potential capacity would undoubtedly require the discovery of new fields.

We have been so impressed by the unprecedented size of some of the Mexican gushers and by their continued production of large quantities of petroleum over long periods of time without any appreciable decline in amount of petroleum produced daily or in field pressures that we have perhaps overestimated the total amount of petroleum to be secured from any single pool. The explanation of the great gushers seems to lie in the very great porosity of the rock in which the petroleum occurs. It collects in a network of caves and channels previously dissolved out of a bed of very thick limestone by the action of water. This condition allows the petroleum to move about very freely while still underground. Furthermore, the petroleum generally lies over water under an artesian head and as a consequence the field pressure is largely hydrostatic rather than gas pressure, which in most oil fields is the expulsive force causing the oil to flow. Effectively, the result of these conditions seems to be that in Mexico there are deposits of petroleum which can be exhausted with a single well, whereas a deposit of the same size under different conditions of occurrence would require hundreds if not thousands of wells to exhaust it. For comparative purposes it might be noted that there are two wells in Mexico, Potrero del Llano No. 4 and Juan Casiano No. 7, either of which has produced more petroleum than any single field along the Gulf Coast of the United States, while the production of the biggest fields of the Gulf Coast has come from hundreds, if not thousands, of wells, in each instance. The gusher condition in Mexico seems to indicate ease in exploiting rather than such abnormally large pools as have been inferred from the great size of the gushers encountered.

Until 1910, both the actual and potential production of

*Read at the winter meeting of the S. A. E., New York, Feb. 4-6.

Mexico were almost insignificant, in fact not great enough to supply the domestic trade of Mexico itself. Petroleum was imported from the United States and refined at the Minatitlan plant of the Mexican Eagle Oil Co. and the Tampico plant of the Waters-Pierce Oil Co. Small amounts of petroleum were produced at Furbero and in the Isthmus of Tehuantepec and refined by the Mexican Eagle Oil Co. at Minatitlan. A small amount of very heavy petroleum produced at Ebano by the Mexican Petroleum Co. was being topped in a small field plant. The distillate was sent to the Tampico refinery for further treatment and the residue made into asphalt or used as fuel on the Mexican railways. The highly important Dos Bocas and Casiano fields had been discovered, but Dos Bocas had been lost by fire and the discovery wells in the Casiano field had fallen off in production until there was some doubt whether they would be able to supply enough petroleum to run the pipe line then under construction to Tampico.

During 1910, however, the Potrero and Tanhuijo fields were discovered and Potrero No. 4, which has since produced more than 100,000,000 bbl. of petroleum, was brought in. Juan Casiano No. 7, with a record second only to that of Potrero No. 4, was completed and the discovery well in the Panuco field was brought in.

Production Far Exceeds Consumption

The potential production of Mexico thus became so great that she had petroleum far in excess of her own requirements—far in excess of the capacity of transportation systems reaching tidewater and thus making the petroleum available for export. This condition has been permanent since that time, so that to-day the developed production of Mexico is greater than can be carried to tidewater by her rapidly developing pipe-line systems or river-barging equipment. Even if the entire present production could be got to tidewater, it is doubtful whether there are enough ships available to distribute it to the world markets or whether the markets could immediately absorb it. Great fleets of tank steamers to carry Mexican petroleum have been built by the Eagle Transport Co., Ltd., (British), and the Petroleum Transport Co. (American), controlled by the Pearson and Doheny interests respectively, the foremost producers of Mexican petroleum.

The members of this Society are doubtless particularly interested in estimates of the future petroleum supply which can be expected to come from Mexico. The future of supply rather than the past is of greater interest to prospective consumers.

Estimate Production on Past Performance

Estimating petroleum reserves is under the best of conditions a somewhat uncertain business. There was the old method of calculating the oil content of a field or property from the thickness and porosity of the oil-bearing rock. The estimate so secured was modified by a safety factor of 20 to 50 per cent to cover petroleum which could not be mined, and on the resultant guess was based the best estimate as to petroleum reserves. The correctness of such a form of estimate depends largely upon a felicitous selection of the safety factor.

We do a little better now perhaps by estimating the probable production of wells to be drilled or the reserve remaining in wells already producing by comparison with the production of average wells in the same or similar fields. Such a study involves the construction of production curves, the various points on a curve being determined by plotting the amounts produced from a single well or an average well as the ordinates, with the fixed units of time in which produced, arranged consecutively, as the abscissas. Data for the construction of such a graph, to be of any value, must show the changes in the amount of unrestricted production of a given well or average well during various units of time.

We can make estimates of reserves in the Mexican fields by neither method. We have no data as to thickness or porosity of the petroleum-producing formations and consequently cannot use the volumetric method. The bulk of petroleum from Mexico has come from wells of such size that only the production from a restricted flow could be utilized. Production curves constructed on such artificially restricted data as are available under these conditions would be almost valueless. Nevertheless, we can make a rough guess as to the fields already producing in Mexico. It seems fair to assume, on the basis of past performances, that the fields already producing in Mexico indicate what one might call a blocked-out reserve of from a half billion to a billion barrels of crude petroleum.

Geologic conditions indicate that other petroleum fields of greater importance than those now known will yet be discovered in Mexico. So far as exploratory drilling is concerned, the petroleum regions have been but scratched. Not more than 1000 wells have been drilled in all of Mexico since the earliest attempt to discover petroleum. Included in this are a great number of wells drilled for exploitation purposes in fields already discovered, and a number of wells drilled in Tabasco, the Isthmus of Tehuantepec region and various outlying regions.

High Average Well Output

Remarkably few wells are being drilled in Mexico when one considers the amount of petroleum produced. According to official statistics, seventy-nine wells were drilled in 1917, and of them forty-three were productive with an estimated initial output of 235,027 bbl., and thirty-six were dry holes and abandoned. Bardone of the *Oil and Gas Journal* estimates that twenty-three wells were completed in the first half of 1918, twelve of them being producers, with an estimated initial production of 350,000 bbl. For comparative purposes, it might be noted that 1117 wells were completed in Kansas and Oklahoma in the single month of July, 1918. These successful wells have been in proved pools with the single exception of Molina No. 2, which was drilled during the latter part of 1917 and which was the discovery well of a new field.

The greatest needs of the Mexican petroleum industry at the present time are some relief from the continually increasing taxes, which are apparently designed to be confiscatory, and some degree of safety in the petroleum-producing regions in order that much needed drilling of an exploratory nature may be carried on.

The use of Mexican crude petroleum in internal-combustion engines has not yet passed beyond the experimental stage, but more and more crude petroleum is being refined for its light oil products, and this forms an increasingly important addition to the world's supply of engine fuel. The Mexican Eagle Oil Co., Ltd., has refineries at Minatitlan and Tampico and a topping plant at Tuxpam. The Waters-Pierce Oil Co. has refineries at Vera Cruz and Tampico. The Standard Oil Co. of New Jersey has a refinery at Tampico. The Texas Co. has topping plants at Port Lobos and Tampico. The Doheny interests have a topping plant at Tampico and an asphalt plant at Ebano. The Atlantic Refining Co. has a topping plant at Port Lobos.

Little Real Help from Mexico

Only the 19 to 20 deg. Baumé petroleums of the Tuxpam region are refined in quantity in Mexico. All of the refineries and topping plants run it except the Tampico plant of the Texas Co., which tops some Panuco crude, the Ebano asphalt plant, which runs Ebano crude, and the Tampico refinery of the Waters-Pierce Oil Co., which runs a very small amount of Topila crude besides much greater amounts of Tepetate-Casiano, Naranjos and Potrero crudes.

Panuco crude is used mostly for fuel purposes. It is so viscous that after the very small light oil fraction has been removed, the residue can be handled only with the greatest difficulty and by specially designed equipment. Panuco crude is imported to the United States and, after being mixed with Gulf Coast crudes, is successfully refined. One American refinery is reported to crack Panuco crude, thus securing 12 to 16 per cent of gasoline or engine fuel.

The greatest possibilities for future extended uses of Mexican petroleum seem to lie either in the further perfection and more widespread development of internal-combustion engines using very heavy oils as fuel, or in an improvement of refining methods by which heavy oils can be more easily con-

verted into lighter oil. It is likely that both methods will be utilized. In the past several years the continued development and widespread use of internal-combustion engines have created such a demand for fuel that it has been supplied only by great efforts on the part of the producer and refiner of petroleum. Fortunately for the petroleum industry, this demand has set the mark and the internal-combustion engine has not waited to be assured of a source of supply for a fixed number of years in advance.

As to the great advantage of the use of Mexican petroleum in internal-combustion engines over its use as fuel for boiler installations there can be no doubt. In this connection, one can hardly do better than quote from a recent paper by Lord Cowdray, head of the Mexican Eagle Oil Co., Ltd., and affiliated organizations:

Lord Cowdray's Opinion

"It should be stated that Mexican oil, especially refined for use in Diesel engines, is now available for motorships. It is possible that the subject of internal-combustion engines for ships has been discussed with an excess of optimism and led to expectations that have not yet been fully realized, but the most conservative observer cannot fail to be impressed by the solid progress already made in this direction, and the utility of the oil engine for moderate-sized vessels seems to be soundly established. The primary advantage is disclosed in the following figures, giving approximately the comparative consumption by main and auxiliary machinery for various types of marine propulsion.

"It will be seen that the oil engine can claim the lowest consumption; the vessel's radius is considerably increased. These are factors which will inevitably insure a great future for motorships, and the provision of fuel suplies on an ample scale will accelerate their progress."

	Lb. of fuel per hp.-hr.
Steam engine, coal-fired	1.60
Steam turbine, coal-fired	1.30
Steam engine, oil-fired	1.00
Steam turbine, oil-fired	0.82
Oil engines	0.50

Statistics covering the production of petroleum by years since the beginning of the industry have recently been made public by the Petroleum Commission of the Mexican Government. They show the past history of Mexican petroleum and indicate prospects for future increases in production better than can be done in any other manner.

Year	Bbl.	Metric tons

90-95% Lubricating Oil Reclaimed by Army Emergency Process

Complete Gasoline and Oil Consumption Records of Allies

240,000 gal. gasoline used per day by French army.
500 gal. gasoline used per month for airplanes—average, 1 hour per day.
.572 lb. per horsepower hour for airplane.
8 miles per gallon gasoline for staff cars—average, 190 miles per day.
6 miles per gallon gasoline for truck—average, 100 miles per day.

War-Time Necessity Brings About Peace-Time Saving of Fuel

By W. F. Bradley

DURING the month of October, 1918, the Allied armies in France consumed 34,100,000 gal. of gasoline. This was divided among the three nations as follows: France, 14,600,000 gal., England 12,000,000 gal., America 2,500,000 gal. Immediately after the signing of the armistice the gasoline consumption increased owing to the lengthening of the lines of communication. The French army, for instance, consumed 16,860,000 gal. of gasoline during the month of November.

The gasoline consumption of France has steadily increased since 1914. Official figures just issued show that the consumption of gasoline and kerosene for the last 5 years was as follows:

	Gallons
1914	178,500,000
1915	171,400,000
1916	240,000,000
1917	228,700,000
1918	365,400,000

The above figures cover the total consumption of France for both military and civilian uses. Most of the gasoline and kerosene supplied for so-called civilian purposes was used either directly or indirectly for military objects.

For the last three years, 1916, 1917, 1918, no gasoline has been sold to persons not engaged in some military work. For civilian passenger-car service the maximum

allowance of gasoline was a little less than 3 gal. per day, and this amount was only granted to persons using a car in the interests of the nation.

Toward the end of 1917, when the gasoline crisis was at its height, the French military authorities adopted a system of rationing for the army. The officer in charge of each automobile unit was supplied with a limited number of checks which enabled him to draw gasoline from one of the supply depots. In any given period he could not draw more than the quantity of gasoline indicated on his checks. In an army consuming nearly 240,000 gal. of gasoline per day this system resulted in considerable economies.

Although the gasoline shortage in France has frequently been acute, and the strictest economy had to be observed, it is declared that the army was never at any moment handicapped by a shortage of gasoline for its trucks, tanks, passenger cars, tractors, and airplanes.

Army Records of Gas Consumption

French automobile authorities have kept careful records of the gas consumption of all kinds of trucks. Possessing this data, they have found it advisable on several occasions to order a change of carbureter. These records showed, too, where any section or truck train was consuming more than similar groups.

In the aviation service the limit of gasoline and oil consumption was 0.572 lb. per horsepower hour. If this could not be obtained during the official tests the engine was refused. In the American army it was generally estimated that the average consumption of gasoline by an airplane was 500 American gal. per month. This average was based on a general service of both scout and bombing machines.

The French army authorities estimate that staff cars consume gasoline at the rate of 8 miles to the American gallon, and that these cars average 190 miles per day. The average for trucks is 6 miles to the gallon, and the mileage is estimated at 100 per day. In estimating the consumption of gas for airplane squadrons it is assumed that every engine runs for one hour each day.

Practically all the gasoline used in France during the war came from America, and was carried in either American or British tank steamers. The three most important ports at which gasoline was received were La Palice, Le Havre and Bordeaux. Dock facilities were soon found insufficient, and important extensions had to be made.

France was also short of tank wagons when war was declared, the total number at that time being only 470. This number was quickly increased to 680, then to 835. Important orders for tank wagons have been placed in England and America, with the result that France will soon possess 1500, and within a very short time will have a total of 2500 in service, for Germany is obliged to deliver 1000 tankers among the 150,000 railroad cars stipulated in the armistice agreements.

Gasoline Distributed in Cans

The final distribution of gasoline in France, in both military and civilian circles, is in cans containing 1 1/3 gal. Tank distribution by a pump and measuring instruments is practically unknown. Within a few months of the declaration of war, gasoline cans became scarce. Private owners stored cans wherever they could, for they were unable to get deliveries of gasoline if they did not present empty cans in exchange for full ones. At the front, the life of a gasoline can was very short. Because of the rapid destruction of the small cans the automobile service of the army adopted the use of the 13-gal. cans which already existed in the trade, and practically every truck carried one of these cans in reserve within special brackets built on the running board.

The American army kept its main supply of gasoline and oil at the intermediate supply depot established at Gièvras, half way up the lines of communication. This depot, which was entrusted with the task of supplying gasoline to the advance sections, had a reserve of four tanks, each tank containing 500,000 gal. of gasoline. This fuel was handled by the Quartermaster Corps, which distributed it to the Motor Transport Corps, the Air Service Engineers, artillery, and others having need of it.

Aviation Program Threatened Oil Shortage

Early in the war the development of the aviation program threatened to cause an oil shortage. One very wise precaution taken by the French Government was to monopolize all castor beans brought to France. These were delivered to the oil mills at 50 cents per pound. By reason of this measure very little castor oil got to the open market, but where a supply was obtained the usual price was from $1 to $1.50 per pound.

Early in 1916 a chemist attached to one of the States Laboratories discovered a process by which castor oil could be filtered and refined in order to render it fit for further service in aviation motors. This process was brought to the attention of the States Aviation authorities, who refused to be interested. Somewhat discouraged, the inventor brought his process to the notice of M. Meurisse, a press photographer, who for a number of years had acted as AUTOMOTIVE INDUSTRIES representative in France.

M. Meurisse, being acquainted with all the automobile manufacturers, endeavored to secure used oil from them in order to treat it by this process. Merely as a personal favor, and without any hope that the oil would be regenerated, one of the manufacturers delivered 300 gal. of used castor oil to him.

This was refined in accordance with the process invented by the chemist, returned to the factory, and used in an engine undergoing its 50-hour test at full load. Judging from the state of the engine after this test, the regenerated castor oil was equal to new.

Castor Oil Reclaimed

Aviation engine manufacturers were soon convinced that this process was to their advantage, and measures were taken to collect all used castor oil and send it to the factory created by M. Meurisse for treatment. In less than one year practically all the aviation engine manufacturers in the Paris district were sending used oil to be reclaimed.

The Gnome Co., for instance, fitted oil collectors around their engine test benchstands, so that all the oil thrown out of the exhaust could be collected.

Renault was one of the biggest users of this process. He gave orders that the base chambers of aviation engines should be emptied after two hours running under full load and that the oil thus obtained should be sent out for treatment. As the cost of this process was only 7½ cents per gallon, a real economy was effected.

The practice of using oil to destruction, previously done, was risky, for it sometimes happened that an oil was used too long and bearings were burned out in consequence. By giving orders that no oil should be used for more than two hours' steady running all danger of burned-out bearings was eliminated.

In all, about 53,700 gal. of castor oil were treated by this process during the war for the Renault Co. Other firms adopting this process were Hispano-Suiza, Clerget, Darracq, Brazier, Clément-Bayard and Mayen.

After this regenerating process had been adopted by the manufacturers the army became interested. A gen-

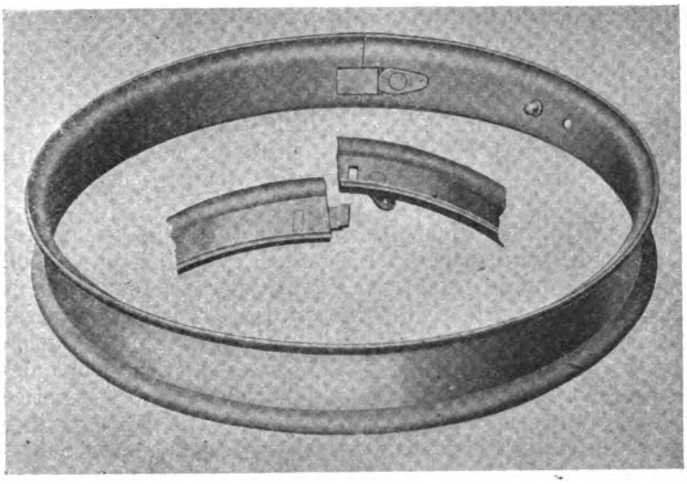
New Stanweld No. 76 Rim

Cam Locking Device Retained—New Design in Accord with Recently Adopted Rim Standards—Large Wedges Insure Proper Alignment of Rims



No. 76 Stanweld rim, which conforms to S. A. E. standards

A NEW standardized rim, referred to as the No. 76, has just been announced by the Standard Parts Co., Cleveland, Ohio. This rim has been designed in conformity with recently adopted rim standards and besides embodies features which are exclusive with the Standard Parts Co. One of the features for which considerable importance is claimed is that the valve stem hole is quite a distance from the split, which prevents injury to the stem when the rim is being manipulated.

No change has been made in the cam locking device, which has long been a feature of Stanweld rims. This locking device is claimed to be thoroughly efficient and easily operated, though it is exceptionally simple in construction.

The wedges holding the rim in place have a large bearing surface, which tends to keep the rims in proper alignment on the wheel and to prevent unnecessary wear of tires. Another advantage resulting from the large bearing surface of the wedges is that the annoying squeaking of rims is entirely eliminated. The wedge nuts are self contained, which simplifies the removal and application of the rims and prevents loss or misplacing of the nuts. The rims are claimed to be exceptionally light and strong.

Farm Tractors in France

ACCORDING to an article in *La Technique Modern*, the farm tractor tests held at La Verriere and Mesnil-Saint Denis (Seine et Oise) last September once again drew attention to the desirability of increasing the cultivation of the soil by means of tractors and of developing the manufacture of such tractors. This article describes the machines of French construction.

Power farming is very necessary in France, owing to the low birth-rate, the constant migration from the country to the towns, and the serious diminution of labor caused by the war. A table is given showing the results obtained in tests made before 1913 and others carried out between 1913 and 1917. The summary of these shows that the average resistance of the soil to a turning effort is as follows:

For light soils, 45 kg. per square decimeter; for average soils, 55 kg.; and for heavy soils, 70 kg. This corresponds to 6.4, 7.8 and 10 lb. per square inch. From the tabulated figures the author deduces that the share of a plow turning a furrow 0.33 x 0.18 m. (13 x 7.1 in.) in section will require a mean tractive effort on the plow of 270 kg. (594 lb.) for light soils; 330 kg. (726 lb.) for average soils; and 420 kg. (924 lb.) for heavy soils. Experience with foreign tractors, especially American, although they have given extremely valuable results in war time, has clearly shown that they are not well adapted for work upon French farms, and French tractors rationally constructed to suit the local conditions should give much better results the author says.

Benzol in Great Britain

A NATIONAL BENZOL ASSOCIATION has been formed in Great Britain to encourage the use and organize the distribution of benzol as a motor fuel and for other industrial purposes. Among the objects of the association are the following: (*a*) To interest automobile users and others in benzol as a motor fuel; (*b*) to sell and distribute motor benzol, whether wholesale or retail, and to obtain for it a fair market price; (*c*) to standardize motor benzol, and to carry on, assist and promote investigation and research with a view to its improvement. The association is to consist of motor benzol producers whose businesses are situated in the British Isles and are subscribers to the association.

Castor Beans in Central America

THE extraordinary demand in the United States a few months ago for castor oil as an engine lubricant created a great deal of interest throughout Central America, where the climate and soil are well suited to the production of castor beans, according to a trade report received here.

A considerable number of plants grow wild in a few places, notably Antigua in Guatemala. This wild production had been utilized in past years by pressing out small quantities of oil for local consumption. In Salvador, Nicaragua, and Costa Rica many planters decided to take up the cultivation of the castor bean in a systematic way, and several of them entered into contracts with importers in the United States for the year's crop.

In Nicaragua two large contracts were signed, aggregating 126,000 bushels. The total crop in that country will probably be about 200,000 bushels. The Nicaraguan crop was planted at the beginning of the rainy season, and harvest began in the early part of December. The Costa Rican farmers planted somewhat later; their fields are not yielding. The variety planted in Nicaragua was a large white seed, while in Costa Rica a medium-sized red seed was preferred.

While the demand has fallen off noticeably since the signing of the armistice, it is probable that Central America will continue to grow castor beans for export. Planters seem to think that it would pay to grow castor beans if the price were from 4 to 5 cents f.o.b. port of departure. They have learned that a close stand of castor plants kills out weeds, leaving the land in excellent condition for planting coffee, beans, corn, or rice.

ON the recommendation of the Road Board the British Government has decided to make special grants to the amount of $50,000,000 in aid of road construction work. Of this sum about $9,000,000 will be provided out of the road improvement fund and the rest drawn from the National Exchequer. In making this decision the Government was influenced by a consideration of the fact that heavy extra expenses will fall upon highway authorities in the near future in connection with work on roads and bridges, as the result of higher prices, lack of materials, shortage of labor and difficulties of transport.

Bombing Work of the British Independent Air Force

Specially Organized to Bomb German Industrial Centers — Made 142 Raids Between October, 1917, and June, 1918—Preparations for Long Distance Raids Complete When Armistice Was Signed

LONDON, Jan. 28.—If the war had continued through the summer and fall of 1919, the work of bombing aircraft squadrons on the western front would have been carried much further than it was. The extensive bombing program of the British, who took the lead in this work, was just getting into shape when the armistice came round, and the final chapters of the work will never be written.

The value of large planes for day and night bombing was not appreciated before the Handley-Page long-distance trip from London to Constantinople in July, 1917, when it made the trip to destroy a Turkish battleship, and succeeded. That trip carried conviction into the hearts of those controlling the Royal Air Force, and the reasoning was that if so much could be done with an experimental machine what might be accomplished with squadrons of perfected machines employed in day and night bombing over the manufacturing cities in the Rhine Valley.

Planned to Bomb Berlin

A comprehensive bombing program was decided upon, and in October, 1917, a few squadrons of bombers were in the zone of Nancy, which was the nearest point to the Rhine Valley from which to launch an attack. From October, 1917, to June, 1918, 142 bombing raids were carried out, 57 of which were over Germany, the remainder being over portions of France held by the Huns. This work was so successful, in spite of bad fall and winter weather, that it was decided in May, 1918, to organize a separate air force to carry out this bombing work. Accordingly, there was formed in May, 1918, what is known as the Independent Air Force, which assumed complete charge of day and night bombing, and had within its organization special pursuit or single and two-seater fighting machines to escort the bombers and fight off the Hun chaser planes that attempted destruction of the bombers.

This great bombing plane campaign was just approaching its really aggressive stages in November, and had the armistice been delayed a month there would have been squadrons of huge bombers that were built to carry the program right to Berlin. Huge machines were being rushed to completion in many British factories and some of them had been tested out only a few days before Nov. 11. One of these was a huge Handley-Page biplane fitted with four Rolls-Royce engines, two on either side of the single fuselage, and spaced between the wings. The engines on each side are mounted in tandem and carry two propellers, one tractor and one pusher. This plane carried forty passengers in its test trip over London, and it had fuel capacity to reach Berlin and return to the aerodrome in Northeastern France.

Although the Independent Air Force was just in its swaddling garments when peace came, it had from June, 1918, to Nov. 11, 1918, established a record that gives indications of what might have been expected by the autumn of 1919.

From June 6 to Nov. 10 there were dropped 550 tons of bombs in day and night bombing, 160 tons by day and 390 tons by night. Of this, 220½ tons were dropped on enemy aerodromes, the aim being to destroy as many of the enemy machines as possible so they could not be used to attack the bombers. There was a heavy destruction of Hun planes by these attacks, yet in the same period not a single British bomber was destroyed by Hun attacks on British aerodromes.

In this dropping of 330 tons of bombs on German manufacturing centers in the Rhine valley and beyond, the general plan was to bomb a great many manufacturing centers rather than attempt to completely destroy one or two centers, in order to disperse the German system of defense requiring them to provide certain protection for all of their cities rather than furnishing complete protection for a few at a time and shifting the forces as the attack shifted.

In this way the British Independent Air Force bombed over forty cities including Cologne, Coblenz, Frankfort, Heidelberg, Karlsruhe, Mainz, Mannheim, Luxemburg, Stultgart, Worms, Wiesbaden and other places.

The first great essential in this work was extending the flying radius of the machines so that they could remain 5¼ hours in the air. Many machines when they reached the aerodrome back of the front had only 3¾ hours' fuel, and it was necessary to rebuild their fuel systems to give over 5 hours' capacity.

Record Bombing In August

Many long-distance flight records were established, and from month to month during the summer of 1918 these distances were increased. The following tabulation shows how distances steadily increased from 272 in June, 1918, to 320 miles in October, 1918, in day flying. The range of night flying increased from 240 miles in June to 342 in August. Here are the figures:

	By day Distance out and back	By night Distance out and back
June	272 miles	240 miles
July	272 "	300 "
August	330 "	342 "
September	320 "	320 "
October	320 "	272 "

August was the best month for both day and night bombing, as in September and October the rains and fogs cut distances down.

The machines used in this bombing work were constantly being changed from its start in October, 1917,

up to November, 1918. The work started in 1917 with the following squadrons:

One squadron DH4, 275-hp. Rolls Royce.

One squadron FE2B, 160-hp. Beardmore.

One squadron Handley Page, 375-hp. Rolls Royce.

In spite of the very severe winter of 1917-1918, this force carried out its 142 raids between October and May, and bombed such cities as Mannheim, Mainz, Coblenz, Cologne and Stuttgart. Long-distance raids were made on Namur and Liege in Belgium.

In the summer of 1918 the force was increased by the following squadrons:

May 23—One squadron, DH9, B. H. P. engine
Aug. 9—One squadron, Handley-Page, Rolls Royce engine
Aug. 19—One squadron, Handley-Page, Rolls Royce engine
Aug. 31—One squadron, DH10, Liberty engine
Sept. 22—One squadron, Sopwith Camel

Escorts for Bombing Squadrons

A squadron was not pushed in bombing work the day it arrived at the aerodrome, but was given three weeks of final training, which it was only possible to carry out at the front.

The general scheme of bombing was that the bombing planes should proceed straight from the aerodrome to their objective, not deviating for any reason. To make this possible the squadron of Sopwith Camels was a fighting escort. These chasse machines had a normal fuel range of slightly over 2 hours, and they had to be rebuilt with fuel capacity for 5½ hours. It would have been suicidal to send the laden bombers without the protecting scouts, which scouts had to be prepared to accompany them the entire distance. This was particularly true of day bombing.

At the start the enemy was not prepared to adequately resist the British bombing program, and it was not until June, 1918, that the Hun planes were coming out in heavy squadrons to resist the British. In August it was necessary at times for bombing squadrons to fight every mile of the way from the aerodrome to the objective and back home. It was necessary to maintain formation accurately, as the Boche could cut off at his leisure every machine that had to drop behind its formation. They invariably concentrated their attacks on the rear machines, and if even a spark plug failed, necessitating a lag behind the formation, it meant a victim for the Boche. In all, 100 British planes were lost, the pilots either being shot down or the plane having to land out of control.

Railroads Vital Points

In this bombing work the British concentrated on railroad lines, stations and storehouses. After these came blast furnaces. The Boche was short of rolling stock, and destroying his railroads made the moving of food and munitions more difficult. Railroad lines are good targets at night, as are blast furnaces. The amount of destruction in blast furnaces was small per bomb that found its target, but they were good targets.

A complete intelligence department was organized to gather information and prepare maps for the work. In this way the most thorough information on all targets, such as gas factories, airplane factories, engine factories, poison-gas factories and railroads, was supplied with detail maps of each target, this work being done by day and night reconnaissance machines.

Long-distance bombing work requires the utmost determination, as a change of wind completely upsets all calculations that may have been made before starting. It requires fine judgment on the leader's part to know, if he perseveres to the objective, whether he will have sufficient fuel to carry the formation home again safely. This will be realized when it is pointed out that on several occasions the machines with only 5¼ hours' fuel supply were out for that time; in one case a formation was out for 5 hours and 30 minutes, and it only just managed to clear the front-line trenches on its homeward journey. A miscalculation of five minutes would have lost the whole formation.

Ceiling was of more importance than speed for long-distance day bombing work. It was essential that squadrons should fly as high as possible, and it soon became apparent, as already stated, that the two squadrons with the 200-hp. B. H. P. engines had not sufficient power for this long-distance work. One squadron was re-equipped with D. H. 9a machines with Liberty engines in November, before the signing of the armistice, and the second squadron had started re-equipping.

Major General H. M. Trenchard, who commanded the Independent Air Force of the R. A. F. in his detailed report on the bombing work has given many incidents which show the risks taken and the difficulties to be overcome. No more efficient general could have been selected for this work, and from the start he took hold and started building up the force along a definite plan rather than changing the schemes from week to week as conditions seemed to indicate. In his report he outlined his general policy as follows:

"It was necessary for the B. E. F., (British Expeditionary Force) to have enough aircraft to hold and beat the German aerial forces on the western front. Bombing of Germany would be a luxury until this were done, and once this were done then bombing became a necessity. That is to say, it became necessary to strike the German army in Germany and to strike at the most vital point—its source of supply.

"In using the Independent Air Force for this purpose I was faced with two alternate schemes of campaign:

"1—To attack as many of the large industrial centers as possible to reach with my machines.

"2—A sustained and continuous attack on one large center after another until each was destroyed, the industrial population having to go to other cities.

"The first plan was decided upon.

"The weather in June, July and August was extremely favorable for long-distance bombing, but in September, October, and the first week of November, it could hardly have been worse. Day after day attempts were made to reach the long-distance targets, but the wind was generally too strong. If there was no wind there was heavy rain and fog by day and dense mists by night. Frequently the nights were perfect, but dense mists covered the ground and made landing impossible and also hid the targets.

"I also recommended that the proportion of day bombing squadrons in the force should be slightly larger than that of night bombing squadrons, as I considered that, although day bombing squadrons suffer higher casualties than night bombing squadrons, at the same time, if day bombing is excluded, at least four-fifths of the value of night bombing must necessarily be wasted, owing to the fact that the enemy can then make his arrangements to work by day and live at a distance by night, and take many other similar defensive steps. Also, if the bombing had been carried out exclusively by night it would not have caused the enemy to make such a large use of his men and material in defensive measures, and therefore it would not have affected the western front to such an extent as it did. Though night bombing is

the safer, many mistakes are made at night in reaching the locality it has been decided to bomb.

Those portions of General Trenchard's report dealing with individual attacks read like chapters from fairy tales. Mannheim, the great manufacturing city where Benz cars and planes are made, was the objective of many attacks.

One formation of bombers was attacked by forty Hun fighting scouts when over the city. Two of these were shot down and three others went down out of control. It required 5 hours and 30 minutes for this trip, but so short of fuel were the fliers that they just got over the trenches on the home trip, and did not reach the aerodrome, the fight over Mannheim consuming quite some time.

Mannheim Attacked Frequently

In another Mannheim raid, in August, twelve DH4 bombers were attacked just as they reached Mannheim by fifteen Boche fighting planes. The British formation dropped to within 6000 ft. of the city and dropped all their bombs. The formation leader was shot down, and in the melee three Hun planes were shot down. Ten planes in the formation dropped their complete loads, and seven bursts on a factory were observed and four fires started. A direct hit was also made on a new factory building. Two of the formation had to land before they recrossed the German lines.

Another night two Handley-Page bombers attacked the Balische Anilin & Soda Fabrik in Mannheim and indulged in a spectacular attack, typical of night bombing. The Handley-Pages left their aerodrome at eight o'clock, and when 5000 ft. over the target one pilot shut off his engine and glided down on the factory. The searchlights at once picked him up and held him in their beams while the anti-aircraft barrage was put up. The machine continually changed its course, but could not shake off the searchlights, and the pilot was completely blinded by the glare. At this moment the second machine glided in, with its engine almost stopped, underneath the first machine, got immediately over the works, below the tops of the factory chimneys, and released its bombs right into the works. The searchlights at once turned on to this machine, freeing the first machine from their glare. This machine then turned and made straight for the works as low as the second machine, among the chimneys, and released its bombs. The searchlights were turned almost horizontally to the ground and the anti-aircraft guns were firing right across the works and factories almost horizontally. In spite of this the two machines remained at a low altitude, and swept the factories, works, guns and searchlights with machine-gun fire. On the return journey both of these machines passed through rain and thick clouds, while lightning and thunder were prevalent throughout the trip.

Direct Hits on Factories

On Sept. 7 eleven machines of one squadron, followed by ten machines of another, made an almost simultaneous attack on Mannheim, where bombs were dropped with excellent results on the Badische Anilin and Soda Fabrik. The first squadron obtained at least eight directs on the factory, but the results of the second squadron could not be observed owing to the mist and smoke. Both squadrons were attacked on the outward and return journey, and over the objective, by superior numbers of hostile aircraft.

One squadron was attacked by six hostile machines 15 miles over the lines. These were driven off. Ten hostile machines attacked about 15 miles over the lines. They were also driven off. Fifteen hostile machines then attacked over the objective. After dropping bombs the formation turned toward the hostile machines, which apparently disconcerted them, as they became scattered. On the return journey several enemy scouts kept up a running fight. One scout, attacking from in front, was driven off by the leader's observer firing over the top plane.

The other squadron was attacked at a long range 15 miles over the lines. The enemy were driven off. Fifteen hostile machines heavily attacked over the objective and followed the formation back for 70 miles. Near the lines the formation was again attacked by seven hostile machines. Over two tons of bombs were dropped at Mannheim in this raid.

On the night of Sept. 16-17 seven Handley-Page machines were missing. Five of these, detailed for Cologne and Mannheim, were probably unable to return in the face of a strong southwesterly wind, which increased after the machines had left the ground. The missing machines undoubtedly attacked various objectives well into Germany before they had to land. It was reported that one machine landed in Holland with engine trouble after having dropped its bombs on Bonn, and was interned.

Enemy Attacks Frequent

On Sept. 25 Squadron A dropped over 1½ tons of bombs on Frankfurt. They were opposed by a large number of hostile machines, two of which they destroyed. Four of our machines did not return, and in addition one observer was killed and one observer and one pilot were wounded. This was the first long-distance raid carried out by this squadron.

On the night of Oct. 21-22, machines attacked the railways at Kaiserslautern in very bad weather. Several 1650-lb. bombs were dropped, but bad visibility obscured the results. One very large fire and five smaller ones were observed, and all these fires were seen to be still burning when the town was lost sight of in the mist.

A few other examples will serve to visualize the character of this bombing work. On the night of June 29-30, Handley-Page machines were ordered to attack the chemical works at Mannheim. Owing to the weather conditions, only one machine reached the objective, on which it dropped its bombs. This machine, on the homeward journey, failed to pick up its aerodrome, and landed no less than 160 miles southwest of the aerodrome undamaged.

On July 5, 12 machines set out to attack the railway sidings at Coblenz. Shortly after starting the squadron passed over thick clouds and steered its course by compass, but the target was obscured by clouds. The leader turned, with the intention of attacking Karthaus, but as he turned the anti-aircraft barrage over Coblenz opened. Through a small hole in the clouds he could see a portion of the target, and the formation followed him and released their bombs.

On July 31, planes went out to attack Mainz. They encountered 40 hostile scouts south of Saarbrucken. Fierce fighting ensued, as a result of which four of our machines were shot down. The remaining five machines of the formation reached Saarbrucken and dropped their bombs on the station. On their way home they were again attacked by large numbers of hostile scouts, and suffered the loss of three more of their number.

On Aug. 11 a squadron attacked the station at Karlsruhe, in spite of bad weather conditions, causing a heavy explosion in the station and scoring many direct hits on the railway sidings. In the course of fighting one of our machines was brought down and three of the enemy's machines were driven down out of control.

The FORVM

An Analysis of the Hotchkiss Drive

By A. W. Happel

THE writer was very much interested in the article "Analysis of the Hotchkiss Drive" by O. M. Burkhardt, appearing in your Jan. 23 issue. Upon looking it over carefully I encountered some statements which I shall presently disprove.

Let us start with the spring loads as given for the 20,000 lb. spring supported Hotchkiss chassis when driving on low gear.

Mr. Burkhardt calculates that we have spring loads as follows:

On front springs	4,250 lb.
2 rear springs, front eyes at 6458	12,916 lb.
2 rear springs, rear eyes at 3938	7,867 lb.
Total	25,042 lb.

Now our chassis weighs only 20,000 lb. above springs and will, accordingly, due to the spring upward reaction, develop, considerable, aeronautic tendencies, if Mr. Burkhardt's figures are correct. It will be interesting, therefore, to go over this case again, using the same notations and load distribution as in the above-mentioned article.

We soon discover that the statement "$W_r'' = 15{,}750$ lb., Fig. 2," is obviously wrong, since P' applied in the upward direction and between the front and rear wheels must reduce the load on *both the front and rear* springs. Mr. Burkhardt's error is made in assuming P'' as acting on the rear spring, while it actually finds its reaction between wheel and ground.

We, therefore, derive the correct value for W_r'' from the formula.

$$W_r'' = W_r - P_r' = 15{,}000 - 1770 = 13{,}230 \text{ lb.}$$

In going over to the Hotchkiss chassis, Fig. 3, it is wrong to assume that the loads remain the same as in the previous case, in spite of shifting the point of torque reaction.

We actually have the following loads for this case:

$$P_f' = \frac{P' \times 25}{168} = \frac{5040 \times 25}{168} = 750 \text{ lb.}$$

$$P_r' = \frac{P' \times 143}{168} = \frac{5040 \times 143}{168} = 4290 \text{ lb.}$$

$$W_r'' = W_r - P_r' = 15{,}000 - 4290$$
$$W_r'' = 10{,}710 \text{ lb.}$$
$$W_f'' = W_f - P_f' = 4250 \text{ lb.}$$

Proof:

(a) Forces in upward direction:

Spring reaction W_r'' =	10,710 lb.
Spring reaction W_f'' =	4250 lb.
Torque reaction P' =	5040 lb.
	20,000 lb.

(b) Forces in downward direction:

$$W = 20{,}000 \text{ lb.}$$

We see everything is nicely balanced.

To determine the actual loads on the rear spring eyes, it is best to remember that the rear axle also must be in equilibrium; *i. e.*, we must have:

$$\Sigma M = 0$$

We have a clockwise moment of

$$T \times 20 = 126{,}000 \text{ lb.-in.}$$

A counter-clockwise moment of

$$P' \times 25 = 126{,}000 \text{ lb. -in.}$$

Any additional moments, due to frame load, must, therefore, of necessity be balanced, if a symmetric spring is used, *i. e.*, each spring eye will receive:

$$\frac{10{,}710}{4} = 2677.5 \text{ lb.}$$

We then have for the load on the rear spring front eye:

$$\frac{5040}{2} + 2677.5 = 5197.5 \text{ lb.}$$

and for the load on the rear spring rear eye we get 2677.5 lb.

The summation of vertical forces will, therefore, be:

Upward: Reaction of front springs	4250 lb.
Reaction of 2 rear springs, front eyes at 5197.5	10,395 lb.
Reaction of 2 rear spring rear eyes at 2677.5	5355 lb.
Upward total	20,000 lb.

Downward: $W = 20{,}000$.

Going over to the brakes we hear that in the case of the chassis shown in Fig. 2 the rear springs are loaded less than ordinarily when the brakes are applied. Analyzing this claim we find that, using Mr. Burkhardt's figures, we have a torque reaction of:

$$P' = \frac{180{,}000}{50} = 3600 \text{ lb., downward.}$$

Of course, the springs have to carry this additional load. Reaction P'' cannot act on the spring for even if—

$$P'' > W_r''$$

it will only lift the rear end of the chassis off the ground but cannot increase our spring load.

$$P_r' = \frac{3600 \times 118}{168} = 2530 \text{ lb.}$$

$$W_r'' = 15{,}000 + 2530 = 17{,}530 \text{ lb.}$$

i. e., considerably *more* than when driving on low gear.

The maximum spring eye load, then, for this chassis is

$$\frac{17{,}530}{4} = 4382.5$$

Front axle load

$$W_f'' = 5000 + \frac{3600 \times 50}{168} = 6070 \text{ lb.}$$

A summation of the forces for this case is then as follows:

Upward:

Reaction of front springs	6070
Reaction of rear springs	17,530
Total	23,600

Downward:

$$W = 20{,}000 \quad P' = \frac{23{,}600}{3600}$$

Turning now to the analogous Hotchkiss chassis, Mr. Burkhardt's figures again prove erroneous if the actual moments of forces are analyzed. Referring to the accompanying figure, we find:

$$P' = \frac{180{,}000}{25} = 7200 \text{ lb.}$$

$$P_r' = \frac{P' \times 193}{168} = 8270 \text{ lb.}$$

$$W_r'' = W_r - P_r' = 15{,}000 - 8270 = 6730 \text{ lb.}$$

Or, per spring eye,

$$\frac{6730}{4} = 1682.5 \text{ lb.}$$

Then, as before, load on rear spring front eye: 1682.5.
Load on rear spring, rear eye,

$$1682.5 + \frac{7200}{2} = 5282.5 \text{ lb.}$$

Load on front axle,

$$W_f'' = 5000 + \frac{7200 \times 25}{168} = 6070 \text{ lb.}$$

Summation of vertical forces for this case:

Upward: Front spring reaction	6,070 lb.
Reaction of 2 rear spring front eyes	10,565 lb.
Reaction of 2 rear spring rear eyes	3,365 lb.
Total upward forces	20,000 lb.

Downward:

$$W = 20,000.$$

We see, therefore, that there is not so great a difference in the spring loads of the two types of chassis as Mr. Burkhardt imagines, for, using his own figures, we find a deflection:

$$d_1 = 4 \times \frac{1650}{4382.5} = 1.50$$

and

$$d_2 = 4 \times \frac{1650}{5282} = 1.250$$

The above calculations do not consider moments due to location of axle relative to spring top leaf, etc., although these must be considered in a full analysis of the case as Mr. Burkhardt states.

It appears, therefore, that we have in the Hotchkiss drive not only a much simpler, less expensive and very much lighter mechanism, but also one which will show no difference in riding qualities, for we have only to increase our spring travel from 4 in. to

$$\frac{4 \times 1.50}{1.25} = 4.80 \text{ in.}$$

to be able to use the same spring rate, pounds per inch, as in the torque rod chassis.

There need not be any fear of faulty action of the brakes if they are correctly designed, and there is no excuse for not designing them so. In fact, we have the great advantage of cushioning a sudden application of the brakes or driving torque.

Spring loads can be reduced by increasing the length of the springs. The earmarks of a good Hotchkiss chassis are, therefore, adequate spring travel and long springs. A still further reduction on spring loads can be made by the use of under-slung springs—a favorite design on passenger cars.

The torque rod, on the other hand, when brakes are applied, imparts to the frame an important additional load; in our case almost two tons (3600 lb.). This is equivalent to a sudden overload of 36 per cent. It is evident, therefore, that it is much more dangerous to overload a torque rod chassis than a Hotchkiss drive chassis.

In passing it might be interesting to have the views of the advocates of torque rods on the bearing loads on the rear end of the torque rod which are extremely high and not easily taken care of.

In conclusion, I agree with Mr. Burkhardt that there is no need of hypotheses in spring design but all loads can be accurately determined by mathematical deductions.

Government Operation of Tractors Successful

GREAT BRITAIN has inaugurated a plan for Government operation of farm tractors in Yorkshire, England, whereby the machines work in units at fixed charges. Five units are operated, each comprising 10 tractors, 10 2 or 3 bottom plows, 4 cultivators, 3 or 4 binders, 2 rollers, etc. The tractors used are of two types, of 20 hp. each. Minimum charges have been established, according to the report, by the West Riding War Agricultural Committee as follows:

Plowing—Light land (3-horse work), $5.48 per acre; medium land (2-horse work), $6.69; heavy land (3-horse work), $7.91; heavy land (4-horse work), $9.13.

Cultivating—Disk or drag harrowing, $2.74 to $3.65 per acre; breaking stubble after harvest with cultivator, $3.16 to $4.87 per acre; rolling if 2 rollers are drawn, 85 cents per acre.

Harvesting—Reaping, with self-binder, field 10 acres and over, $3.65 per acre; 5 to 10 acres, $3.89 per acre; under 5 acres, $4.26 per acre; haulage of farmer's binder, $1.46.

"These charges," states the U. S. Consul transmitting the report, "in general work out at substantially below the cost of team labor on the land. While it is true that the British Government in 1917 undertook plowing operations at a minimum of $3.65 an acre, it is now known that this price involved a considerable loss. Even at a minimum charge of $5.48 per acre for plowing, the demand for tractors is greater than ever.

"Perhaps the best testimony to the usefulness of the tractor has been the part it has played in the reclamation of derelict land, of which class there has been a large proportion in the country and which the North Riding War Agricultural Committee has set to work to bring under cultivation. These lands have been widely scattered, and in two districts in particular the task was very difficult. With the aid of the tractor, however, tree roots have been stubbed up, whins cleared, gaps filled, bushes removed, and the land generally prepared. This was all done with the aid of the tractor, and many acres of useful arable land was obtained which was put into wheat.

"Some interesting information furnished by the committee illustrates the part which the tractor has played in increasing the area under cultivation in North Riding. In 1917 motor tractors were used for plowing and cultivating to a limited extent, and were regarded by the farmers as more or less of an experiment. During 1918 the committee had 103 tractors at work, an increase of nearly 70 per cent on those employed the previous year."

Decrease in Iron Ore Production

THE estimated quantity of iron ore mined in the United States in 1918 amounted to 69,712,000 gross tons, compared with 75,288,851 tons in 1917, a decrease of 7.4 per cent. The estimated shipments of ore from the mines in 1918 were 72,192,000 gross tons, valued at $246,043,000, compared with 75,573,207 tons, valued at $238,260,444 in 1917, a decrease in quantity of 4.5 per cent but an increase in value of 3.3 per cent. The average selling value of the ore per gross ton at the mines for the whole United States in 1918 was $3.41, compared with $3.15 in 1917. The stocks of iron ore at the mines apparently decreased from 10,628,908 gross tons in 1917 to 8,139,000 tons in 1918, or 23.5 per cent.

The decrease in output, which was general throughout the country, is probably to be attributed to a combination of circumstances. Industrial conditions were more or less disturbed, the supply of labor was uncertain, and transportation facilities were inadequate, but notwithstanding these handicaps the shipments from the Lake Superior district from April to October, inclusive, 1918, were over 2,500,000 tons more than those for the corresponding period of 1917. Owing to a scaling down of furnace requirements, however, in order to release vessels for carrying grain to Europe, the shipments in November and December, 1918, were nearly 4,000,000 tons less than those made in November and December, 1917. Government control of the entire steel supply, which became effective in June, 1918, undoubtedly regulated the demand for ore, and stocks at mines and lower Lake ports were somewhat reduced, so that the consumption of ore remained about the same as in 1917.

Radical Element Is Destroying Labor Organizations

Organizations Are Too Ready to Disregard Instructions or Counsel of Their Elected Leaders

By Harry Tipper

ATTENTION has been drawn in these articles to the tendency in labor organizations to withhold power from the leaders, or to disregard the instructions of the duly elected executives when such instructions appeared to be contrary to the immediate and local necessity of the branch of the organization involved. Not only is this the case, but there is an ever present tendency for the labor organization in any locality or occupation to follow the radicals, the men who are in favor of direct action.

There are many reasons for this tendency. The labor organization has been based in its traditions upon the promise of advantage to be secured by getting together for the purpose of bargaining with the employer or owner. The labor leader, who has had the responsibility of directing the action of labor in the many intricate and complicated problems with which it has to deal, seeing the danger in many of the proposals, becomes conservative and careful in his attitude. The irresponsible radical is in an excellent position to agitate against the apparent inactivity, or actual obstructionist policy of the leaders as he sees them, and promise all sorts of advantages for adopting the policies he outlines.

This leads to the sharp division which is to be observed in all labor organizations and the statements of labor leaders that we are living above a powder magazine. To the average workman the advantages of belonging to a labor organization are compassed by the actual improvements in hours and wages which are constantly insisted upon.

So soon as these advantages cease to accrue from the organization, no matter how much of value they may have accomplished in past history, the rank and file become dissatisfied and critical, and are likely to question the merit of the payment of the necessary dues. They are likely to insist upon action, and to bring sufficient pressure to bear upon the leaders to force them to some action, whether they believe it is wise or not; or they may decide to act without the regular method of decision through the appointed officers and executive committee.

Danger of Organized Labor Inside the Organization

It is in this constant anarchistic tendency within the labor organization itself that the grave danger of the organized labor movement lies. Were it possible to secure an agreement with labor by conferences with its leaders with which the general body concurred it might be possible to settle some of the problems that confront us. This might be accomplished through agreements between committees appointed by the manufacturers' groups and committees appointed by the labor organizations. This is so far from being the case, however, that it is somewhat absurd to discuss the contingency, except that there exists a general tendency to accept the labor organizations at their face value and suppose that the leaders can obligate the unions as congress can obligate the United States.

The indications of this have been visible for ten years previous to the great war, but that time of stress and emergency brought out the conditions very fully. It is significant that most of the strikes called during the war were called against the demand of the national leaders and such strikes were vigorously denounced by them.

Strikers Taking Advantage of Uncertainty of Time

At this time there is a tendency to call strikes for no other purpose than to seize upon the present uncertainty and fluidity of public opinion to gain various classes of workers without regard to the general effect upon the whole economic structure. There is a definite propaganda going out from labor circles aimed at the probable change in commodity and wage values, but in reality to forestall any action which might result in the lessening of the political power of labor, which has grown so tremendously during the war.

These facts do not keep the manufacturer from observing and taking careful count of the public desire for a different organization of industrial establishments, nor do they justify the sweeping assertion that all labor demands are without justice and should not be encouraged. They really emphasize the necessity for just action and a studious consideration of the whole problem, so that the decision may not be prejudiced by the apparent absurdity of the demands made by some labor organizations, nor stampeded by the propaganda which is issued freely by the radicals on both sides with the definite purpose of using the situation for political and individual advantage without any regard to the fundamental requirements of the case.

Satisfied Workers Want No Interference

The present situation makes clear the impossibility of securing any peaceful and harmonious arrangement between capital and labor in the mass by general agreement between the leaders, and lends force to the argument that it is necessary for the employer to solve the problem for his own establishment and his own employees. This makes it important to examine the records of those establishments which have approached and dealt with this problem by organization changes, and which have placed some of the responsibility upon the workers and instituted some form of profit sharing plan in connection therewith. Particularly is it important that the records be looked up in the endeavor to discover what has happened in those establishments during the turmoil of the past few years and present difficulties. Fortunately it is possible to find this out in conection with some cases where the plans have been worked out for a sufficient length of time to permit of a valuable comparison.

Take the case of a plant in which the method of participation was through a house of workers' representatives,

a senate body of department heads and a cabinet of the general executives. This plant has been referred to in a previous article. During the war there was a general strike in this industry, and after the labor body and employers had failed to reach an agreement the War Labor Board of the government was called in to work it out. All this time this particular plant was working full time with no absences of employees. When the Labor Board was called in the workers in this plant addressed three special communications to Washington requesting that the decisions of the board be considered not to apply to that organization, as the workers there had no intention of striking and were so well satisfied with the plan under which they were working that they did not want it upset by any decision arrived at by the adjustment board. They were not satisfied that the government had wakened to the full significance of the case. In order to further safeguard their own interests they sent a deputation to Washington to wait upon the Labor Board and make sure that they would be left alone to continue as they were.

This is only one instance of the value of a plan whereby the employers and employees get together in the individual organization and work out the necessary plans with respect to that unit, but it is very significant. The conditions were favorable to the worker. The strikers were likely to profit by the wage board's decision, and the stern necessities of the war made the bargaining power of the workers almost unassailable. There was no special attempt made in the organization we are speaking of to give their workers any special advantages or advances in wages. The regular procedure was governing this case. Every inducement which could have acted upon the workers to join the general body in this industry was involved, and only the firm belief in the merits of the plan to which they had subscribed held them to their places. The value of the plan to the owners of that concern cannot be overestimated in this one instance.

Trouble Makers Unwelcome

In another case, the men in one department of the factory asked for an increase of wages through their representative. The board of representatives considered the case and turned the request down with its reasons. After a week or two the matter was brought up again by the same workmen and the reply was that conditions had not changed and the representatives did not feel that they were able to change their previous decision. The matter was brought up a third time and the same answer was given. Then the men went out on strike, and the representatives of the rest of the workmen said, "All right, if you feel that way about it, maybe you had better get out." In two weeks they were all asking for their jobs again. The rest of the plant had gone on, and other men had been secured for the department, because the rest of the workers said, "These fellows are trouble makers. We don't want them back in this establishment."

Here again is an illustration of the worker backing the organization which has convinced him that it is dealing with him squarely, with the books open, and giving him some share in the control of his own conditions. Instances of this sort can be taken from all organizations where this problem has been dealt with from the proper standpoint—that of getting the industrial unit, the individual organization, together on the common basis of sharing the benefits and difficulties, and sharing also in the responsibility for the conditions in which they work. They should make the manufacturer pause a little before casting out plans for industrial organization which may seem to throw away his control, but which in reality give him more control than ever, because it is the solid control of an institution thoroughly organized upon a harmonious basis, where there is a team spirit which makes efficiency possible, and without which it is impossible to get any real efficiency.

A Question of Psychology

Some day the engineer and production manager and the other governing executives will know enough about the motives which govern human action to realize that efficiency is not a matter of machinery, nor is it a matter of the number of motions which must be made to complete a certain job. It is a matter of the relation of the complex mental and physical necessities to the work which it has to perform, and the social surroundings in which it must live and work. It involves a much greater degree of scientific research and development than all the mechanical arts which contribute their share to the necessities of manufacturing. It is not to be secured by the dogmatic attitude of mind which builds upon its own prejudices an unassailable logic, unassailable because there is no possibility of argument with prejudice. It cannot be secured by assuming that any particular form of organization is the correct one for these conditions merely because it was correct forty years ago.

After all, the necessity which is constantly before the manufacturer is production at greater value for less expense, more efficient work for less expenditure of man power. This means an intelligent study of the things which affect the mental and physical capacity of the man, the effect of tradition, the application of the deep seated human desires and the effect of the character of his surroundings upon his work. There are enough experiments in organization to give their practical value from a production standpoint, and they are necessary if we are to have industrial peace.

Book Review

Cost Accounting, by J. Lee Nicholson and John F. De Rohiba. Published by the Ronald Press Co., New York. Five hundred and seventy-six pages, 5½ x 8 in. Price, $6.

This is a comprehensive volume on the subject indicated by the title, by members of a firm of supervising cost accountants. The importance of cost accounting in factory operation has been brought home to a great many manufacturers in recent years who gave it little consideration previous to that time. Much effective educational work along this line has been done by the Federal Trade Commission, with a view to establishing more stable conditions in industries. Another thing that has helped to bring the subject of cost accounting prominently to the fore is the fact that a movement has been launched in various industries to standardize cost accounting methods for the particular industry.

The present volume is an extension of a previous book on the same subject by the senior author, "Cost Accounting; Theory and Practice," which was published in 1913. It has been the author's aim to classify the details of cost accounting so that the reader may get a well defined idea of the forms and records required for each separate operation, and how these forms and records fit into the general system used in any particular establishment. Every feature of cost accounting is gone into in the book and numerous forms are illustrated.

Christensen Starter on Duesenberg Engine

IN the description of the Duesenberg 800-hp. engine which appeared in the Jan. 23 issue of AUTOMOTIVE INDUSTRIES there was shown a front view of the engine which illustrated very clearly the mounting of the starter with which the engine was started while on the test stand. This is the Christensen starter, aero type.

Small Inlet Valves Satisfactory in Overhead Valve Design

British Engineer's Tests Prove High Charging Capacity—Specific Fuel Consumption Largely Independent of R. P. M. and Torque for 50 to 60% of Maximum Horsepower

Fitting Electric Starting and Lighting Units Easiest on Valve-in-Head Designs

PART I

LONDON, Jan. 15—L. H. Pomeroy, engineer of Vauxhall Motors, Ltd., recently read a paper before the Institution of Automobile Engineers here in which he analyzed a series of tests made with two engines of approximately the same size, about 3 liters (90 by 120 mm.). One was a valve-in-head design and the other an L-head with valves side by side in the valve pocket.

The paper was of unusual interest due to several facts that are deeply concerning the British automobile engineer at present. The entire European industry is landsliding to electric starting and lighting, and fitting the starting motor and electric generator on an L or T-head engine is almost impossible, according to Mr. Pomeroy, whereas it is relatively easy on a valve-in-head design.

Valve-in-head engines were not taken up in England because of the noise and the national demand for silence. Now that quiet over-head-valve designs are possible and practical the British engineer, and the French and Italian engineer as well, is taking a new interest in this design, and Mr. Pomeroy's paper took on a new international importance because of this. Italian and French engineers have openly expressed their sympathy for the overhead valve, and the next two years will record many new European designs with this valve scheme.

Test for Average Conditions

Mr. Pomeroy faced the problem in one of the most practical ways possible and carried out his tests to meet the average touring car conditions, rather than racing car or aviation engine conditions.

He used three different diameters of inlet valves on the L-head and valve-in-head engines and proved to his own satisfaction that with the valve-in-head design you can use very small-diameter valves, with high inlet gas velocity and get good horsepower and high fuel efficiency. He satisfied himself that increase in brake horsepower is not proportional to increase in inlet valve area, and that maximum brake-horsepower is largely independent of inlet gas velocity. In his opinion very much higher gas velocities can be used than are common in present-day practice.

The European designer must always keep in mind the fuel economy of his car, and here, too, Mr. Pomeroy has arrived at some interesting conclusions. Fuel consumption is not related directly to inlet gas velocity; in other words, the diameter of the valve does not materially affect the fuel consumption per horsepower hour.

Three different areas of inlet valves were used, 1.8 sq. in., 1.4 sq. in., and 0.7 sq. in. The carbureter setting in each test was not necessarily that for maximum economy, but rather to give easy starting and good road acceleration; in fact the carbureters were tuned up from the point of view of the average driver.

The two engines were practically identical in design except for valve arrangements. In both engines the compression pressures at full throttle were nearly equal in each of the corresponding tests, thus demonstrating that there is no appreciable difference in the charging effect with different valve diameters when the valve lift is kept constant.

Mr. Pomeroy discussed his experimental data under the eight following heads:

1—Inlet gas velocity and maximum brake horsepower.
2—Inlet gas velocity and brake mean effective pressure.
3—Inlet gas velocity and fuel consumption at full load.
4—Inlet gas velocity and fuel consumption at varying loads.
5—Revolution speed and brake mean effective pressure.
6—Revolution speed and fuel consumption at full load.
7—Revolution speed and fuel consumption at varying loads.
8—Fuel consumption per hour for any given brake horsepower, irrespective of engine speed.

The particulars of the two engines tested are as follows:

	Engine A	Engine B
Bore	90 mm.	90 mm.
Stroke	120 mm.	118 mm.
Compression ratio	4.8.1	4.8:1
Inlet valve dia	1.75 in.	1. $\frac{9}{16}$ in.—1. $\frac{3}{8}$ in.—1 in.
Inlet valve area	1.8 sq. in.	1.8 sq. in.
	1.4 sq. in.	1.4 sq. in.
	0.7 sq. in.	0.7 sq. in.
Exhaust valve dia	1.75 in.	1.5 in.
Exhaust valve area	1.8 sq. in.	
	1.4 sq. in.	1.75 sq. in.
	0 7 sq. in.	

Valve Timing	Engine A	Engine B
Inlet valve opens	10 degrees late	0 degrees
Inlet valve closes	47 degrees late	44 degrees late
Exhaust valve opens	65 degrees early	40 degrees early
Exhaust valve closes	17 degrees late	0 degrees

Deduction.—Increase in brake horsepower is not proportional to the increase in valve area; in other words, the small inlet valve is more useful per unit of area than the larger one. The maximum brake horsepower in the normal touring car engine is very largely independent of gas velocity through the inlet valve, and much higher velocities can be used than are common in practice at present.

Mr. Pomeroy in arriving at this deduction analyzed his experimental data as follows:

Tables I and II and Figs. 1 and 2 show the tabular and plotted values of inlet gas velocity and brake horsepower for both engines. The brake horsepowers were measured by a Froude dynamometer. The curves indicate that the brake horsepower is still rising in each engine with the 1.8 and 1.4 sq. in. area valves at the maximum revolution speed of the experiments. From other tests, however, it is known that the maximum brake horsepower shown is very nearly indeed the maximum attained, and can be regarded as such. It will be seen that in engine *A* the increase in valve area from 1.4 sq. in. to 1.8 sq. in. corresponds with an increase in maximum brake horsepower of 4, *i. e.*, from 42 to 46, some 9 per cent. The results in Table I (valve area 0.7 sq. in.) relating to engine *A* indicate a very poor power performance, and are not offered for criticism.

Expressing maximum brake horsepower in terms of valve area for engine *A* we have:

1.8 sq. in. valve...... 6.8 hp. per sq. in. of valve area
1.4 sq. in. valve...... 7.6 hp. per sq. in. of valve area
0.7 sq. in. valve...... 9.8 hp. per sq. in. of valve area

In each case the maximum brake horsepower is attained at speeds between 2200 and 2400 r.p.m. These figures show that the increase in brake horsepower is not proportional to the increase in valve area; in other words, the small valve is more useful per unit area than the large one.

With engine *B* the maximum brake horsepower is the same with both the larger sizes of valves, and is reduced by 20 per cent with the smallest valve of 0.7 sq. in. area.

Expressing brake horsepower in terms of valve area we have for engine *B:*

1.8 sq. in. valve.... 6.87 b.hp. per sq. in. of valve area
1.4 sq. in. valve.... 8.97 b.hp. per sq. in. of valve area
0.7 sq. in. valve.... 14.65 b.hp. per sq. in. of valve area

The maximum brake horsepowers are in each case attained at 2400 r.p.m.

It will be noted that the maximum brake horsepower obtained in engine *B* with 0.7 sq. in. overhead valve is almost the same as that in engine *A* with 1.4 sq. in. valve of side-by-side design, the gas velocities being 220 ft. per sec. and 450 ft. per sec. respectively.

The reasons for this rather striking result arise from considerations which will be developed later.

*Calculated M.E.P. excludes fluid and pumping losses.

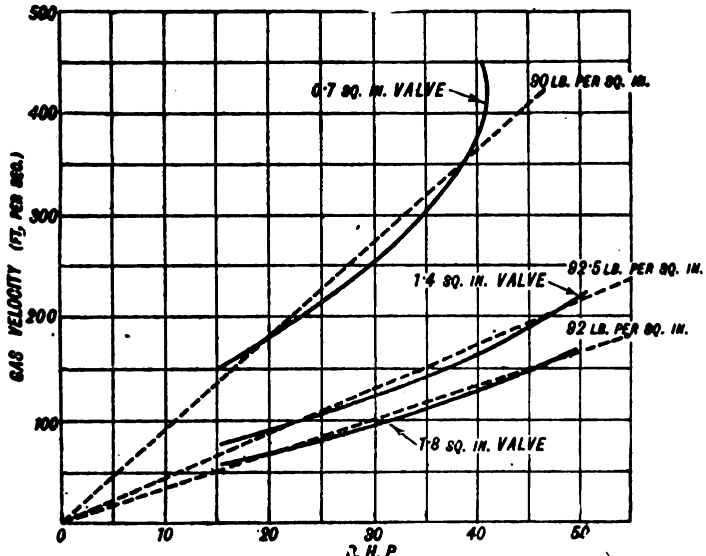

Fig. 1—Plotted values of inlet gas velocity and brake horsepower for engine A

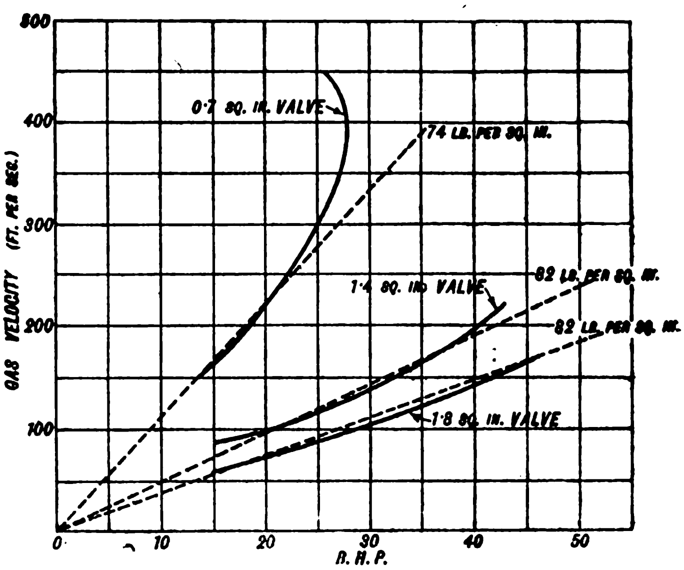

Fig. 2—Plotted values of inlet gas velocity and brake horsepower for engine B

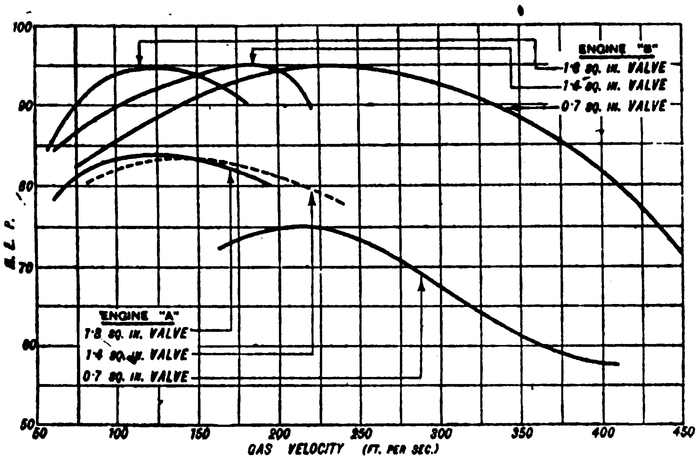

Fig. 3—Tabular and plotted values of inlet gas velocity and brake mean effective pressure for engines A and B

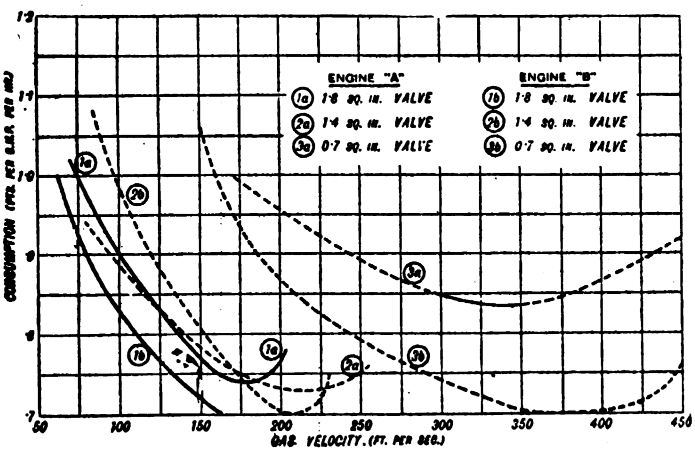

Fig. 4—Tabular and plotted values of improvement of fuel consumption

Further comparison of the maximum brake horsepowers obtained from engines *A* and *B* with valve areas of 1.8 and 1.4 sq. in. respectively show an increase of 10 per cent in maximum brake horsepower for engine *A*, but no increase for engine *B*, the increase in inlet gas velocities in each case being from 167 ft. per sec. to 220 ft. per sec.

The figures show, therefore, that in these engines the maximum brake horsepower obtained is very largely independent of the gas velocity through the inlet valve, and that for *normal touring car engines* much higher gas velocities can be used than are common practice without adversely affecting maximum brake horsepower.

Inlet Gas Velocity Has Little Effect on B.M.E.P.

Deduction—In the valve-in-head engine the effect of inlet gas velocity on brake mean effective pressure is much less than generally assumed, and B. M. E. P. of the order of 95 lbs. per sq. in. can be obtained with inlet gas velocities in the region of 300 ft. per second.

Referring to this Mr. Pomeroy said:

Tables I and II and Fig. 3 indicate the tabular and plotted values of inlet gas velocity and brake mean effective pressure for engines *A* and *B*.

To discuss these figures properly necessitates data as to the mechanical friction losses at the various speeds, so that inlet gas velocity may not be charged with a reduction in brake mean effective pressure due to mechanical friction.

The author has not been able to make such measurements, but data published on the friction losses of similar engines to those under discussion give figures which are probably near the truth.

Thus the *mechanical friction* losses (i.e., excluding pumping and fluid losses) are about as shown in Table IV.

The values of calculated mean effective pressure in Tables I and II are obtained by adding the appropriate allowance as shown above to the figures for brake mean effective pressure.

It will be seen that engine *B* is decidedly better in respect of mean effective pressure than engine *A*, but that in each case the calculated mean effective pressure is fairly steady at the various inlet gas velocities and does not fall off appreciably, i.e., more than about 5 per cent for gas velocities up to 300 ft. per second.

The author suggests that these results, particularly those obtained with engine *B*, show that the effect of inlet gas velocity on mean effective pressure is far less than is generally assumed.

The figures show also that brake mean effective pressures

of the order of 95 lb. per sq. in. can be obtained with inlet gas velocities in the region of 300 ft. per sec.

Fuel Consumption Not Related Directly to Inlet Gas Velocity

A—Full Loads

Deduction—Improvement in fuel consumption is related to increase in engine speed rather than to increase in gas velocity as such.

Mr. Pomeroy analyzed his data:

Tables I and II and Fig. 4 indicate the tabular and plotted values of these quantities for both engines.

The characteristic feature of all the curves is that the consumption per brake horsepower per hour rapidly falls with increase in the inlet valve gas velocity, but rises again with further increase in gas velocity as the upper limit of revolution speed is reached. Further study of the curves shows that the downward path of each curve is approximately inclined to the horizontal in such a way that the improvement per cent in consumption is proportional to the increase per cent in inlet gas velocity. *In other words, the improvement in consumption is related to increase of engine speed rather than to increase of gas velocity as such.* This aspect of the case will be discussed later.

It is well known that turbulence, i.e., violent agitation of the mixture at the instant of ignition, *is essential for both power and economy;* it is usually regarded as a function of inlet gas velocity, so that it is of interest to see if any improvement in fuel consumption can be associated with increase in gas velocity. An examination of the curves in Fig. 4 shows that the same consumption in the different cases is attained with very differing values of gas velocity.

It may be said, therefore, that there is either no apparent increase in efficiency with the higher gas velocities or that there is no apparent decrease in efficiency with the lower gas velocities.

It would seem that, in considering turbulence, inlet gas velocity must be considered in its relation to revolution speed or piston speed, and that there is a certain minimum relation between the two which produces the necessary turbulence for approximately complete combustion at all speeds.

From these experiments it seems reasonable to believe that this minimum is secured with the largest valves used at the lowest speeds of the tests. It will be of great interest if the discussion reveals any experiments of this kind upon similar engines but run at lower engine speeds.

The conclusions formed by the author in considering these results are:

1. That consumption is not related directly to inlet gas velocity.
2. That sufficient turbulence is developed to produce approximately complete and rapid combustion at quite low gas velocities.
3. That the improvement in consumption with increase of inlet gas velocity shown by the curves is related to revolution speed and not to gas velocity as such.

Table III shows the consumption of each engine at varying loads and speeds for each area of inlet valve.

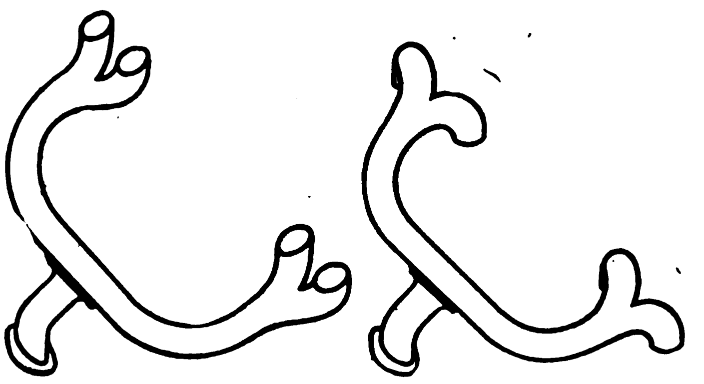
It will be seen that there is no great difference in consumption in each corresponding series of figures relating to the tests with inlet valves of 1.8 sq. in. area except at the lower speeds at 0.6 and 0.4 of full load, where engine *B* is decidedly better than engine *A*. The same remark applies to the tests with inlet valves of 1.4 sq. in. area.

Comparing the tests at 0.8, 0.6, and 0.4 full load when using each size of inlet valve, *it is evident that there is no marked effect which can be attributed to variation of inlet gas velocity.*

For example in Table V:

TABLE V.

		Inlet Valve Areas		
		1.8 sq. in.	1.4 sq. in.	0.7 sq. in.
Average consumption of engine *B* in pints per B.H.P. per hour between 800 and 2400 revs. per minute	Full load	0·82	0·86	0·83
	0:8 full load	0·78	0·78	0·76
	0:6 full load	0·82	0·85	0·88
	0:4 full load	0·94	1·06	1·02
Average gas velocity, ft. per second		111	146	300



Figs. 5 and 6—Carbureters used on each engine were similar in each case

Those who are accustomed to making measurements of fuel consumption in bulk, so to speak, will appreciate the fact that the small variations shown as between the one valve area and another are easily accounted for by errors in measurement.

The fuel consumption measurements were made by running the engine for a period required to use 0.5 pint of fuel, and as a rule the figures given are the average of three runs. The difficulties, however, of keeping the engine speed and load constant were very appreciable at the lower speeds, as these occupied much time.

The author would point out that the consumptions at full load are higher than those at 0.8 full load. This increase in consumption at full load, compared with 80 per cent of full load, occurs so frequently that it cannot be accidental. It is not in the author's opinion easily explicable, and he hopes the discussion will throw some light on the point. It does not appear to be connected with revolution speed or gas velocity, but simply arises in the process of getting the last ounce out of the engine.

In view of the small range of difference in consumption in these part-load tests it has not been thought worth while to plot the curves showing gas velocity and consumption at the various speeds and valve areas.

The general conclusion drawn from an examination of the results shows that the fuel consumption per brake horsepower per hour is not materially affected by the use of either the largest or smallest inlet valves. In other words, it is not affected by the inlet gas velocity at any prescribed number of revolutions per minute.

The author has now briefly considered the various factors in engine performance of brake horsepower, brake mean effective pressure and fuel consumption with respect to inlet gas velocity.

The experimental evidence obtained from the tests shows that within much wider limits than are usually accepted, inlet gas velocity does not appreciably affect performance either in respect of power or consumption.

The author would emphasize the fact that the range of engine speed applying to these tests is that which is more applicable to touring car engines than to racing engines. In view of his experience with the latter he would not extend the above conclusions as to the effect, or rather non-effect, of inlet gas velocity on maximum power.

So far nothing has been said about exhaust valve effects. In all the tests on engine *B* the author is quite sure that the area of the exhaust valve was such as to produce no back pressure or exhaust choking effect. This engine had, in fact, two exhaust valves. Whether both were in use or only one made not the slightest difference in any of the experiments made on this point. Only one exhaust valve was used throughout all the experiments. With regard to engine *A* there is room for doubt as to whether the exhaust was sufficiently free with the 0.7 sq. in. valve area, but for the larger sizes of inlet valve the author is confident that the exhaust valve was adequate.

The carbureters and the induction pipes used on each engine were similar in each case, and are shown diagrammatically in Figs. 5 and 6. (*To be continued*)

Support for Highways Development

ROADBUILDING, at a standstill during the war because of lack of materials, now promises to outstrip all past records in the history of highway construction in this country. Appropriations already made and bills pending give assurance that an appreciation of the value of good roads has come out of the war, that the work of the various associations at Washington, the request of President Wilson and the activities of the Highways Transport Committee are bearing fruit.

That the manufacturers are interested in good roads goes without saying. The increased business that can result both to car and to truck makers from a network of highways is well recognized.

The National Automobile Chamber of Commerce, awake to the situation from its angle, has already established a representative at Washington to look after the highways developments. But the individual manufacturers at this time should also engage in every manner possible to further the work.

Advertisements, salesmen, agents, dealers and every agency should to a reasonable extent be used to promote the building of highways now while legislators and the public both seem completely "sold" on the value of "good roads everywhere."

Limit Tire Sizes Gradually

ONE of the governmental war restrictions important both to industry and to war was that limiting the sizes of tires, and the recent decision of the manufacturers to resume manufacture of all sizes demanded should be temporary only.

Undoubtedly many car makers would suffer heavy losses if suddenly forced to meet the manufacturing conditions created by the tire size limits. But the reduction of tire sizes from more than 200 of the pneumatic types to 9 and from more than 100 solids to 14 is too efficient a plan to be dropped entirely. It simplifies manufacture, labor and factory problems too well to be given up merely because of the temporary expense involved.

The best course would be one allowing a very gradual elimination of tire sizes and making the change less abrupt than that planned by the War Board, allowing the car makers to adopt the standard sizes as they change models, and giving the public sufficient time to consume those cars using tires that will eventually become obsolete.

Individual Truck Control Means Inefficiency

A REVERSION to pre-war methods of scattered purchase, operation and maintenance is threatened by the new Army Bill which has made no appropriation for the Motor Transport Corps and provides for the discontinuance of that body by the repeal of the Overman Act under which it was created. Appropriations as made for trucks are given to each individual division of the army.

This means that each department will again purchase the sizes and types of trucks it desires without regard to interdepartment standardization. There will no doubt again be hundreds of types in use and thousands of different parts in stock for maintenance and repair.

The present return to pre-war individualism of departments points to inefficiency of truck operation, increased costs in maintenance, and a breaking up of esprit de corps so essential in motor transport work.

The plan now considered and provided for by the bill means confusion, waste, extravagance and inefficiency. It means duplication of buying, operation and maintenance effort and lack of that single control that provides for comprehensive operation of truck convoys, repairshops and training schools.

The Army Bill must be amended to provide properly for the continuation of the Motor Transport Corps or it must in some other manner place all motor transport under one directing head.

Dirigibles for Commercial Flights

THE discussion of commercial possibilities of aircraft presupposes a careful differentiation between lighter-than-air types, such as dirigibles, and the heavier-than-air machines, such as airplanes. At present too many are inclined to think that because the airplane proved itself such a potent factor in war it will entirely dominate the field of commercial aircraft. The failure of the Zeppelins as war machines must not lead to the rejection of this type for commercial uses. The Zeppelin was a war failure owing to the inflammable gas it carried and because of the large target it offered to the attacking airplane. In peace both of these handicaps disappear, and the dirigible must be generally considered in analyzing the future of commercial aviation.

These are days when the enthusiast is apt to make hasty deductions regarding commercial aviation. The fact that the passenger airplane might cross the Atlantic should not be looked upon as more than a daredevil demonstration. Those who would immediately begin organizing a transatlantic mail service because of such a demonstration would be working an injury to the future of commercial aviation.

On the other hand, a war demonstration of Allied army dirigibles has been sufficient to point definitely to the possibilities of those craft for commercial uses. For transatlantic work, so far as conditions can be judged to-day, there is no possibility of comparison between the dirigible type and the airplane type. The dirigible looks like the practical vehicle for this ocean service, for at present there are dirigibles in existence in Great Britain and possibly in France, as well as in Germany, which could make a two-way ocean trip without the necessity of landing. These dirigibles have great carrying capacity. With such a positive form of aerial transportation now in existence, it seems foolhardy to attempt the uncommercial field of the airplane for such great distances.

In commercial aviation, as in any other industry that has to be built on some fundamentals, the mind must rule and not the heart. Perhaps crossing the Atlantic in an airplane appeals amazingly more to the imagination than crossing it in a dirigible, but from a financial point of view the other does not admit of comparison. To-day there is entirely too much enthusiasm for commercial aviation and too few analyses of what the requirements are before commercial aviation can be started.

What is the use of organizing large companies for commercial transportation by airplane without first having the necessary where-with-all with which to carry on such an organization? We cannot operate a railroad without the right of way, stations, telegraph lines, freight houses, and other physical equipment. An aerial transport system cannot be operated without a parallel set of physical requirements. To make it possible to fly an airplane from New York to Chicago there must be landing fields, and it would be utterly impossible to start a commercial line of aircraft transportation between the two cities without a completely perfected scheme of landing fields. Nobody knows definitely how far apart these landing fields should be, but the consensus of opinion of those who have made a close study of it abroad think that 10 to 15 miles is the maximum distance between landing grounds, and that there should be larger airdromes at other intervals. These students of commercial aviation are of the opinion that no plane should be flown more than 300 miles even in commercial use without landing. This finds a parallel in the short-run of the railroad locomotive which has been necessary in railroad operation.

In addition to the continuous chain of landing fields, there is other equipment necessary before a line of commercial aviation could be successful. The entire area must be properly marked with signals so that the aviator can follow the course by day or by night. This calls for some form of electric signals by night, not only on the course, but off it. Imagine the difficulty of an aerial pilot who found himself some night wide of his course due to high winds, and because of low clouds taken entirely out of contact with the course and the signals. It would mean almost certain destruction to the pilot and his load.

There is also need for a complete wireless system, not only on the planes, but on the landing fields, and also over much of the adjacent territory. This calls for a comprehensive course in aerial navigation and the pilot must be schooled in it as thoroughly as the sea captain of to-day.

Commercial aviation is confronted with other problems that must be solved before the work can be a success or even a warrantable business venture. Climatic conditions change very greatly in a distance of 250 miles, and a complete meteorological system is necessary, together with a

Latest News of the

Foreign Import Restrictions Continued and Increased

American Makers Must Overcome Serious Problems—Most Important Countries Have Restrictions

WASHINGTON, Feb. 18—That American manufacturers must seriously consider the existing restrictions and embargoes on the importation of automotive products in the important foreign countries of the world is evidenced more clearly daily as these restrictions become more severe.

A summary of the foreign import restrictions shows clearly the difficulties and obstacles of the American exporter. Few of the important countries are without some form of severe restrictions. A complete prohibition is in force in the United Kingdom. A duty of 70 per cent applies to lower priced cars in France, and import licenses which are required are only rarely granted. The unfavorable currency exchange conditions in Italy and the United States form a barrier to exports to that country. Likewise restrictions in the Scandinavian countries, the Netherlands, Switzerland, Australia, Canada and the British West Indies display the need for finding a solution to the problem. There are no American restrictions on the exports of automobiles or other automotive products.

Following is the latest available list of foreign import restrictions, together with a summary of the import and export situation as revealed by recent War Trade Board announcements:

UNITED KINGDOM

A prohibition in force in the United Kingdom against the importation of motor cars, chassis, motorcycles, and parts and accessories of motor cars and motorcycles (other than tires) is based on two orders of March 21 and June 27, 1916, both of which are still in effect. Rubber manufacturers, including tires, have been prohibited since May 10, 1917, and agricultural machinery, including tractors, since Feb. 23, 1917. It is to be observed that when licenses are granted for the importation of passenger motor cars they will be subject to a duty of 33⅓ per cent ad valorem. In determining the duty payable the value of tires is excluded.

FRANCE

Import licenses are still required for the importation of automobiles and motor trucks, motorcycles, and tractors into France and Algeria. When licenses are exceptionally granted for automobiles the special rate of 70 per cent ad valorem will apply to such vehicles when weighing less than 2500 kilos.

FRENCH COLONIES

The French prohibitions are not automatically extended to the French colonies, but the Government of Tunis is understood to have adopted prohibitions in practically the same form as in France.

ITALY

All goods imported into Italy from the United States require import licenses, and by reason of the unfavorable exchange conditions it is improbable that any modification will be made in the near future.

SCANDINAVIAN COUNTRIES

By reason of the special arrangements entered into between the Allied Governments and the United States and the Scandinavian countries, import licenses from the respective governments or government associations are required before the United States export licenses will be issued.

NETHERLANDS

All goods, including automobiles, must be consigned to the Netherlands Overseas Trust.

SWITZERLAND

Motor cars shipped to Switzerland require import licenses and must be consigned to the S. S. S.

AUSTRALIA

Automobiles are admitted into Australia only when each body is accompanied by two chassis. No prohibition is in force against the importation of motor trucks, farm tractors, or motorcycles.

CANADA

Automobiles for passenger use or susceptible of passenger use, when costing over $1,200 f.o.b. factory, are not admitted from the United States, Newfoundland, St. Pierre and Miquelon and the United Kingdom. All automobiles from other countries are prohibited. There is no prohibition on tractors, trucks, or motorcycles.

BRITISH WEST INDIES

There is stil in force a prohibition against the importation of motor vehicles in Trinidad, the Leeward and Windward Islands, and British Guiana. This prohibition applies also to bicycles, tricycles, and all classes of motor vehicles. It is doubtful, however, whether it would extend to tractors.

OTHER COUNTRIES

Practical difficulties prevent the shipment of automobiles or other motor vehicles to Finland and Russia. There are no restrictions against the importation of motor vehicles in the Union of South Africa or Egypt. The following countries have recently removed their restrictions against importation of motor vehicles: Belgium, British India, Straits Settlements, and Federated Malay States. There is no prohibition against the importation of automobiles into Ceylon, but the prohibitive duty of 100 per cent ad valorem is understood to be still in force.

The War Trade Board will grant licenses freely for the export of automotive products to all nations providing that the applications are otherwise in order. The board does not guarantee that the issuance of the licenses will permit the entry of the car into the foreign country. It advises all manufacturers to depend entirely upon their representatives in each country. The reason for this is chiefly that the restrictions of the different nations are changed so rapidly that the War Trade Board cannot follow them closely and does grant licenses freely only because automotive products are not on the conservation list.

Exports which have been prohibited to some nations during the war are gradually resuming. The War Trade Board expects shortly to announce that shipments can be made to Finland. It is probable that there will be an inter-Allied Committee at Helsingfors which will pass upon all imports from this country. American exporters who are interested in trading with Finland are advised to communicate with their correspondents there as soon as possible and request them to get in touch with the American Consul at Helsingfors. Trade can now be resumed by American exporters with Servia and Rumania. Export licenses will be necessary but will be granted freely under the same conditions as for other European countries. The board has received no official advice as to what import regulations may be in force in Serbia and Rumania and exporters are advised to communicate with their customers abroad before making shipments. Import restrictions to Belgium have been revised and have been eliminated as regards all automotive products. Applications for all import licenses should, if possible, be made by representatives of American firms in Belgium. Restrictions against the importation of rubber tires into Norway, Sweden, Holland, and Denmark have been lifted and licenses will now be granted freely, subject only to the condition that the proper import certificates have been issued.

Allotments of shipping space have been made by the Shipping Board for the East Coast of South American trade, which will be sufficient to take care of all of the cargo offered in the immediate future for these markets. For this reason the shipping preference procedure and priority system will no longer be necessary and manufacturers of automotive products, it is expected, will find ample space for their exports to the Southern continent.

Sub-Contractors Holding Up Contract Settlements

DETROIT, Feb. 18—Sub-contractors of war material are not making proper efforts to secure the settlement of their claims, declares J. J. Crowley, president of the Michigan section, National Association of Manufacturers of War Materials. Figures received from Washington show that the Ordnance District Board in Detroit has 276 contracts to settle, of which only 82 have been presented to the board by the contractors. Contractors declare they are delayed because their sub-contractors are negligent in making speedy returns. Of the 82 claims presented, 12 have been allowed.

Automotive Industries

France Prohibits Auto Imports

Embargo Against Automobile Imports for One Year—Importers Object

By W. F. Bradley

PARIS, Feb. 6—The importation of automobiles into France has been forbidden for about one year. Previous to this, motor vehicles were only admitted on payment of a 70 per cent duty. French automobile manufacturers, as a class, are satisfied with the present conditions, for, as they have not yet returned their factories completely to peace conditions, the prohibition of imports removes all foreign competition.

Importers, and particularly those who were established in France before the war, are very dissatisfied. At the present time there is a strong demand for all kinds of automobiles, and, as the home manufacturers cannot possibly meet this demand, the general public would not be displeased to see foreign cars brought in. The most important phase of this situation is what attitude France will adopt with regard to the importation of foreign cars. If, as many of the manufacturers request, the 70 per cent duty is maintained for a long period, very few, if any, foreign automobiles can be sold in France.

Although the cry for a 70 per cent duty is still strong, it is not heard as persistently as was the case a few months ago; probably makers are beginning to realize that they cannot erect a high tariff wall to protect themselves without other nations doing likewise. As France, before the war, was the greatest motor exporting nation in the world, and as her productive ability has enormously increased during the war, it is important that she should find outlets in foreign markets; it is hardly likely that she will get this free outlet if she protects her own market with a practically prohibitive import duty. Only one French manufacturer of any importance has loudly denounced the folly of the 70 per cent proposition. This is André Citroen, who has only recently entered the automobile industry and who, during the last few days, has issued all particulars regarding his program.

The man responsible for the present prohibition of automobile imports is M. Loucheur, Minister of Reconstruction. It is well known that pressure from all quarters has been brought to bear, but the ministry, of which M. Loucheur is the head, has persistently refused to admit any change.

The negotiations between automobile importers and the French Government were of a private nature until to-day, when, breaking away from the previous line of action, the Ford Motor Co. of France has come out with a half-page advertisement in the *New York Herald* in which the whole situation is explained in detail. The Ford Motor Co. shows that not only has M. Loucheur persistently refused to allow any foreign automobiles to be brought into France, but at the present time he will not allow Ford automobiles lying idle at the docks to go into service despite the very urgent need for supplementary transportation.

It appears that the Tardieu Commission purchased about 8500 Ford automobiles at a cost of approximately $375 each, delivery for export at American ports. About 4500 of these automobiles are new and have never seen service; they comprise 3500 that have not yet been delivered from the Ford company's works at Bordeaux, and 1000 which have been delivered and until recently were lying in automobile parks at Bordeaux and Versailles. The Ford company suggests that the French Government should release or sell back to them these 4500 cars at the price paid by the Government, plus a payment of $38, which payment could be considered either as profit or to cover cost of ocean transportation.

The Ford company proposes to sell these cars in France to customers who are in immediate and urgent need of them, such as doctors, veterinary surgeons, commercial firms, etc. In addition to paying for the automobiles at the cost and plus the profit before said, the Ford company also proposes to pay 70 per cent ad valorem duty on the above price of $375 and the purchaser would also pay 10 per cent luxury tax on the retail selling price of the vehicles. The selling price would be $1,300. It may be mentioned that this price is very high for a Ford car, but there is no doubt that the 4500 automobiles could be disposed of in France immediately on these conditions.

The Ford company points out that the following advantages would accrue to the French Government by accepting their proposal:

1—Immediate cessation of the cost of maintenance, housing, etc., 4500 cars.

2—Complete immunity from any possible loss in respect thereof.

3—Resumption on the basis of established law of commercial business amounting to a total turnover exceeding 32 million francs.

4—Receipt by the French Government of custom duty and luxury tax amounting to 8,831,250 francs.

5—Receipt by the French Government

To Make All Sizes of Tires

Makers to Abolish War Tire Limits—All Sizes Demanded to Be Made

NEW YORK, Feb. 19—The limits set on the manufacture of tires by the War Industries Board during the war will not be followed in the future, and all sizes of tires demanded by the public will be manufactured, according to an announcement by the National Automobile Chamber of Commerce, made public today.

This decision followed a meeting of tire and automobile makers in Detroit late last week. The restrictions placed on tire manufacture by the War Industries Board in an effort to conserve rubber, labor and factory facilities in the spring of 1918 called for a reduction of pneumatic tires from a range of 200 sizes and types to nine sizes and types, the reduction to be made over a period of two years. Truck tires were reduced by a similar order from over 100 types and sizes to fourteen, affecting chiefly those tires used on 1- and 2-ton trucks.

The representatives of the N. A. C. C. and the tire industry, present, agreed also that for the time being it will be most wise to continue export of tires in metric sizes only, as has been the custom. This question of shipping tires abroad marked similarly to those used in this country for domestic consumption is to come again in the near future when members of the tire industry will confer with J. Walter Drake, chairman of the tire committee of the N. A. C. C.

The decision to manufacture all sizes of tires regardless of the War Industries Board rules followed the discovery that 2,000,000 32 x 4 tires, for example, were needed with 1,000,000 for equipment of 200,000 cars in process of manufacture and 1,000,000 for maintenance. This was one of the sizes that were to be abolished. Similarly other sizes were found necessary; hence the decision to make all sizes demanded.

Hanch Sails for Europe

NEW YORK, Feb. 17—C. C. Hanch, formerly chief of the Automotive Section, War Industries Board, sailed today for Paris, where he will attend the Inter-Allied Council of Automobile Manufacturers meeting on March 5 as the representative of the National Automobile Chamber of Commerce. He will also investigate industrial and trade conditions.

Nation Awakens to Worth of Good Roads

States Appropriate Millions for Highways—Nation-Wide Acceptance of Need for Improved Roads—$200,000,000 Available for That Purpose This Year

WASHINGTON, Feb. 17—A nation-wide ambition for a complete network of good roads and highways through the country is evidenced by reports received here of State appropriations for highways, and by the popular approval that has been expressed in favor of the National Highway bills now before Congress.

It appears that, as a result of the work of the various associations, the expression of President Wilson in favor of good roads, and the activities of the Highways Transport Committee during the war, the plan for good roads has suddenly become crystallized in the minds of the entire country.

$200,000,000 Available

Reports received here indicate that all of the States are considering road appropriations, and several have already passed the necessary bills for funds covering the next few years.

Minnesota has appropriated $100,000,000, South Carolina, $40,000,000; Illinois, $60.000,000; Pennsylvania, $50,000,000; Georgia, $40,000,000; Colorado, $20,000,000, and Alabama, $10,000,000, to be used in conjunction with the funds appropriated by the 1917 Federal Road act for the development of the highways.

It is estimated that between $200,000,000 and $300,000,000 will be available for highways during 1919. The Federal Road act appropriated $5,000,000 in 1916-17, $10,000,000 in 1917-18, $15,000,000 in 1918-19, a total of $30,000,000, of which $1,487,336 has been actually paid out by the Treasury, and a total of $10,303,379 has been set aside.

827 Road Construction Projects

Eight hundred twenty-seven projects for road construction have been submitted to date, of which 760 were approved at an expenditure of $21,112,795.30 of Federal funds and $35,069,051.42 of State funds, a total of $56,171,846.72. These funds are for projects covering 7869 miles. The money actually expended to date was for ten projects of forty-four miles, which have been completed. The reason for the delay in completion of highways and for the small amount actually expended is the war, during which it was impossible to use freight cars or secure materials for highway construction.

The new Bankhead bill, which will probably be passed by Congress, and which has already been passed by the Senate, provides for $200,000,000, with $50.000 000 available at once for 1918-19, $75,000,000 in 1919-20 and $75,000,000 in 1920-21, This bill, which has been described in these columns before, is practically an amendment and continuation of the original Federal Road act of 1916. The States must provide appropriations on a dollar for dollar basis to secure their share of the National funds.

In consequence of the Bankhead bill and funds already available, there will be at least $200,000,000 to be expended in 1919 if the States comply immediately with the conditions of the Federal Road act and provide the dollar for dollar State funds.

Of the $30,000,000 originally appropriated by the Federal Road act, $20,000,000 are still available, and in addition there are $35,000,000 appropriated by States which are still available, making a total of $65,000,000.

Fifty million dollars are appropriated by the Bankhead bill for 1919, and an additional $50,000,000 will be voted by the various States, making a total of $100,000,000. Consequently there will be 165 000 000 available in 1919, and as the States usually exceed the dollar for dollar basis by 50 per cent, it is probable that the total sum available will be over $200,000,000.

The National Highways Commission bill, which was the result of the Highways Association meeting in Chicago, is to be rewritten to meet the legal requirements. This bill may be presented at this session of Congress or may be held over until the next session, depending upon the opportunities presented. It is quite certain that, even though presented at this session, it will not be considered until some future date.

Other Government departments besides the Department of Agriculture are also displaying an interest in road construction. The Department of Labor is seriously considering it as a means of employment for soldiers returning from the army camps, and is planning a slogan campaign in conjunction with the American Federation of Labor. The slogans will be advertised throughout the country intensively so that they reach every community and home.

Good Road Slogans Prepared by Department of Labor

"Build now the National, State and County Roads we need, and Prosperity will ride to every American's gate.

"Build Now Good Roads where they are needed, so that Good Times can come to every American's home without delay.

"Build Now—Money spent wisely for Good Roads will come back because the roads will bring it back.

"Build Now Good Roads and see how quickly Good Times will roll down these roads.

"Build Now—You can Notice the earmarks of Prosperity along Good Roads."—W. B. WILSON, Secretary of Labor.

N. A. C. C. Roads Committee Secretary at Washington

WASHINGTON, Feb. 17—Pyke Johnson, a former newspaper man of Denver, Col., has been made the secretary of the Roads Committee of the National Automobile Chamber of Commerce, with headquarters at the Washington office of the National Automobile Chamber of Commerce. He will compile road data and watch the development of highway legislation.

Michigan Launches Campaign for Road Amendment

LANSING, Feb. 18—A campaign to insure passage of the $50,000,000 good roads amendment, which has passed both Houses of the Legislature and will come before the voters at the April election, has been launched by the Michigan Association of Road Commissioners and Engineers. In connection with automobile clubs and good road associations throughout the State, they will conduct an intensive campaign to reach every man and woman elector with circulars and speakers.

106,930 Army Trucks in 1918

WASHINGTON, Feb. 17—One hundred and six thousand, nine hundred and thirty trucks and passenger cars were completed for the United States Army in 1918, according to a report issued by the War Department. Of this number, 89,277 were trucks, ranging from ½- to 5-ton, and 17,653 were passenger cars. Total probable production for military use for 1919 will include 28,694 trucks and passenger cars, of which 28,679 will be trucks and fifteen passenger cars.

Following is the total production for 1918, and the probable production for 1919, in sizes:

	Trucks and Passenger Cars Completed During Year 1918 for the War Department	Probable Production for 1919 for War Department
½ ton trucks....	3,454	0
¾ ton trucks....	7,260	0
¾-1 ton trucks..	2,474	0
1 ton trucks.....	16.363	6,805
1½ ton trucks...	3,095	2.268
1½ to 2 ton tr'ks	8,977	1,385
2 ton trucks.....	14.415	3.369
3 ton trucks.....	28,073	12,627
3½ ton trucks...	672	961
4 ton trucks.....	1,888	362
5 ton trucks.....	2,465	468
5½ ton trucks...	3.141	434
Passenger cars..	17,653	15
Total..........	106,930	28,694

Atterbury Capital Doubled

BUFFALO, Feb. 15—The Atterbury Motor Car Co. has increased its capital from $250,000 to $500,000 to increase production facilities.

DePalma Smashes Speed Records

Sets New Pace for 1 to 20-Mile Straightaways in Packard with Aviation Engine

DAYTONA BEACH, FLA., Feb. 18—Ralph DePalma broke all previous records for speed for distances from one to twenty miles, including those made by Burman in 1911 over the same course. Driving a Packard, equipped with a 12-cylinder, 4 x 6 aviation engine, he made his record in all instances, except that one-mile stand start, with flying starts. The engine used has a piston displacement of 904.8 cu. ft. The car was equipped with but one seat. Fuel used was gasoline seventy-nine Baume.

On Feb. 12 DePalma made a 1-mile and 1 kilometer record. On Feb. 16 and 17 he hung up records for all distances up to 20 miles, including a 1-mile standing start, formerly held by Barney Oldfield. All of these figures have been certified by the contest board of the A. A. A.

DePalma completely re-equipped his car in New York with Lynite pistons, Hartford absorbers, Goodyear tires, Willard battery and Boyce motometer.

DePalma's new records compared with former records follow:

De Palma's New Records				Old Records			
Date	Distance	Time	M. P. H.	Date	Time	M. P. H.	Driver and Car
Feb. 12, 1919	1 mile	24.02 sec.	149.8	1911	25.40 sec.	141.7	Burman, Benz
Feb. 12, 1919	1 kilometer	14.86 sec.	140.9	1911	15.88 sec.	140.8	Burman, Benz
Feb. 17, 1919	*1 mile	38.83 sec.	92.7	1910	40 53 sec.	88.8	Oldfield, Benz
Feb. 16, 1919	2 miles	49.54 sec.	145.3	1911	51.28 sec.	140.4	Burman, Benz
Feb. 16, 1919	3 miles	1:15.04 min.	143.9	....	....	....	....
Feb. 16, 1919	4 miles	1:39.77 min.	144.2	....	....	....	....
Feb. 16, 1919	5 miles	2:04.58 min.	144.2	1906	2:34 min.	116.8	Hemery, Darracq
Feb. 16, 1919	10 miles	4:09 30 min.	144.3	1909	5:14.40 min.	114.5	Bruce-Brown, Benz
Feb. 17, 1919	15 miles	6:48.55 min.	132.1	1906	10 min.	90	Lancia, Fiat
Feb. 17, 1919	20 miles	8:54.20 min.	134.7	1911	13:11.92 min.	90.9	Burman, Buick

*Standing start.

Grand Rapids Show This Week

GRAND RAPIDS, Feb. 17—The 1919 show of the Grand Rapids Automobile Business Association is being held this week, having opened to-day. It is being staged in the Klingman Building. There are fewer dealers listed in the list of exhibitors, but in spite of this more cars and trucks are on display than ever before.

Des Moines Tenth Annual Show Opens

DES MOINES, Feb. 18—The tenth annual motor show opened to-day at the local plant of the Ford Motor Co., which affords four times as much space as has been available in previous years when the show was held in the Coliseum. Iowa is flocking to the show, and as a result of last year's bumper crops is better than ever able to buy automobile goods. Sixty-four exhibitors hold space. Over 200 different models representing forty-eight makes of cars are included in the exhibit, which is the largest ever held in Iowa. Trucks and tractors are a new feature. There are thirty-five makes of trucks on display and eighteen makes of tractors.

Dayton Automobile Show March 3

DAYTON, Feb. 17—Dayton will hold its annual automobile show March 3-9. Plans for the big event are about complete. Every type of car will be exhibited at the show as well as a complete line of accessories and equipment. As airplanes and tanks are made in Dayton an effort is being made to secure one of each for the show. The exhibition hall, building No. 21 of the National Cash Register plant, provides 80,000 ft. of floor space and is 540 ft. in length. It is expected that $500,000 worth of automobiles and accessories will be on exhibition.

Shipping Board Aids Lyons Fair Exhibitors

WASHINGTON, Feb. 18—The United States Shipping Board has arranged to provide shipping space for all American exhibitors at the fourth annual Lyons Sample Fair to be held from March 1-15. The fair, endorsed by the Departments of State and Commerce, is under the patronage of the President of France. The first fair was held in 1916 with 1324 exhibitors. In 1917 there were 2593 and in 1918 3182 exhibitors. The first year's business totalled $19,000,000, while at the third fair it amounted to $150,000,000. There were 527 American exhibitors at the third fair.

The Railroad Administration will also aid exhibitors insofar as is necessary to insure quick delivery of samples to the seaboard. The charges for space at the exhibit are $110 per 20 sq. yd. Passports will be granted freely by the Department of State to all bona fide exhibitors and representatives.

Toronto Show in March

TORONTO, Feb. 17—The Ontario Automobile and Accessories Branch of the Retail Merchants' Association will hold its second annual convention on March 6-7, in Toronto. The meetings will be held in Foresters' Hall, and an exhibit of accessories and tires will be held in the basement.

General Tire & Rubber Co. Expands

AKRON, Feb. 18—The General Tire & Rubber Co. has increased its capitalization from $1,000,000 to $2,500,000.

Chandler Officials in New Company

Cleveland Automobile Co. Will Produce Low-Price Car—Production by August

CLEVELAND, Feb. 17—Officials of the Chandler Motor Car Co., this city, are interested in a new organization to build a low priced car. The new concern will be known as the Cleveland Automobile Co. and the car as the Cleveland. The company is incorporated under the laws of Delaware, with an authorized capital stock of $1,400,000. F. B. Chandler, president, and Samuel Regar, treasurer of the Chandler company, and Hornblower & Weeks New York bankers, are the leaders of the organization of the new concern, which will be identified very closely in personnel with the Chandler company. The car will be manufactured in an entirely separate factory, however, and it is expected that building will commence within 10 days on the new plant. It is proposed to be in production during the early part of the coming summer. Officials of the Cleveland company state that they have not been able to determine exactly on the price at which the new car will sell, this depending upon factory costs after getting into production. It is stated, however, that the price will be materially lower than the Chandler. It is very probable that the new product will be marketed largely through the present Chandler distributer organization.

Inventory of Army Vehicles

WASHINGTON, Feb. 15—The Motor Transport Corps is engaged in taking an inventory of every motor vehicle owned by the army and all equipment, including spare parts, machine shop parts and accessories.

Many motor vehicles had not been taken over formally by the Motor Transport Corps, having been bought and operated by the Ordnance, Quartermaster, Medical, Signal and other branches of the army, and inventories never were made.

S. A. E. Tractor Dinner Feb. 27

NEW YORK, Feb. 18—A tractor dinner will be held at the Hotel Baltimore, Kansas City, by the Society of Automotive Engineers on Thursday, Feb. 27, during the tractor show. There will be a professional session at the auditorium of the Sweeney Automobile School Thursday afternoon, when a paper on "Tractor Testing" by Prof. J. B. Davidson of the University of California and other papers on tractor engineering will be presented. Dr. Joseph E. Pogue of the U. S. Fuel Administration will discuss the fuel situation as it applies to the tractor industry, and E. R. Hewitt, consulting engineer, International Motors Co., will present a paper on the "Wheeled Farm Tractor."

Refinery Production for Eleven Months

Stocks of Gasoline and Kerosene Are Relatively Low, but Output Is Maintained

PRODUCTION

	November, 1918	October, 1918
Crude oil (bbl.)	27,411,636	29,237,767
Gasoline (gal.)	312,968,640	314,251,318

	—Stocks on Hand— Nov. 30, 1918	Oct. 31, 1918
Crude oil (bbl)	15,222,401	15,438,756
Oils purchased to be re-run (bbl.)	1,373,740	1,308,744
Gasoline (gal.)	270,072,011	250,328,329
Kerosene (gal.)	397,804,012	419,409,944
Gas and fuel (gal.)	583,777,918	596,116,351
Lubricating (gal.)	132,923,478	135,196,542
Wax (lb.)	190,953,158	195,797,590
Coke (ton)	22,005	23,905
Asphaltum (ton)	74,955	74,159
Miscellaneous (gal.)	466,887,345	457,222,127

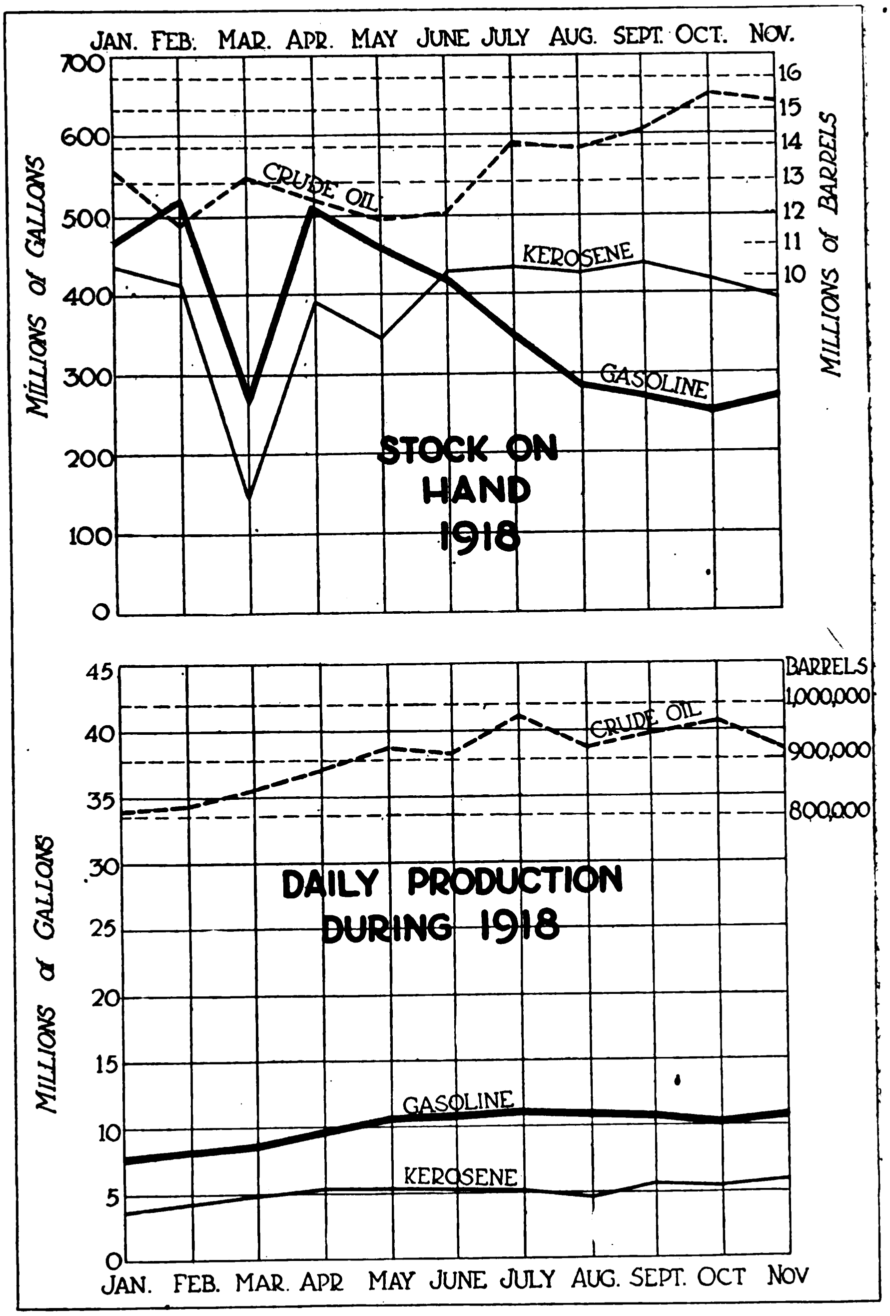
NEW YORK, Feb. 17—It is satisfactory to observe that our average daily production of gasoline, kerosene and crude oil increased steadily month by month from January to November, 1918; our total refinery output for this period also indicates that every effort is being made to produce sufficient petroleum products to keep pace with the ever-increasing demand. On the other hand, our stocks of gasoline and kerosene as of Nov. 30, 1918, are not altogether satisfactory, although in the case of the former we were on that date in a better position than in September and October. Production of crude oil is fully maintained.

At the present time it does not seem likely that our gasoline stocks will show (when figures are available) well in comparison with stocks held in January and February last. The winter has, so far, been abnormally favorable for motoring, and it may be assumed that gasoline consumption has been greater than usual. Against this is the fact that our average daily production of gasoline in January, 1918, was but 7,826,840 gal., as against 10,432,288 gal. per day average in November.

A probable decrease in the quantity of special gasoline for aircraft use may be anticipated, a circumstance which will have its effect on the general supply. During wartime our exports of aircraft gasoline have been very large, and our domestic needs have been extensive.

Our production of gas and fuel oil continues to be maintained. Much of this has been used for war purposes, and although its use in this direction may be curtailed with the coming of peace, there are a great number of oil-burning merchant vessels operating and being built, and doubtless the demand will continue. In a general way, the production of gas and fuel oil means increased production, as every trace of gasoline must be extracted from fuel oil before it is suitable for the purpose for which it is intended.

Petroleum Products Stock and Production for 1918



These charts show how we stood as regards stock and average daily production of crude oil, gasoline and kerosene during eleven months of 1918

Stutz Profits Drop

INDIANAPOLIS, Feb. 17—The Stutz Motor Car Co. of America, Inc., for the year ended Dec. 31, 1918, shows net profits of $594,047 as against $1,074,778 for 1917, a decrease of $484,731 for the past year. Gross profits decreased $462,615, from $1,107,334 in 1917 to $644,719 in 1918, and net sales decreased $946,758, a drop from $4,483,315 in 1917 to $3,536,557 in 1918. The complete balance sheet for the past three years follows:

Assets	1918	1917	1916
Plant, equipment, etc.	$2,675,854	$2,560,731	$2,431,603
Cash	167,118	252,811	74,059
Accounts Receivable	225,435	58,816	145,530
Inventory	804,857	1,148,470	577,248
Liberty Bonds	50,000	......	......
Total	$3,923,264	$4,015,829	$3,228,441

Liabilities			
Capital stock	$375,000	$375,000	$375,000
Accounts payable	358,257	317,462	356,980
Deposits on cars	30,500	35,450	17,700
Liberty bonds	12,500	......	......
Taxes, etc.	10,579	6,000	8,500
Reserves	87,162	59,491	31,329
Surplus, after payment of Federal taxes, dividends, etc.	3,049,266	3,222,425	2,439,021
Total	$3,923,264	$4,015,829	$3,228,441

—

Wheat Instead of Hession Tractor

BUFFALO, Feb. 18—The Wheat tractor is the new name for the Hession Tiller & Tractor Corp.'s four-wheel farm and road tractor, formerly known as Hession.

Post Office Department Has 1200 Army Trucks

WASHINGTON, Feb. 19—The War Department has turned over 1200 army trucks of various types and sizes to the Post Office Department for use in rural mail delivery. Announcement will be made in the near future by the post office of the routes covered by these vehicles. The trucks are turned over by the War Department in compliance with a provision in the Army Appropriation bill of 1918 which ordered all trucks delivered to the Post Office as are requisitioned.

—

Nash Pays Extra Dividend

KENOSHA, Feb. 15—In addition to the regular 7 per cent dividend on preferred, Nash Motors Co. has declared a total of $21 per share on common. An initial dividend of $6 per share on common was paid Feb. 1, and another common dividend of $10 per share is payable Feb. 15.

The Nash business for 1918 amounted to $41,000,000. This represents the production of about 21,000 cars and trucks. It is planned for 1919 to build 25,000 cars and as many trucks as conditions warrant.

—

Studebaker Dividends

Studebaker Corp., South Bend, 1 per cent, common; 1¾ per cent, preferred; payable March 1 to stockholders of record Feb. 20.

—

Hammered Piston Rings Bought by Bartlett Hayward Co.

BALTIMORE, Feb. 14—The Bartlett Hayward Co. has purchased the entire capital stock of the Hammered Piston Ring Co. of America, whose plant is located on South Eleventh Street, Newark. It contemplates keeping the Newark plant in operation, but all increases of business will be handled in one of its plants in Baltimore. The active management of the business will remain in charge of C. F. Hockley, vice-president and general manager, who will make headquarters in Newark.

—

Ricardo Engine "Made Good" in Tanks

(*Continued from page* 410)

safely be used, thus insuring silent running.

(4) Since the crosshead and guide can be profusely lubricated with clean oil, the wear is reduced to a minimum. Further, both the crosshead sleeve and its guide are small and inexpensive parts, which could in the event of wear be replaced at a very small outlay.

(5) Since the piston itself does not bear upon the cylinder walls, an ample working clearance can be allowed without any risk of noise.

(6) The wear on the cylinder walls is reduced to a minimum, since only the piston rings bear against them and there is no side thrust.

(7) The gudgeon pin being short, stiff and free to rotate, and also being placed in such a position that it receives very little heat from the piston, does not wear perceptibly. The combined wear of the gudgeon pin and bushes after a test run of 450 hours on a large six-cylinder engine at full speed, and an average of nine-tenths full power, was officially reported as being "not measurable" in any of the six pistons.

(8) The heat from the crown of the piston and from the crosshead guide is utilized to warm the air for the carbureter, and is not transferred to the crankcase.

(9) All the working parts can be lubricated without stint and without any risk of excess of oil reaching the cylinder walls; also the oil remains clean.

(10) In the event of any fuel condensing on the walls of the cylinder its subsequent passage into the crankcase can be prevented absolutely.

(11) The restricted lubrication to the cylinder walls prevents any tendency of the piston rings to become carbonized or gummed up. In practice the piston rings always remain clean and perfectly free.

(12) There is no tendency for the engine to become gummed up when cold, and it is in fact almost as free when cold as when hot, and consequently is always very easy to start.

An engine with this piston will be somewhat higher than a conventional engine, somewhat heavier and slightly more expensive to manufacture. The design should recommend itself particularly to engineers aiming at a high fuel economy or those desiring to use heavier grades of fuel, such as kerosene.

Bill Taxing Cars and Trucks Passed by Senate

WASHINGTON, Feb. 14—The new revenue bill, carrying among its provisions a tax of 5 per cent on automobiles and parts, and 3 per cent on trucks and parts, was passed by the Senate yesterday. It now goes to the President for his approval. The bill contains the provisions relative to automotive products just as they were published in AUTOMOTIVE INDUSTRIES last week.

—

Ohio Plans to Spend Millions on Roads

COLUMBUS, Feb. 18—The federal government and the state jointly will spend $15,000,000 annually during the next five years for the improvement of roads through the Buckeye State if a resolution just introduced in the house is adopted and government authorities concur. Congress is requested to appropriate $1,000,000,000 for good roads, the money to be spent during the next five years.

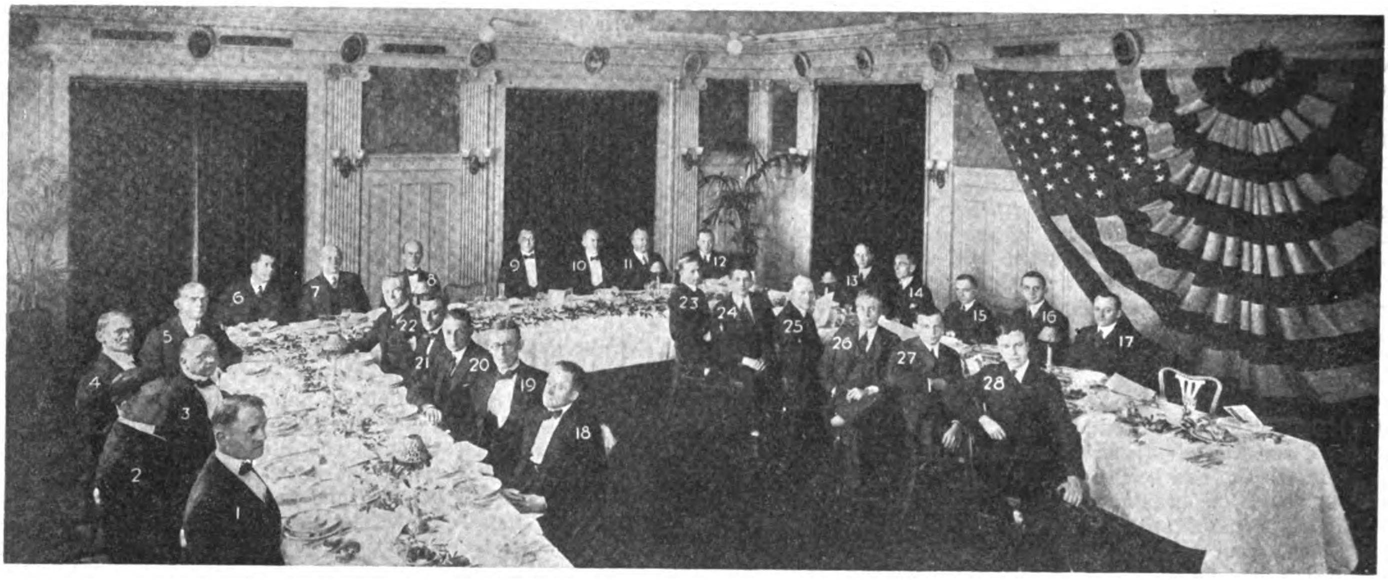
Dinner of Automotive Electric Association, Hotel Astor, Feb. 11, 1919



1—E. E. Turner, Assistant Secretary.
2—G. H. Lewis, Westinghouse Electric & Mfg. Co.
3—S. L. Nicholson, Westinghouse Electric & Mfg. Co.
4—E. S. Philips, Philips-Brinton Co.
5—V. S. Beam, Westinghouse Electric & Mfg. Co.
6—B. M. Leece, Leece-Neville Co.
7—J. K. Montgomery, North-East Electric Co.
8—O. L. Harrison, Dayton Eng. Lab. Co.
9—G. B. Griffin, Westinghouse Electric & Mfg. Co.
10—J. J. Jackson, Westinghouse Electric & Mfg. Co.
11—R. W. Sutherland, Splitdorf Electric Co.
12—G. S. Cole, Leece-Neville Co.
13—A. F. Kurs, Leece-Neville Co.
14—A. L. Howland, Electric Auto-Lite Corp.
15—H. C. Branch, Leece-Neville Co.
16—O. F. Conklin, Remy Elec. Co.
17—A. H. Timmerman, Wagner Electric Mfg. Co.
18—J. C. McQuiston, Westinghouse Electric & Mfg. Co.
19—W. A. Chryst, Dayton Eng. Lab. Co.
20—J. G. Greenleaf, Gray & Davis.
21—W. B. Moses, Gray & Davis.
22—W. Gray, Gray & Davis.
23—J. M. Noble, Prest-O-Lite Co.
24—J. C. Halbleib, North-East Electric Co.
25—R. J. Nightingale, Willard Storage Battery Co.
26—T. R. Cook, Willard Storage Battery Co.
27—F. F. Dorsey, North-East Electric Co.
28—O. W. A. Oetting, Willard Storage Battery Co.

British Guiana a Market for Tractors

WASHINGTON, Feb. 14—A good market for farm tractors exists in British Guiana, according to a consular report from that country, which states that the use of tractors there has been highly satisfactory. An increased use of automobiles is also apparent, 236 having been imported in 1917 as compared with 147 in 1916.

The country has been exceedingly prosperous. Its leading industries, sugar, rice and balata, have been in great demand. Little difficulty has been experienced in financing trade, although rates of exchange were above normal.

Truck Show Called Success

NEW YORK, Feb. 17—From an advertising and prospect-gathering point of view, the exclusive commercial vehicle show staged as part two of the two-week exhibition put on in Madison Square Garden and the Sixty-ninth Regiment Armory by the New York dealers can be written down as a success. And, although the dealers did not expect to close very much actual business at the show, exhibitors report that sales have been up to expectations.

The advertising value of the show has been great, and, in the opinion of dealers, great advertising is necessary. They will have to sell this year as many trucks as were produced in the years 1916 and 1915 combined. The feeling at present is optimistic. Businesses are expanding and everywhere the call for transportation is insistent. And a big part of the success of the show will come from placing before business multitudes of sizes and varieties of individual and special transportation represented by the motor truck.

Attendance is said to have been satisfactory. At no time were the two halls over-crowded, but it was a business crowd that passed the ticket takers.

Those who exhibited tractors proclaim themselves more than satisfied with results. One firm closed wholesale territory for Maine, Vermont, Massachusetts, Connecticut and the British West Indies. Another filled a book with prospects' names and expects to close a good percentage of them.

Exports Control Committee to Dissolve

WASHINGTON, Feb. 14—Dissolution of the Exports Control Committee as early as March 1 is suggested by the chairman of that committee in a letter addressed to Secretary of War Newton D. Baker and Secretary of the Navy Daniels. This committee had control of export shipments during the war by routing, allocation and other necessary restrictions. Its plan to dissolve in the near future forecasts a complete return to normal shipping conditions.

May Ship Tires Without Special License

WASHINGTON, Feb. 14—In shipping automobiles to Denmark, Norway, Sweden and Holland, it will no longer be necessary, according to the War Trade Board, to furnish with the application for export licenses an import certificate number covering the tires on the automobile. The import certificate for an automobile, and an export license issued therefor, will include the necessary tires.

Australia-London Air Route Planned

WASHINGTON, Feb. 18—An aerial service is planned between Australia and London by private Australian business men who have formed a company under Reginald Lloyd of London with a paid-up capital of $48,665.

The purpose of the company is to explore the proposed route for landing sites, to be approximately 300 miles apart. The route is to be from Sydney or Melbourne direct to Port Darwin, in the northern territory of Australia, from which point there will be a 300-mile sea trip across to the Island of Timor in the Dutch East Indies, thence from island to island through Java and Sumatra to Singapore and Calcutta, across India to Karachi, thence to Bagdad and Port Said, from which latter point the choice of several developed aerial routes to London are available.

Next month Mr. Lloyd will lead a surveying party from Australia through the Dutch East Indies, the Malay States, India and Mesopotamia, to locate landing sites and to arrange for their lease or purchase. The organization of the present company is merely to provide for the expenses of this routing party. After the completion of this survey it is proposed to finance a company in London to operate the aerial service to Australia.

Value of War Vehicles

WASHINGTON, Feb. 15—According to a report made public to-day by the War Department, there were motor vehicles valued at $69,567,173 on hand on Nov. 1, 1918, and $79,908,070 on Jan. 1, 1919.

Air Medical Tests for Flyers

But 61 Per Cent Qualify for All Duties—Trained to Flying Experiences on Ground

WASHINGTON, Feb. 18—Of each 100 flyers accepted by the medical service of the Aviation Corps, 61 are capable of flying in altitudes over 28,000 ft., 25 are capable of flying in altitudes up to 15,000 ft. and 14 are capable of flying at 8000 ft. or less. Consequently, 61 are fitted for any air work, 25 may perform such work as bombing and 14 are limited to night bombing. These figures are the results of numerous tests made by the Air Medical Service, following the acceptance of candidates for flying duties.

The tests for altitude are made on the ground by means of a device called the "Flack-bag," which reduces the oxygen the aviator breathes so that within 25 minutes there is but 8 per cent of oxygen in the tank, creating an atmosphere equal to 28,000 ft. The weaker flyers taking this test quickly react to the limited supply of oxygen.

Other tests are also made for vision and balancing, both of which are affected by altitude. Low oxygen effects the vision. The tests given are also used to determine which men have better "night sight" for night bombing work.

Performance of stunts and low oxygen affect the internal ear, and cause the flier to lose his balance. Consequently, examinations were made of the internal ear to determine whether or not flyers are capable of withstanding low oxygen and whether they are able to perform stunts without losing their sense of balance.

All flyers are frequently examined by a re-breathing test, as it has been found that in many instances men who are capable of standing 25,000 ft. altitude at one time, are not equal to it at other periods.

In making the tests for examination of stunting ability, flyers are placed in a machine called the "Ruggles Orientator." This machine allows the cadet to acquire flying experience without leaving the ground.

It is a modification of the old-fashioned universal joint, composed of three concentric rings so pivoted together as to permit the fuselage, which is pivoted within the innermost ring through every possible evolution to be experienced in actual flying. It is practically an airplane in every respect. The cadet sits in the fuselage and by means of control stick and rudder puts himself through all the evolutions he is later to experience in the air. These evolutions stimulate the internal ear, which send the nerve impulses to the brain. Consequently, after flying day after day in this apparatus the cadet is entirely familiar with the sensations he will experience in an air flight. He is thus prepared to realize and cope with the peculiar conditions incidental to aviation.

The Air Medical Service divides its system of operation in three ways: Selection, classification and maintenance. Tests for selection are standardized. Examiners making the tests are also standardized.

A late innovation in the Air Medical Service includes what is known as the Flight Surgeon, who examines intimately the conditions in aviation accidents, and makes recommendations accordingly. For example: He finds that the cowl of an airplane provides too little play for the head, and that flyers cut their heads in crashes as a result. He recommends more room. Such recommendations have been shown to result in 10 to 30 per cent less accidents. Another recommendation instituted the use of a rubber shock absorber, used to attach the safety belt to the machine. This lessened the number of broken ribs.

Dealers Hold Tractor Agencies

No Thought of Giving Up Truck or Tractor Agencies—Minneapolis Show Huge Success

MINNEAPOLIS, Feb. 19—The rumors that dealers will give up truck and tractor agencies and handle passenger cars only in these post-war days are entirely unfounded as far as this section is concerned. Interviews with many dealers at the 1919 Northwestern Automotive and Industrial Exposition here shows them very enthusiastic over the passenger car outlook, but in no way inclined to give up truck or tractor business.

The show is a huge success. Attendance records are far in excess of all previous years. Good crops and high prices for them have resulted in a good prosperity. Farmers and dealers are here from the entire territory solely for the show.

Highway Committee's Report to Annual Convention

NEW YORK, Feb. 20—The National Highway Committee of the American Road Builders' Association has prepared an interesting report on the problem of adequate roads for presentation at the ninth annual convention. This convention will be held at the Hotel McAlpin, Feb. 25-28.

In this report reference is made to the new era of highway transportation and the necessity of providing adequately for the traffic, maintaining the road systems and connecting the interior with the seaboard in such a way as to obtain maximum results. The benefits to be derived from the establishment of a national highway system, built and maintained by the Federal Government, are also dealt with in detail. The matter of military benefit resulting from such a system is also considered. It is expected that this report will be presented at the Feb. 27th session of the convention.

Labor Standards of England Changed

Shorter Working Hours More Productive—Workers Use Spare Time Profitably

LONDON, Feb. 1—The majority of factories in Great Britain went on a 47-hr. week schedule on Jan. 1, as compared with 52- and 56-hr. formerly. During the war many of the companies worked from 6 a. m. until 6.30 p. m. There has been a good deal of opposition on the part of many British manufacturers to the 47-hr. week on the ground that the laborer would scarcely know what to do with his extra time. There was a general feeling that he would spend his time and money at the saloon, so the shorter working hour would be an evil rather than a benefit.

The case of the Ford Co. at Manchester rather disproves this. The company, formerly working on a 48-hr. week schedule, dropped to 40-hr. On this shorter schedule, which was started Jan. 1, the 1500 employees are assembling two to three chassis per day more than on the longer schedule. This is largely due to a better spirit of co-operation among the workers, the majority of whom realize the benefit of shorter hours. An investigation showed that instead of these workers spending their time at the saloon they were taking up such pastime as chicken raising and gardening. Many of the garden spaces doubled as soon as the extra spare time was allowed, and there was a great demand for lumber for building chicken coops which indicated a healthy disposition on the part of the worker. There was no increase in drunkenness. In fact, the contrary prevailed.

British manufacturers have already realized that production was very low in the early morning hours, particularly from 6 until 9 a. m., when many of the employees returned home for breakfast. There has been a good deal of opposition to starting work at 8 on the ground that it calls for an earlier breakfast than the Britisher has been accustomed to, but already the benefit of such a move is being realized, and opposition from the housewife is passing.

France is beginning to realize that the heavy noonday meal is a manufacturing error, and some factories where 1½ to 2 hours are taken off at noon so that the workers might go home for the heaviest meal of the day realize that they are losing two of the best hours of sunshine, and that after the workers return it is an hour or perhaps longer before they are back on an efficiency basis, because of the heavy meal eaten. The ½-hour luncheon is desired by the more progressive French makers, but they realize the difficulty ahead in overcoming the tradition of the French home in regard to the noonday meal.

The automobile industry in England is bound to suffer more because of the labor upheaval than it would have previ-

ous to the war. Such places as Coventry, for example, have increased their population more during the war than at any time previously, and have become trade centers as well as labor centers, and so the automobile industry has come more under labor problems than ever before.

The present working-out of the short week seems to draw attention to two factors: First, the upsetting of domestic arrangements that have been traditional; and, second, the curtailing of minor privileges which the individual has for years enjoyed. The upsetting of home routine by the earlier breakfast and the shorter meal hour has been referred to.

The curtailing of individual privileges has more to do with the factory. The tea hour or half-hour is being eliminated. The rule against smoking must be enforced, and with the shorter week it will be necessary for the worker to work at higher efficiency than ever before. Some of the factories have reduced the working temperature so as to stimulate activity. Others have insisted on medical examinations and hospital service so as to increase the usefulness of the worker. For a time the worker is going to object to many of these innovations on the ground that it is interfering with his individuality and the employer has a problem on his hands to convince him that it is for his benefit as well as the factory.

Contract Bill Again Held Up

WASHINGTON, Feb. 19—The bill providing for the payment of informal contracts which was passed by the Senate and reported to the House for approval by the Conference Committee was ordered back to the Committee by the House yesterday for the elimination of certain amendments. Only very prompt action by Congress can now secure the passage of the bill during the present session.

Michigan Copper & Brass Profits $186,507

DETROIT, Feb. 17—The balance sheet of the Michigan Copper & Brass Co. for 1918 shows net profits totaling $186,507.88 on outstanding capital stock of $991,350. After reserving $20,000 for federal taxes and paying dividends of $29,740 at 4 per cent, the company's total surplus at the beginning of the year stood at $1,570,776.91. It shows a property account on Dec. 31, 1918, of $1,407,407, of which $276,791 is in a new rod mill constructed during the war. Current assets are placed at $3,124,137 and total assets $5,033,028. Current liabilities are $2,470,901. D. M. Ireland is president and Alonzo Ewing, vice-president and general manager.

Christian Girl Back at His Desk

CLEVELAND, Feb. 19—Christian Girl, president of the Standard Parts Co., who has been South recuperating from a slight operation this fall, is again in good health, and will resume his business duties in April.

Ocean Flight Topic at Aero Dinner

Two Entries for Atlantic Flight Already In—Dinner Attended by 800 Fliers—Dirigibles Approved for Commerce

NEW YORK CITY, Feb. 19—That two entries have been registered for the transatlantic flight with the Royal Aero Club of Great Britain was announced at the thirteenth annual banquet of the Aero Club of America, held in this city tonight, and attended by upward of 800 aviation enthusiasts.

So far no other specific entries seem to have been received for the trans-ocean flight.

Capt. Edward Rickenbacker recommended that some form of memorial be erected in the cemetery at Toul, France, where many of our American aviators are buried. He also suggested that some form of memorial be erected at a suitable place in America to the memory of these aviators.

It was the general belief of practically all of the aviators present that the Atlantic would be crossed this year. The value of the dirigible as a vehicle for long distance transportation was favorably commented upon. Over a dozen American Aces, recently returned from the front, were guests at the dinner.

General Menoher, new chief of the air service, spoke favorably on commercial aviation, as follows:

"I look to see in the near future, in a matter of months only, perhaps, the command of the line of battle exercised from the air instead of from some dugout out of sight and more or less out of touch with the situation."

"As in the case of any commercial activity, there should be constant endeavor toward standardization. To adequately accomplish this there should be:

"A—A national aircraft engineering standards commission working in conjunction with our Bureau of Standards, which commission should be in touch with a similar internationl standards commission.

"B—A national aerial digest bureau, charged with the collection and publication of data which mark new advances in the development and use of aircraft and aircraft material, and the results of physical and medical research pertaining thereto.

"C—The publication of a revised, up-to-date aeronautical dictionary.

"D—The formation of aero clubs, either branches of or affiliated with a central national association, which should have a directorship consisting of representatives from the army, navy, postoffice, weather bureau, Smithsonian Institution, National Advisory Committee of Aeronautics, Aero Club of America, American Society of Aeronautical Engineers, Manufacturers' Aircraft Association, intercollegiate representation, etc."

Brazil Reduces Duty on U. S. Tires

WASHINGTON, Jan. 27—The Congress of Brazil has adopted the usual authorization for an executive decree to continue the preferential tariff treatment of some American products during 1919. The articles on which the reduction is granted will be specified in a separate decree, and will probably be similar to the list of 1918, when a reduction of 20 per cent was allowed in the duties on rubber tires, among other commodities.

38,052 Government Vehicles to Be Delivered

WASHINGTON, Feb. 15—On Jan. 9, practically two months after the signing of the armistice, there were on order and still undelivered to the Government a total of 38,052 automotive vehicles as follows:

G. M. C. 1-ton ambulances	1,834
G. M. C. standard 1-ton trucks	4,921
1½-ton standard trucks	3,090
Standard 3-, 4- and 5-ton trucks	9,068
Special 2- and 3-ton trucks	7,782
Limousines	15
Motorcycles	9,408
Standard 1½-ton trucks for domestic use	563
Standard 3-ton and heavier trucks for domestic use	1,371
	38,052

At the time of the signing of the armistice there were on order and still undelivered to the Government 138,424 automobiles and trucks; 96,952 of this number was canceled, and the balance, 41,472, was to be delivered at a future date.

Outlook Windshields to Be Exhibited at Lyons Fair

CLEVELAND, Feb. 19—Outlook windshields, made by the Outlook Co. of this city, will be exhibited at the forthcoming Lyons Fair (France) by Dutrieu & Co., Paris, distributers of the line.

Mechanical Engineers to Hold Meeting

NEW YORK, Feb. 20—Afternoon and evening meetings of the American Society of Mechanical Engineers are scheduled for Feb. 24. Subjects to be discussed are the application of electrical control to gate valves and the application to industry of the personnel work of the U. S. Army. Motion pictures and lantern slides will be shown and proceedings terminate with a buffet supper.

Fisk Reduces Common to $25 a Share

CHICOPEE FALLS, MASS., Feb. 19—At the annual meeting of the Fisk Rubber Co. to-day stockholders voted to change the par value of the common stock from $100 to $25 a share. They also authorized the reduction of the capital stock by $770,100 through the retirement of 7,701 shares of first preferred stock now held in the treasury. This stock was purchased by the company. All officers and directors were re-elected.

According to the company's financial statement for the year ended Dec. 31 last, net sales for 1918 amounted to $36,682,163. The total surplus for the year was $4,425,923, approximately $400,000 more than 1917. After deducting costs, interest on borrowed money, etc., a net surplus of $3,760,279 remained.

Mexican Bank Law Secures Credit

Bill to Develop National Banks — To Eliminate Present Foreign Cash Basis

WASHINGTON, Feb. 18—Exporters of automotive products to Mexico will benefit by the new banking system in that country planned by President Carranza in a law recently submitted to the Mexican Congress. The bill provides for development of national banks, broadening the Mexican banking system and completely revising the banking law of 1897. If passed, the bill will undoubtedly eliminate the present strictly cash basis with American manufacturers now insisted upon in their Mexican export business. The bill is particularly designed to establish a sole bank of emission and other banks for the development of specific industries, to stabilize the unsettled money market resulting from the European war, establish credits on a fair basis and promote loans at a reasonable rate of interest.

Has Few National Banks

Mexico, during the past few years, since the fall of President Diaz, has practically been without national banking institutions and has been dependent on private banking organizations whose activities are limited almost entirely to the issuance, purchase and sale of foreign exchange, and a few commercial credit transactions. As a result, commercial credits and advances on bills of lading have been made only at exhorbitant rates. Finances for import shipments have been difficult to secure. Consequently, both the exporters into Mexico and the Mexican importers have had difficulty in stabilizing their business in that country and commerce has suffered. In fact, at present American trade with Mexico has been on a cash basis with but few exceptions. American commission merchants and manufacturers' agents have had to insist on partial cash payment of the invoice value of import orders with the balance usually covered by sight drafts and documents payable at New York or the Mexican port of entry.

The Mexican Department of Finance, however, has determined to assist Mexican business men, and it is certain that under the new law the bulk of Mexican import trade will be done in the future on a credit basis. Our proximity gives us a certain advantage in competition with European manufacturers, but the latter are preparing to enter the field and extend credit, while American makers, according to the Department of Commerce, are still trying to maintain a cash basis.

Under the proposed law the following classifications of banking institutions of credit are made:

Sole bank of emission.
Mortgage banks to make loans secured by urban or rural real estate.
Banks of promotion to facilitate or encourage mining, industrial and commercial operations.
Agricultural banks to make loans for the purchase of equipment or expense of operation, to be secured by the products and crops of the farm.
Petroleum banks to make loans for equipment and operation to petroleum exploitation enterprises.

The purpose of this classification is to promote more efficient response to the needs of the different lines of production and so guarantee ready capital for the promotion of industry, commerce and agriculture. Under the new law, a minimum capitalization is specified of at least $250,000 in the case of agricultural banks, banks of deposits and banks of promotion, and $500,000 with the mortgage and petroleum banks to be contributed at once.

Dirigibles for Commercial Flights

(*Continued from page* 437)

wireless system extending over the complete area covered by the planes.

AUTOMOTIVE INDUSTRIES is one of the most enthusiastic supporters of commercial aviation, but it does not want to see the art given a body blow while in its swaddling garments, due to the over-enthusiasm of some stock promoter who is looking only toward his pocketbook, and not toward the future of this field of transportation. The exploitation of commercial aviation by a few such promoters would do an injury that could scarcely be overcome in 10 years.

These are days when the Government should be carrying on many of the activities which are fundamentals in successful aerial transportation. These fundamentals must be started long in advance of the time when planes are ready to do the work. If we had a complete, thoroughly worked out system of landing fields, wireless, signals, meteorology, aerial navigation, etc., it would be possible with present planes to carry on successful systems of mail and express handling. Without these no system can be successful. The vehicle is now as a vehicle of transportation very far in advance of the necessary systems which are needed in conjunction with it. By the time adequate measures are completed for carrying on aerial navigation, commercial types of planes will be developed on a par if not far beyond that of the system for control.

Dirigible Logical for Distance Flights

In aerial transportation over any country such as the United States there must also be carefully weighed the relative field for the airplane and the dirigible. For long distance passenger travel between New York and Chicago, the dirigible to-day seems the logical machine. With it, it would be possible to carry 300 persons with baggage, between these cities on a night journey. The trip could be made with complete safety. On the other hand, such a trip with airplanes would be accompanied with great danger until all of the necessities mentioned surrounding commercial aviation have been accomplished. Even then the safety factor with a dirigible is amazingly more attractive than that of the airplane, unless there is developed some other means of increasing the safety element.

The development of airplane pilots for commercial use is a work that must be done at once. The majority of our pilots who fought in the war have no thought of entering commercial aviation. Many of them are college men to whom the role of an aerial chauffeur has no attractions. Some of them have expressed themselves as fortunate if they never have to ride in an airplane again, but if war broke out they would volunteer at once.

With these men there is a great difference between war and commercial aviation. It will be necessary to develop commercial pilots, the same as we have engineers for our passenger and freight trains, drivers for our motor trucks and chauffeurs for our automobiles. These pilots will do the job for the weekly wage rather than for any aerial thrills. The work must be brought on to a sound business basis.

The stunt in all its forms will be eliminated, and the only requirement will be that the aerial vehicle, in whatever form it may be, will start on schedule, make its trip on schedule, arrive at its destination on schedule, irrespective of wind, rain, fog, or snow. Only when this is accomplished will aerial commercial navigation be a success.

Canada Importer of Tractor Engines

Takes 60 Per Cent of Exports —New Zealand and France Next

WASHINGTON, Feb. 17—Exports of gasoline and steam tractor engines during December, 1918, totalled 1816, of which 1734 were gasoline and 82 steam. Shipments to Canada were in excess of 60 per cent of the total number exported, that country taking 1181 gasoline and all of the steam tractor engines.

The average prices paid by the different nations vary considerably, with $1,125 per engine by England, $713 by Canada, $700 by France and but $418 by New Zealand.

Following is the list of tractor engines exported in December:

Countries	Gasoline		Steam	
	No.	Dollars	No.	Dollars
Denmark	2	6,800	..	....
France	131	91,704	..	....

Men of the Industry

Changes in Personnel and Position

Dedell Heads Firestone Advertising

AKRON, Feb. 17—J. R. Dedell, until recently connected with the Corday & Gross Advertising Co., Cleveland, has been appointed advertising manager of the Firestone Tire & Rubber Co., Akron.

—

Capt. Carl V. Richardson has opened an office at 1305 Monadnock Block, Chicago. He will specialize on consultations and designs of internal combustion engines, tractors and trucks. Previous to army service, he was experimental engineer with the Parrett Tractor Co. and designing engineer with the Buda Co.

—

A. A. Gloetzner has been elected vice-president of the Covert Gear Co., Inc., Detroit. He will also retain his present duties as chief engineer and manager of sales.

—

Fred B. Sides has been appointed assistant sales manager of the Hupp Motor Car Corp. He joined this company in 1915 as office manager.

—

E. J. Quirk, who has been in government service, has returned to the retail sales department of the Detroit office of the Studebaker Corp.

—

Lewis G. Harris has been appointed sales manager of the West Detroit Auto Sales Co., to succeed J. L. Cobaugh, who has resigned.

—

William H. Little has resumed his duties as general manager of the Scripps-Booth Corp. During the war he was supervisor of engine production for the army in the Chicago district.

—

A. H. Schiappacassee, for six years connected with the engineering and service departments of Dodge Brothers, has resigned to become assistant manager and research engineer of the Brisk-Blast Co., Monroe.

—

F. J. Fisher has been released from the Motor Transport Corps and has resumed his duties as secretary and treasurer of the Standard Motor Truck Co., Detroit.

—

Birkett L. Williams has been appointed sales manager of the truck department of the Grant Motor Car Corp., Cleveland.

—

Goodrich Vice-President Back From Service

AKRON, Feb. 15—Lt. Col. A. B. Jones, vice-president of the B. F. Goodrich Rubber Co., who has just returned home, left here in August to take charge of the motor transport work of the Red Cross in France, when it formed its own department to handle its supplies. In October, Colonel Jones succeeded Colonel Harvey Gibson as commissioner for France, when Colonel Gibson was made chairman of the commission for Europe.

Jacobsson Sails for Scandinavia

NEW YORK, Feb. 17—Birger Jacobsson, representing the J. B. Crockett Co., Inc., exporters, sails this week for Scandinavia on a business trip.

—

Capt. E. A. Callanan has been appointed general purchasing agent for the Cleveland Tractor Co., Cleveland. For the past 15 months he has been in charge of the production of the De Haviland battle planes at the Dayton-Wright plant, Dayton. Previous to that he was for five years assistant purchasing agent for the Willys-Overland Co., Toledo, and was later a manager in the branch department of that organization.

—

Arthur C. Brenckle, president Olympian Car Co., Milwaukee, distributer of the Olympian in Wisconsin and upper Michigan, was elected a director of the manufacturing corporation at the annual meeting held in Pontiac on Feb. 14.

—

George C. Baldwin, formerly with the Saxon Motor Car Corp., has been appointed field manager for the United Motors Service, Inc. This position includes the distribution of technical information and records, advertising and supervision of all branches and authorized distributers. Besides his connection with the Saxon corporation, Mr. Baldwin has been service manager for the Cadillac Motor Car Co. and the Studebaker Corp.

—

J. L. Hardig, formerly advertising manager of the Remy Electric Co., has been appointed assistant advertising manager of the Motor Equipment Division of the United Motors Corp., Detroit.

—

A. E. Maltby has resigned as branch manager of the Winton Co., Cleveland, effective March 1, to become vice-president and general manager of the Bigelow Willey Co., Philadelphia, distributer of Paige passenger cars and trucks. Mr. Maltby is now serving for the third term as president of the Automobile Trade Association.

—

Mason, of Mason Tire Co., Dead

CLEVELAND, Feb. 17—Daniel N. Mason, founder of the Mason Tire & Rubber Co., Kent, Ohio, and also one of the founders of the Mason Cotton Fabrics Co., died at his home here Thursday of pneumonia. He was 31 years old and leaves a widow and one child.

Coe Made Anderson Vice-President

NEW YORK, Feb. 15—Charles F. Coe has been elected vice-president and general sales manager of the Anderson Motor Co., Rock Hill, S. C. Up to within two weeks ago he was manager of the Chevrolet Motor Co. of New England, with headquarters in Boston. He assumes his new duties March 1.

—

J. Frank Keegan, formerly with Albertson & Co., Sioux City, has joined the Spencer Metal Products Co., Spencer, Ohio, as traveling representative for the Central West.

—

Lt. Fred M. Young, who has recently returned from overseas duty in the air service, has become associated with the Perfex Radiator Co., Racine, as sales engineer.

—

G. W. Williams, Jr., has resigned from the Bureau of Aircraft Production to take over the duties of advertising manager of the United Motor Service, Inc. Before entering Government service eighteen months ago he was with the advertising department of the Electric Storage Battery Co., Philadelphia, for seven years.

—

Harry E. Weiner has been appointed retail sales manager of the New York branch of the Maxwell Motor Sales Co. He will handle both Chalmers and Maxwell lines.

—

E. W. Kruste, formerly with the Four-Wheel Drive Auto Co., has been appointed a district representative of the Standard Motor Truck Co., Detroit. His territory includes Wisconsin and Minnesota.

—

Maus Made Chairman of Foreign Trade Division

CHICOPEE FALLS, MASS., Feb. 17—John B. Maus, export manager of the Fisk Rubber Co., has been appointed chairman of the Foreign Trade Division of the Springfield Associated Interests, an assocation working for the better interests of foreign trade.

—

Four Old Employees Return to Pennsylvania Rubber Co.

JEANNETTE, PA., Feb. 19—Four employees of the Pennsylvania Rubber Co., who have recently been discharged from service, have returned to their former positions. Lieut. George Blair, who has been in the Naval Aviation for the past 18 months, has resumed his position as manager of the Philadelphia branch. P. F. Armitage, in the Naval Reserve Force for the last year, has again taken up the northeastern Pennsylvania territory, with headquarters at the Philadelphia office. Milton H. Batz, who was with the company for eight years until he went into the army eight months ago, is now back on his territory in western New York State, and William E. Little, who for the past six months has been with the Motor Instruction Division, is back on his territory in central Pennsylvania.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Harley-Davidson to Expand

MILWAUKEE, Feb. 17—Enlargement of the plant of the Harley-Davidson Motor Co. is forecast by the fact that the company has engaged the Federal Engineering Co., Milwaukee, to make sketches and estimates of a proposed five-story addition, 50 x 150, at Thirty-eighth and Chestnut Streets to cost about $100,000.

National Tire & Rubber Insures Employees

EAST PALESTINE, O., Feb. 15—The National Tire & Rubber Co. has presented each of its employees with a life insurance policy paid entirely by the company, and increasing automatically as the employee's term of service increases. It provides for the payment of the full amount of the policy to the beneficiary in case of death of an employee, and in case of permanent disability the full amount of the policy will be paid in monthly installments. The policy may also be transferred and continued by the holder after leaving the employ of the company.

At the present time the addition to the National Tire & Rubber factory is going ahead rapidly, and it plans a greatly increased production next season. It is also bringing out two new brands of tires.

Pony Tractor New Concern

LAPORTE, IND., Feb. 18—Articles of incorporation have been filed by the Pony Tractor Co., with a capital stock of $100,000. The concern will manufacture, buy and sell, as well as assemble, farm tractors. The promoters are John S. Lingard, George Cummerford and M. E. Leliter, all of this city.

Mexico as Source of Petroleum and Its Products

(*Continued from page* 423)

eral order was issued that no lubricating oil should be thrown away. All the used castor oil in the squadrons was collected in barrels and sent to the Meurisse factory for treatment. In the regenerating process the loss never exceeded 10 per cent. Indeed, the refining factory could frequently work with a loss of only 5 per cent. Although castor oil was the first to be treated in this way, mineral oils were also taken and regenerated in the same way.

Details of the process are not available for publication. The oil is not only filtered but regenerated, and in doing this certain chemicals have to be used. The nature of these chemicals and the method of using them are kept secret. This system, which would never have had an opportunity of coming forth in any but a war period, has been responsible for economizing an immense quantity of oil. Previous to its adoption oil was merely filtered, and then used for some inferior purpose. The Meurisse system appears to be the only one allowing used oil to take the place of new.

Ajax Profits Less This Year

NEW YORK, Feb. 15—The Ajax Rubber Co., Inc., showed an increase in its income for the year of $960,075 over last year, but a decrease in $266,225 in its profits after the necessary deductions for taxes, dividends, etc., were made. The balance sheet for the year ending Dec. 31, 1918, as compared with that ending Dec. 31, 1917, follows:

Income Account

	1918	1917
Profits	$2,915,368	$1,955,293
Provision for Federal war profits and income taxes	1,700,000	495,000
Net income	$1,215,368	$1,460,293
Dividends	852,000	830,700
Surplus	$363,368	$629.593
Previous surplus	768,840	139,247
Total surplus	$1,132,208	$768,840
Assets		
Land, buildings, machinery, etc., less depreciation	$2,142,536	$1,862,605
Other property	17,410	....
Patents, good will, etc.	1,874,875	1,874,875
Inventories	3,917,368	5,424,827
Accounts receivable	2,165,420	2,234,585
Liberty bonds	477,838	148,000
Cash in banks and on hand	363,613	257,341
Deferred charges	112,571	118,213
Total	$11,071,634	$11,920,449
Liabilities		
Capital stock	$7,100,000	$7,100,000
Accounts payable	832,801	3,401,493
Taxes payable (Wisconsin)	75.734	....
Bonuses payable	230,889	155,114
War profits and income taxes (estimated)	1,700,000	495,000
Surplus	1,132,208	768,840
Total	$11,071,634	$11,920,449

At the directors' meeting, F. E. Dayton, formerly secretary, was elected vice-president. W. J. Jackson succeeds Mr. Dayton as secretary. Otherwise there was no change in the officers or board of directors.

France Prohibits Auto Imports

(*Continued from page* 439)

in francs, paid in France, of a sum of 8,437,500 francs, being the cost to the Government of the said vehicles paid in dollars in America.

6—Receipt by the Government by way of net profit on the transaction of a sum of 843,750 francs.

7—It is estimated that French automobile dealers established in France would make a gross profit from the sale and distribution of these automobiles of a sum of 5,850,000 francs.

8—Continuous employment would be secured for a very large number of demobilized soldiers.

9—The Ford company estimates that its costs for wages of assembly and other expenses for completing these automobiles and distributing them to dealers would amount to a sum of about 4,000,000 francs.

The Ford company claims that the refusal of the Minister of Industrial Reconstruction to allow these automobiles to go into service is resulting in:

1—A loss to the French nation of the utility of 4500 automobiles available in private ownership for immediate service in war devastated areas.

2—A loss of recovery of capital and revenue to the French Government of over 18 million francs.

3—Loss of immediate employment to many hundreds of demobilized soldiers.

4—Suspension of the resumption of commercial business, upon which the prosperity of the French people is dependent.

5—Sacrifice of the good will and commercial friendship of American allies.

This campaign of the Ford company is unprecedented; but it had to be admitted that foreign dealers established in France have been provoked by the uncompromising attitude of French manufacturers, who have used every weapon in order to shut out and discredit the foreigners. It is thought that after this attack by the Ford company the French Government cannot long delay in giving a decision. One important importer of foreign cars maintains that the greatest injustice is not the present prohibition, or the 70 per cent tax, but the continued uncertainty. Establishments have to be maintained in view of the possibility of business at some later date, but at present nobody knows whether these business relations can be re-established in a few weeks or in a few years.

French automobile manufacturers want substantial protection for one year, and after that reciprocity with a maximum import duty of 10 per cent; by this they mean that they would admit, for instance, American automobiles free of duty or with any duty not exceeding 10 per cent, providing that America did the same. They would not be interested, however, in a 30 per cent duty in America which obliged them to impose a 30 per cent duty in France.

This was the statement made to me by Louis Delage, one of the leading French manufacturers, who declared that these views were generally shared by members of the Syndicat of Automobile Manufacturers and had been submitted by them to the French Government. The French manufacturers want protection for one year in order to enable them to get their factories on to a peace basis, and to prevent their market being flooded while they are unable to meet the local demand. Reciprocity is considered to be the most satisfactory solution. It would not work equally well in every case, but, on the whole, the results should be good. A reciprocal 10 per cent duty between France and America would rather be to the advantage of America than to France, for it would allow all the cheaper grades of American cars to be sold in France while only some of the higher class French cars could be sold in America.

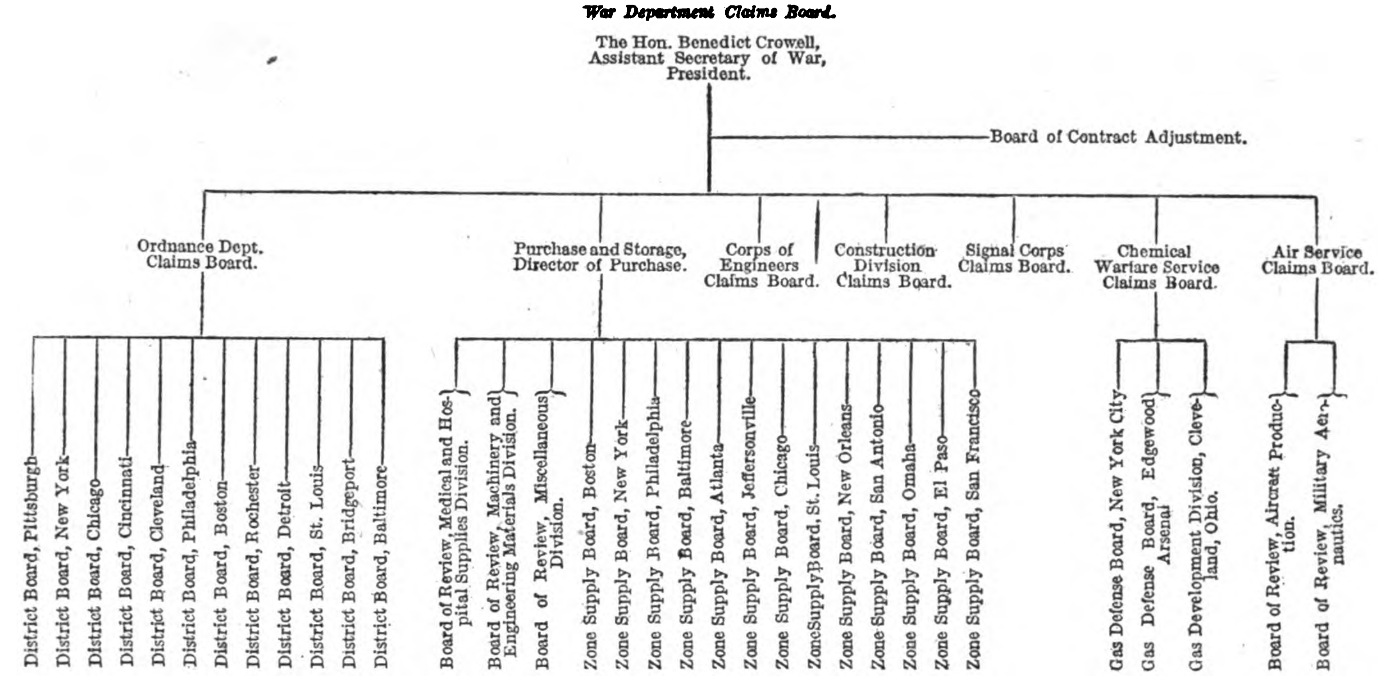

Chart of the organization of the War Department Claims Board

War Department Claims Board Organized to Adjust and Review War Contracts

WASHINGTON, Feb. 14—The composition of the War Department Claims Board, together with the list of boards supervising and passing upon adjustment of War Department contracts, has been made public by the War Department, and is as follows:

War Department Claims Board.

President, Hon. Benedict Crowell, the Assistant Secretary of War, director of munitions.

Mr. G. H. Door, assistant director of munitions.

Brig. Gen. George W. Burr, assistant to Maj. Gen. Goethals, director of purchase, storage and traffic.

Brig. Gen. Herbert M. Lord, director of finance, purchase, storage and traffic division.

Lieut. Col. Herbert H. Lehman, assistant to Maj. Gen. Goethals, director of purchase, storage and traffic.

Special members: Mr. W. H. Davis. Col. C. A. McKenney, Maj. H. L. Goodhart, Maj. Harry D. Rawson, Capt. Arthur Day.

Recorder: Maj. Erskine Bains.

The function of this board is to supervise and co-ordinate the work of contract adjustment throughout the department. Through its special representatives sitting with the bureau boards all contract adjustments of the department are subject to its scrutiny and approval, and adjustments involving matters of policy and of particular difficulty and importance are brought before the full board for decision.

Board of Contract Adjustment.

Lieut. Col. Herbert H. Lehman, assistant to Maj. Gen. Goethals, director of purchase, storage and traffic.

Lieut. Col. E. F. Malone.

Lieut. Col. C. B. Garnett.

This board passes on the questions of contract adjustment on which the contractor and the local and bureau boards of the department have been unable to reach agreement.

Ordnance Bureau.

Ordnance claims board—Brig. Gen. W. S. Peirce, Col. R. P. Lamont, Col. G. H. Stewart, Col. Earl McFarland, Maj. John R. Delafield.

This board reviews the action of the ordnance district boards.

District Claims Board.

1. Baltimore—Maj. A. V. Barnes, Capt. R. W. Smith, Maj. L. B. Webster, Capt. F. E. Baldwin, Mr. J. J. Nelligan, Mr. E. G. Baetjer.
2. Bridgeport—Maj. B. A. Franklin, Maj. Frederick Payne, Capt. Miller Brainard Charles G. Sanford, Edmund C. Wolfe, David H. Day, Charles W. Graham.
3. Boston—Levi H. Greenwood, Lieut. Col. O. S. Lyford, Maj. Herbert S. Brussel, Maj. A. S. Douglass, Mr. Stuart W. Webb, Mr. Charles M. Davenport, Mr. Atherton D. Converse.
4. Chicago—Mr. Edmund A. Russell, Lieut. Col. E. E. Arison, Maj. Frank R. Bacon, Mr. James W. Lyons, Mr. John J. Mitchell, Maj. F. R. Schenck, Mr. George S. Pines.
5. Cincinnati—C. L Harrison, George S Raydock, B. W. Lamson, R. K. Leblond, O. De Gray Vanderbilt, Carl M. Jacobs, Stanely G. Rowe, F. H. McClellan.
6. Cleveland—Samuel Scovil, W. B. McAllister, Philip P. Merrill, Amos B. McNairy, Joseph H. Scobell, Judge Thomas H. Strimple, Maj M. F. Loomis.
7. Detroit—F. J. Robinson, C. C. Huyette, C. C. Jenks, Maj. C. W. Owston, Maj. P. C. Thomas, Henry M. Campbell, Maj. S. L. Depew, Capt. J. G. Dalgleish.
8. New York—Mr. G. J. Roberts, Maj. C. S. Reed, Mr. B. Goldsmith, Maj. C. C. Smith, Mr. R. A. C. Smith, Lieut. Col. Arthur Adams.
9. Philadelphia—John C. Jones, Capt. Malcolm F. Ewen, Maj. R. M. Appleby, Isaac Hathaway Francis, Maj. F. M. Masters, John Dickey, Jr., Mr. Alexander H. Carver.
10. Pittsburgh—R. M. Drave, Maj. H. B. Scovil, Maj. J. F. Drake, Harrison Nesbitt, George S. Oliver, Charles Gulentz.
11. Rochester—Frank S. Noble, Maj. J. L. Crane, Mr. Langdon Albright, Maj. J. J. O'Connell, Mr. Herbert J. Sinn, Joseph W. Taylor, George A. Carnshan.
12. St. Louis—Mr. M. E. Singleton, Maj. E. S. Ready, Maj. B. S Bope, Mr. W. F. Carter, Mr. C. W. Nelson, Mr. Davis Biggs.

Office of the Director of Purchase and Storage.

All final contract agreements or settlements are personally approved by Brig. Gen. William H. Rose, Director Purchase.

Board of Review for Termination Agreements handled by the following divisions under the office of the director of purchase: Clothing and Equipage Division, General Supplies Division, Subsistance Division, Remount Division, Motors and Vehicles Division. Raw Materials Division—Col. H. S. Kilbourne, Capt. William E. Lee, Capt. R. D. Stephens.

Board of Review for Medical and Hospital Supplies Division. office of the director of purchase—Lieut. Col. J. F. Fletcher, Capt. J. Van Putten, Jr., Maj. Frank L. McCartney, Maj. G. W. Wallerich, Capt. Harry G Gunther, Capt. John C. Schweiger.

Board of Review for Machinery and Engineering Materials Division. office of the director of purchase—Col. Earl Wheeler, Lieut. Col. J. E. Long, Maj. George A. Bentley, Maj. Ira D. Hough, Maj. H. W. Eels, Maj. C. B. Loomis, Maj. H. McC. Yost, Capt. B. H. Arnold.

Zone Board of Review.

Atlanta, Ga., Transportation Building—Maj. G. M. Alden, Quartermaster Corps, Maj. L. M. Thibadeau, Quartermaster Corps; Maj. E. de T. Ellis, Infantry; Capt. J. A. Graham, Quartermaster Corps.

Boston, Mass., 108 Massachuetts Avenue—Maj. J. W. Blunt Quartermaster Corps; Maj. W. H. Rhoads, Quartermaster Corps; Capt. Leroy Holder, Quartermaster Corps; First Lieut. A. A. Lucey, Quartermaster Corps; Mr. George E. Barnard.

El Paso, Tex.—Capt. F. C. Allen, Quartermaster Corps; Capt. F. C. Shelley, Quartermaster Corps; Mr. W. H. Dent.

Jeffersonville, Ind., Meigs Avenue—Maj. M. T. Levey, Quartermaster Corps; Maj. L. L. Sims, Quartermaster Corps; First Lieut. Henry Pirtle, Quartermaster Corps; First Lieut. L. C. Clarke, Quartermaster Corps.

New Orleans, La., Audubon Building—Maj. P. T. Murphy, Quartermaster Corps; Maj. E. I. Sharp, Quartermaster Corps; Capt. F. L. Hester, Quartermaster Corps; Second Lieut. S. Roccaforte, Quartermaser Corps; Mr. Benjamin Coswell Cassenas.

Omaha, Neb., Army Building—Maj. William H. Faringly, Quartermaster Corps; Lieut. Col. P. H. Holcombe, Quartermaster Corps; First Lieut. George E. Comins, Quartermaster Corps; Mr. C. E. Adams, inspector, Quartermaster Corps; Mr. Fred S. Knapp.

Philadelphia, Pa., Twenty-first and Oregon Avenue—Maj. Remi Hueper, Quartermaster Corps; Maj. Archibald H. Bronson, Quartermaster Corps; Maj. Herbert Knox Smith, Quartermaster Corps; Maj. James M. Taft, Quartermaster Corps; Capt. Otis S. Carroll, Quartermaster Corps.

St. Louis, Mo., Second and Arsenal Streets—Maj. R. Field, United States Army retired; Maj. J. W. Byrnes, Quartermaster Corps; Capt. J. P. Keleher, Quartermaster Corps; Second Lieut. G. Rosenbaum, Quartermaster Corps; Mr. A. J. Davis.

San Antonio, Tex., General Supply Depot—Maj. E. O Baldwin, Quartermaster Corps; Maj. T. O. Baker, Quartermaster Corps;

Calendar

ENGINEERING

S. A. E. Meetings

Feb. 27—Kansas City. S. A. E. tractor meeting at Sweeney School Auditorium; dinner at Hotel Baltimore.

March 5 — Minneapolis Section, S. A. E.—Hotel Radisson. "Tractor Service and Sales."

April 2—Minneapolis Section, S. A. E. — Hotel Radisson. "Implements Designed for Tractor Belt Power and Their Characteristics."

MOTOR SHOWS

Feb. 17-22 — Louisville, Ky. Louisville Auto Dealers' Assn.

Feb. 17-22—Des Moines, Iowa. Tenth Annual, Des Moines Automobile Dealers' Assn. C. G. Van Vliet, Manager.

Feb. 17-22 — Pittsfield, Mass. Pittsfield Automobile Dealers' Assn., State Armory. James J. Callahan. Manager.

Feb. 17-22 — Passenger Cars; Feb. 24-27, Trucks—South Bethlehem, Pa. Lehigh Valley Auto Shows Co. J. L. Elliott, Manager.

Feb. 17-22—Grand Rapids, Mich. Grand Rapids Automobile Business Assn. E. T. Conlon, Manager.

Feb. 17-22—Seattle, Wash. Cars, Motor Car Dealers' Assn., State Armory. A. G. Schaeffer, Manager.

Feb. 18-22—Baltimore, Md. Baltimore Automobile Dealers' Assn. and Automobile Club of Maryland, Fifth Regiment Armory, H. M. Lucius, General Manager.

Feb. 18-22 — Oklahoma City, Okla. Automotive Show. R. H. Haun, Manager.

Feb. 18 - 22 — Wichita, Kan. Wichita Automobile Dealers' Assn.

Feb. 19-22 — Evansville, Ind. Cars, Evansville Automobile Dealers' Assn. Coliseum.

Feb. 22-March 1 — Hartford, Conn. Hartford Automobile Dealers' Assn., Inc., Broad Street Armory. Ben F. Smith, Manager.

Feb. 22-March 1—Atlantic City, N. J. Auto Trades Assn. of Atlantic City.

Feb. 22-March 1—New Castle, Pa., Lawrence County Association of Automobile and Accessory Dealers.

Feb. 22-March 1—Reading, Pa. Reading Auto. Trade Assn.

Feb. 23-March 1—Cedar Rapids. Auditorium, Automobile Dealers' Assn.

Feb. 24-March 1—Burlington, Ia. Second Annual.

Feb. 24-March 1—Kansas City, Mo.—Kansas City Motor Dealers' Assn. E. E. Peake, Manager.

Feb. 24-March 1—Springfield, Mass. Automobile Dealers' Assn. Harry W. Stacy, Manager.

Feb. 24-March 1—Springfield, O. Auto. Trade Assn.

Feb. 24-March 1—Portland, Ore. Ninth Annual Dealers' Motor Car Assn., Automobile Palace. M. O. Wilkins, Manager.

Feb. 24-March 1—Duluth, Minn. Duluth Automobile Dealers' Assn.

Feb. 25-March 1 — Erie, Pa., United States Garage.

Feb. 26-March 1—Mason City, Ia. Fifth Annual, Mason City Auto Show Assn.

Feb. 26-March 1—Madison, Wis. Seventh Annual, Automobile Dealers' Division of Madison Assn. of Commerce, Union Transfer Bldg.

Feb. 26-March 1—Quincy, Ill. Cars, Quincy Automobile Trade Assn. Armory.

Feb. —Wheeling, W. Va. Automobile Show at Market Auditorium.

March 1-15—New York Aeronautical Exhibition, Manufacturers' Aircraft Assn., Madison Square Garden and 69th Regiment Armory.

March — Scranton, Pa. Thirteenth Regiment Armory, Scranton Automobile Assn.

March—Utica, N. Y. Utica Motor Dealers' Assn. W. W. Garabrandt, Manager.

March—Philadelphia, Pa. Philadelphia Automobile Trade Assn. Passenger cars.

March 1-8—Detroit, Mich. Detroit Automobile Dealers' Assn. H. H. Shuart, Manager.

March 3-5—Quincy, Ill. Trucks and Tractors. Armory.

March 3-8 — Muskegon, Mich. Third Annual, Armory, Muskegon Lodge No. 274, B. P. O. E. John C. Fowler and George M. Friant, Managers.

March 3-8—Columbus, O. Columbus Automobile Show Co., Memorial Building. W. W. Freeman, Manager.

March 3-8—Scranton, Pa. Ninth Annual, 13th Regiment Armory, Scranton Automobile Assn. Hugh B. Andrews, Manager.

March 3-8—Buffalo, N. Y. Buffalo Automobile Dealers' Assn.

March 5-8—Lancaster, Pa. Automobile Trade Assn., Rowe Motor Co.'s Bldg. R. W. Shreiner, Manager.

March 8-15 — New Brunswick, N. J. Armory, New Brunswick Motor Trade Assn. William Kuehle, Manager.

March 8-15 — Philadelphia, Pa. Philadelphia Automobile Trade Assn., Commercial Museum. A. L. Maltby, Manager.

March 10-15—Paterson, N. J. Paterson Automobile Trade Assn., Fifth Regiment Armory. H. MacGinley, Show Manager.

March 10-15—Syracuse, N. Y. Syracuse Automobile Dealers' Assn. Harry T. Gradner, Manager.

March 10-15 — Omaha, Neb. Fourteenth Annual, Omaha Automobile Trade Assn., Auditorium. Clark G. Powell, Manager.

March 12-18—Peoria, Ill. Passenger cars, 12 to 15; trucks, 17 and 18.

March 15-22 — Boston, Mass. Boston Automobile Dealers' Assn. Passenger cars only. Chester I. Campbell, Manager.

March 15-22—Harrisburg, Pa. Harrisburg Motor Dealers' Assn., Overland Warehouse. J. Clyde Myton, Manager.

March 17 - 22 — Great Falls, Mont. Montana Automobile Distributors' Assn.

March 17-22—Philadelphia, Pa. Motor Truck Assn., Commercial Museum.

March 19-22—St. Joseph, Mo. St. Joseph Automobile Show Assn., Auditorium. John Albus, Manager.

March 19-22—Norfolk, Neb. Norfolk Automobile Show Assn.

March 22-29—Pittsburgh Automobile Dealers' Assn. of Pittsburgh. John J. Bell, Manager.

March 22-29—Passenger Cars. April 1-5—Trucks, Brooklyn. Brooklyn Motor Vehicle Dealers' Assn. I. C. Kirkman, Manager.

March 24-29—New Orleans, La. Henry B. Marks, Manager.

March 24-29—Greenfield, Mass. Greenfield Automobile Dealers' Assn., State Armory. James J. Callahan (Pittsfield) Manager.

March 24-29—Utica, N. Y. Utica Motor Dealers' Assn.

March 26-29—Watertown, N. Y. Tenth Annual, State Armory, Automobile Dealers, Inc. Arthur E. Sherwood, Manager.

Third week March—Trenton, N. J. Trenton Auto Trade Assn. John L. Brock. Manager.

April 5-12 — Bridgeton, N. J. Fourth Annual, Automobile Dealers' Assn.

April 5-12—Montreal, Can.—National Motor Show of Eastern Canada, Victoria Rink T. C. Kirby, Manager.

April 13-19—Bristol, Tenn. Cars trucks, tractors, airplanes and accessories. Bristol Chamber of Commerce.

Not decided—Bridgeport, Conn Auspices of City Battalion B. B. Steiber, Manager.

Not decided—Indianapolis, Ind Indianapolis Auto Trade Assn. John B. Orman. Manager.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

TRACTOR SHOWS

Feb. 15-22—Minneapolis, Minn.

Feb. 18-22—Wichita, Kan. Annual Mid-west Tractor and Thresher Show. Wichita Tractor and Threshing Club. Forum.

Feb. 24-March 1—Kansas City. Mo. Fourth Annual Tractor Show. Sweeney Building, Kansas City Tractor Club. Guy H. Hall, Sec.

RACES

March 15—Santa Monica, Cal Speedway.

May 17—Uniontown, Pa., probably 112½ miles.

July 5—Cincinnati, O., Speedway.

CONVENTIONS

Feb. 25-28—New York. Sixteenth Annual Convention. American Road Builders' Assn.

Feb. 25-28 — Ninth American Good Roads Congress and 16th Annual Convention of the American Road Builders' Assn. Hotel McAlpin, New York.

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago — National Foreign Trade Council Sixth National Foreign Trade Convention. Congress Hotel.

Capt. E. N. Purvis, Quartermaster Corps; First Lieut. E. A. Mechling, Quartermaster Corps; Mr. Ray Mackey.

Chicago, Ill., 1819 West Thirty-ninth Street—Col. Roy B. Harper, Cavalry; Capt. J. M. Griffith, Quartermaster Corps; Capt. John A. Bussian, Quartermaster Corps; Mr. Frederick C. Hack; Maj. E. J. Zimmerman, Quartermaster Corps; Maj. E. H. Caswell, Quartermaster Corps; Maj. George F. Mayer, Quartermaster Corps; Capt. J. C. Shugert, Quartermaster Corps; Capt. H. M. Rodgers, Quartermaster Corps; Capt. E. A. Hey, Quartermaster Corps; Capt. Edward Rosing, Quartermaster Corps; Capt. George H. Bussman, Quartermaster Corps.

San Francisco, Cal., Fort Mason—Maj. Gen. C. A. Devol, United States Army; Col. Charles A. Varnum, United States Army, retired; Mr. Clay Miller.

San Francisco, Cal.—Mr. William Thomas; Mr. Milton H. Esbert.

Baltimore, Md.—Maj. D. W. O'Neil; Maj. J. L. Beatie; Capt. S. T. Griffith.

New York, N. Y.—Lieut. Col. Benjamin L. Jacobson, Maj. Joseph E. Lee, Quartermaster Corps; Mr. William R. Collins; Mr. John H. Love; Mr. Henry Ittleson; Second Lieut. William C. Lovett, Quartermaster Corps.

Washington, D. C., Seventeenth and F Streets N.W.—Capt. W. J. Schaefer, Quartermaster Corps; Maj. H. A. Barnard, Quartermaster Corps; Capt. C. F. Young, Quartermaster Corps; Capt. R. A. Burbank, Quartermaster Corps; Mr. Ben J. Miller.

Signal Corps.

Board of Contract Review—Lieut. Col. R. H. Morse, Maj. R. A. Klock, Maj. J. R. Whitehead, Capt. Lawrence Thompson, Capt. S. M. Conant, Capt. W. S. Kelly, Capt. Milhau.

Chemical Warfare Service.

Board of Review—Maj. Gen. W. L. Sibert, Col. N. T. Bogart, Maj. C. C. Combs, Capt. William K. Jackson, Capt. H. S. Brown.

Board of Review, Gas Defense, New York City—Col. Besse, Maj. Schult, Capt. Kay, Lieut. Mitchell.

Board of Review, Gas Offense, Edgewood Arsenal—Col. William H. Walker, Maj. E. E. Free, Capt. R. D. Gordon.

Board of Review, Gas Development Division, Cleveland—Col. Dorsey.

Air Service.

Board of Review of the Bureau of Aircraft Production—Lieut. Col. A. C. Downey, Lieut. Col. H. S. Brown, Lieut. Col. F. E. Smith, Capt. F. B. Schnacke, Capt. S. M. Wiley.

Board of Contract Review of Division of Military Aeronautics—Lieut. Col. Harold Bennington, Maj. Edw. Burns, Maj. W. G. Roberts, Capt. Otis Van der Mark, Capt. William G. Dean.

Engineer Corps.

Board of Contract Review—Maj. C. M. Goodrich, Capt. H. L. Beach, Capt. M. B. Keeler, Capt. J. B. Hall, Capt. Grove Ketchum.

Construction Division.

Board of Review—Col. J. N. Willcut, Lieut. Col. J. N. Pease, Lieut. Col. H. F. Durant, Lieut. Col. L. L. Calvert, Maj. H. J. Burke, Maj. C. F. Neff, Maj. L. G. Kelly, Capt. C. N. Foster, Capt. William B. F. Manice, Capt. J. B. Hudgins.

High Tariffs and Prohibitions Hold Industry Back

European Cars Will Benefit American Products—Internationalization of Product Needed—Need for Co-operation and Not Exclusion To-Day

By David Beecroft

NEW YORK, Feb. 25—The decision of France to prohibit the importation of automobiles for one year and the total war prohibition of England being continued indefinitely are about as sensible as our protective duty of 45 and 30 per cent on all automobiles imported into the United States. Imaginary fears and needless protection are at the bottom of the situation in all three countries.

Take the United States first: As the largest producers of automobiles and a country whose production has risen steadily until a year ago, instead of practically shutting out all foreign-built cars by our high tariff wall we would be better off to have a real liberal sprinkling of foreign-built cars sold throughout the country, yes some in each of the forty-eight states. A reduced tariff would make this possible.

The reason is not far to seek: Europe has been compelled to build with regard to the conditions of her people and surrounding conditions. The high price of fuel has given rise to the smaller engine of high efficiency. The individualistic nature of her people has led to a luxury and comfort in body design that is not known in America. The national British characteristic for reliability and roadability has resulted in a class of workmanship that is very desirable. The limited pre-war incomes of many car owners made it necessary to have vehicles of relatively low maintenance cost. Low maintenance cost has resulted in certain character of accessibility that can be imitated to advantage.

France has operated along similar lines. So has Italy. For years we have recognized the development that France and England and Italy and Germany have achieved in racing automobiles. We have liberally copied European designs in all aspects. Our industry got its foundations in these countries.

Ten or 20,000 automobiles from these countries would be a healthy leaven among the 1,500,000 automobiles our own makers are distributing annually in our forty-eight states. The value of these machines would have an influence on our automobile design. Let them come in and compete with us and if they are better than ours we have the opportunity of making such a discovery rather quickly. If they are superior we should be quick to take advantage of those designs that are responsible for such, just as it was necessary for us in automobile racing to fashion our racing machines very closely after those of Europe and endeavor to improve on the European design wherever possible or keep out of racing.

We have a much better opportunity of discovering the good qualities of these foreign machines by having a healthy supply of them in our midst, where

we can get accurate records on them on all our road conditions, than if we shut them out of our country and only get a line on them from their performances in South American countries, Africa, Australia, India, Japan, or other parts of the world. Let us meet them at home and learn of them here.

Question of Low Clearance

Some have argued that the European car cannot be used on our roads excepting in a few of our larger cities. If this is the case we have little reason to fear, but as a matter of fact, there are two sides to this argument. We argue that the low-clearance European automobile cannot possibly operate on our roads in the grain belt. The European engineers say that their clearance is such that they can operate successfully and that to have a low body on an automobile does not necessarily mean reducing the necessary clearance. We should find this out in America rather than in Chili.

European designers and manufacturers have no little fun at our expense in the matter of body design. They put it aptly when they remark: "You sit in a European car but on an American car." There is more truth in the remark than many of us wish to admit. We learned a lot from European racing cars that came to this country. The development of the Liberty aviation engine was to quite an extent due to the European racing cars that came to America in the two or three years previous to the war.

Had we shut such racing vehicles out we would have paid a heavy penalty for the prohibition. Let us be careful that we do not shut out a lot of good things in the European automobiles which while not selling anything like so cheap as ours have a lot of merit in them, and perhaps the best step in progress might be abstracting some of the good qualities from these cars, reshaping them to American production and factory methods and thus going one step farther in our great accomplishment of making a better low-priced automobile. We have much to learn in body design and Europe can teach us a whole lot.

Does Not Need Tariff Wall

American automobile makers do not need the 45 and 30 per cent tariff wall to protect them to-day. It seems gravely possible that this tariff wall has shut out more good in the way of quicker progress than it has afforded good through its scheme of protecting our makers from foreign invasion. It was necessary in early days when we could scarcely walk.

We had the high tariff walls because of cheaper European labor, but the war has altered labor costs and while we still lead in high-priced labor the difference is not so great as it was in 1914. What we lose in labor costs we more than make up in production methods and production machinery.

Looking now at the case of the British and the French as well as the Italians: The French and British have asked for complete protection by way of total prohibition in order, as they put it, to get turned around after the war. This is true with regard to many of the factories and so the rule must be for the benefit of all. But in these countries they are to-day shutting out automobiles that their people want, namely, lower-priced machines than any of the makers in these countries are preparing to produce. This does not look so much like protection for the benefit of any class of maker so much as a failure to recognize that in England and France there are tens of thousands of people who want very cheap automobiles, but which are not made for them in their own country, and which the makers are not taking definite steps to produce. In both of these countries the automobile manufacturer built for the classes more than for the masses, and yet to-day, after the war, we fail to find much greater recognition of the farmer who wants the utility car. The European post-war program by price is still for the classes, the people of wealth, rather than for the masses. Total prohibition does not remedy such a situation.

European Plants in Good Condition

The majority of these European factories are in a much better position to-day than American factories. This is particularly true speaking financially. They have been on war work for 4 years and in some cases longer. After making great factory expansion they had 2 and 3 years to make good war profits out of the expanded plants, whereas those American makers who made heavy expansion enjoyed the fruits of such for a very brief time. We have some makers who did not have 6 months production in their new or expanded plants. They got the plants but not the profits out of them.

It is quite common with the expanded French factories to write them off at the value of 1 franc, 20 cents, in the financial report of the company. This is true with many of them. It also applies to some of the British and Italian factories. These factories cannot ask for total protection through total prohibition for financial reasons, but in most cases because of lack of preparation for post-war work, and yet they do not in scarcely a case contemplate that low-priced production which they are shutting out. Their present prohibitions are preventing certain masses of their peoples from purchasing vehicles that the makers in these countries are rarely if ever planning to provide. Again the shutting out process does not appeal as a specially rational one. It is about on a par with the wall on the west side of the Atlantic.

Lock Out More Than We Lock In

Some steps in a general re-adjustment might be made to the advantage of all. There are factors in our cars that European makers want and there are factors in European automobiles that our makers are in need of. An interchange is desirable. A fair exchange never has been robbery, nor will it be in this instance. The more we apply the total-prohibition-of-cars order to merchandising the further off do we keep the exchange of ideas. The more we apply total prohibition the more we shut out automo-

biles, but also the more we shut out engineering and manufacturing experience. It becomes an international application of that threadbare epigram on the locked-door of the engineering department, namely, "we lock more out than we lock in."

The automobile as well as the motor truck, the airplane, the farm tractor, the motorcycle and the motor boat are international in their usefulness. Our automobiles from a Detroit factory go to forty countries of the world, they go to every country. The automobiles from other countries will go to every land on the globe. There are only five or six countries that have to supply all of the other countries with their automotive apparatus. The world is large and there is abundance of money in it to buy twice as many cars as are sold to-day or any day, month or year up to the present.

The major objective is to make it easier for the world to buy, operate and maintain automotive apparatus. It is not nearly so easy to-day as it should be and if manufacturers of different countries got closer together and knew more about each others products and talked the industry more it would be better for all.

An Example

Take a case in question: European makers are all installing electric starting and lighting equipment. This means a battery for each car. England has twenty-three different battery makers, nearly all of whom are working to any standard the automobile maker insists upon. France has its quota of makers and so has Italy. Some of the automobile companies are manufacturing their own batteries. Add to this the numerous battery models in America and then for a few minutes transplant yourself to Cape Town, or Sydney, or Buenos Aires, and imagine you are a dealer handling an English, a French, an Italian and an American car. Perhaps you have two or three different models of each make with a different shape of battery for each. To make it easy to operate all of the different models you sell you must carry a liberal stock of all these battery sizes on hand and in doing so you are tying up capital, and in a word you are paying the bill for this lack of international standardization, but with true business characteristic you pass it on to the consumer and he eventually pays the price. It is not so easy for that consumer to own and operate an automobile as it should be.

The Question of Tread

The situation might be analyzed further with regard to tires, spark plugs, headlights, electric bulbs, tail lights, etc.

A further case in question is that of tread. What walls of sales resistance we would be erecting if Italy undertook to merchandise export models with 60-inch treads in several countries that might insist on such. How much better for all concerned that Italy should market cars with 56 or 57-inch treads. With this there is no wall of sales resistance built up that American makers have to wage constant merchandising attacks against and vice versa.

What walls of sales resistance would be immediately knocked down if the rules of the road were internationalized just as the rules of navigation on the sea are internationalized and just as the rules of navigation in the air are to be internationalized! When different rules of the roads first sprung into use the vehicles then used could be driven on either side of the road without any changes being made, but when the motor car arrived with its steering gear it was necessary to mount it on one side for England and on another side for America. If all countries agreed on the laws of using the road a wall of sales resistance would be quite eliminated and manufacturing costs would be reduced as well as sales costs. The tail light could be then put on one side for all vehicles. It would be easier for more people to own automobiles.

Prohibition Separates U. S. and Great Britain

When the different countries in the Commonwealth of Australia built their railroad systems they built them selfishly for their own country only. New South Wales built for herself only, and Queensland and Victoria and the other political divisions did likewise. Each used a different tread so that one locomotive cannot travel over the lines in any other country. It was a beautiful scheme of exclusion and prohibition that is to-day costing the commonwealth millions annually and will continue to do so until the treads are standardized. The longer the day of transition to a standard is put off the more expensive will be the task.

The same is true of automotive apparatus. The more Great Britain shuts herself up unto herself; the more France builds walls around herself; the more Italy does; and the more the United States does, the more are all of these great producers keeping apart at the very time when they should be getting closer together. Instead of prohibition, greater interchange of ideas is needed.

America Sold to High-Gear Cars

If we are afraid to let French, British and Italian cars into our midst and they have the same attitude toward us, it is a case of all four having about the same imaginary fears. If the European car is not suited for our agricultural areas because of low clearance, lack of horsepower, and lack of high-gear performance, then it is not necessary to shut it out, because those who attempt to sell such vehicles will find out that they cannot be sold, if all these charges are true. On the other hand if we find that their lower and more comfortable automobiles are suitable for our highways then we should be quick to adopt such features and incorporate them into our designs and re-shape them for our conceptions of production. To-day America is sold to the high-gear car for every hill. Europe changes gears and claims many advantages for it.

A goodly supply of European cars might serve to convince us that some modification might be highly desirable and would not be followed by great sales resistance.

Europe is not going to be able to permanently

(Continued on page 506)

Experimental Design and Testing of Airplane Ribs

Testing Machine Used in Determining Wing Rib for Glenn L. Martin Company's Twin Engined Bomber Distributes Load as in Flight

By George B. Fuller and Lessiter Milburn

THE function of the rib in an airplane is to carry the load with the least possible distortion and with the proper factor of safety.

Inasmuch as no mathematical solution is readily applied to the average airplane rib, a method of experimental design was adopted to produce a rib which should meet the requirements with the least possible weight, and at the same time utilize the least possible time, labor and material expense in production.

The airplane rib is, at best, a very light and non-rigid member. The rib shown in Fig. 2 has a 94-in. chord, is ½ in. wide, weighs 11½ oz. and carries and ultimate load of not less than 555 lb. This rib was the final selection from the results of a series of tests made upon ribs of various types which were designed by approximate mathematical methods.

The conditions demanded of a rib-testing machine follow:

1—A rib-testing machine should hold the rib and apply the load in the same manner as the air load when the rib is in the wing.

2—The distribution of the load along the chord must not vary from the predetermined load grading when the rib deflects as the load is applied.

3—The machine should be so arranged that the load may be varied from zero to the breaking load, and an accurate means of measuring the load at any point must be provided.

4—An accurate means of measuring the distortion of the rib under load should be provided.

As the load on the rib varies continually with the varying angle of incidence of the wing, the most severe case was chosen. The supports of the rib, also, are not all the same. At or near the drift struts the ribs may be said to have a fixed or rigid support, while near the center of the bay, the rib supports may be considered as not being fixed, due to the spring of the beam. In these tests a non-rigid support was used

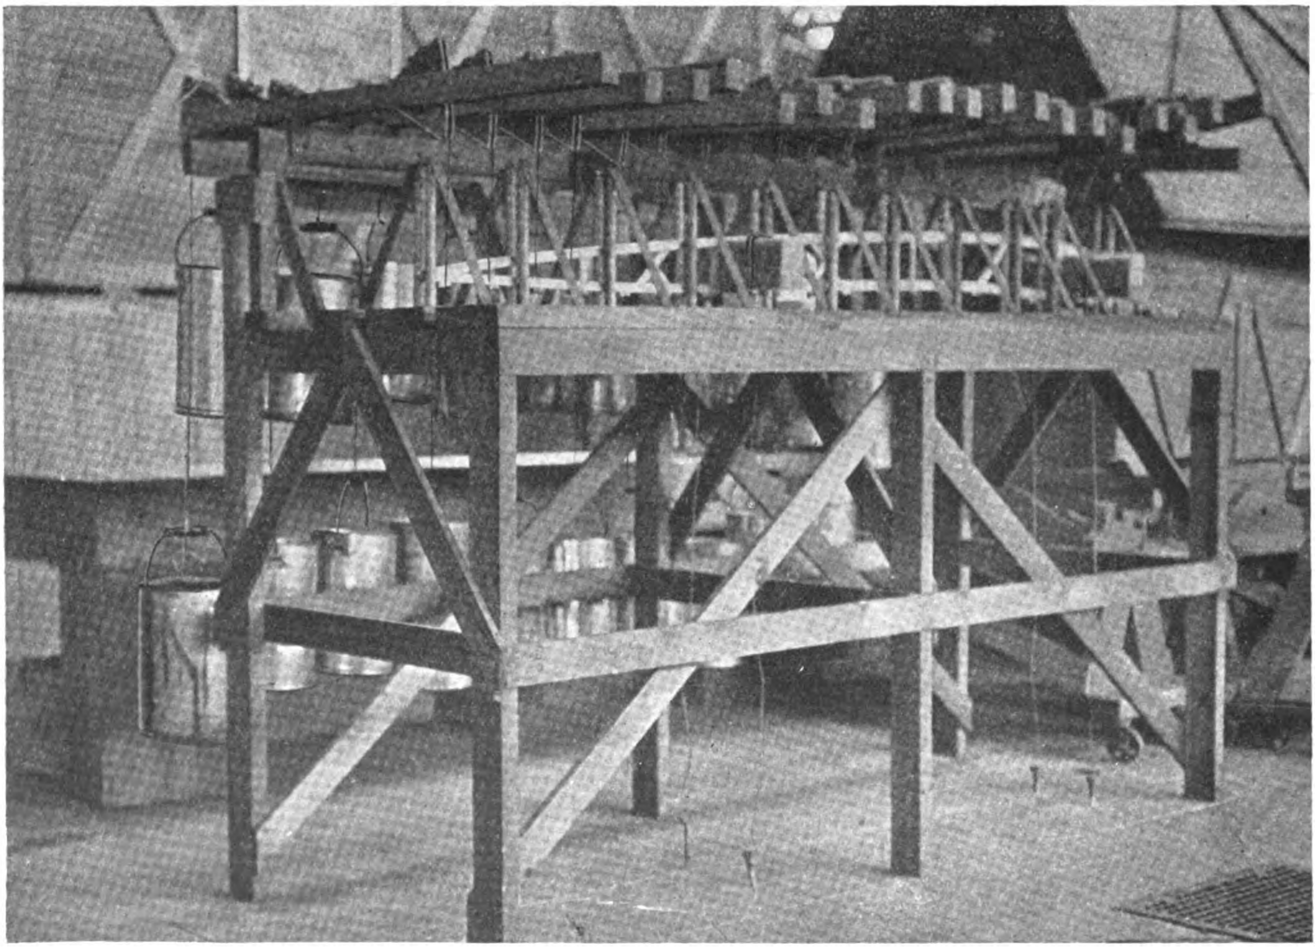

Fig. 1—General view of the testing machine with the rib mounted in place for test

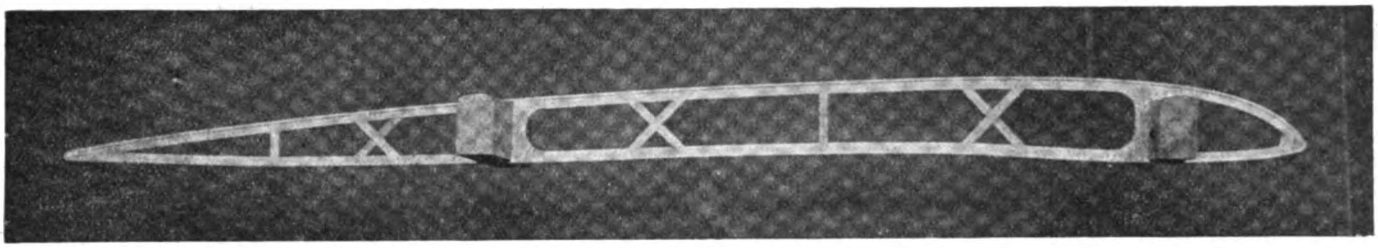

Fig. 2—The final rib selected from the results of the tests has a 94-in. chord, weighs 11½ ounces and carries an ultimate load of not less than 555 lb.

after the first five tests, to give the most severe condition.

Bearing in mind the above conditions of loading and methods of fastening, there were some five methods of applying the load to be considered, as follows:

1—A system of equalizing levers, linked together, which would distribute the load over the rib, the lengths of the levers being proportioned to give proper loads at the points required.

2—A system of loading the rib, through rubber bands of varying strength, to agree with the load-grading curve.

3—A system of springs used in the same manner as the rubber bands.

4—A system of hydraulic cylinders, the area of each being proportional to the load, as taken from the load-grading curve at the particular point, all having the same pressure.

5—A system of levers resting on knife edges, each lever being independent of any other and having its own load applied in a pail, or the like.

After a number of sketches had been made and the points of advantage and disadvantage of each of the above methods fully considered, the fifth or last method was adopted and used in all the following tests.

Description of the Machine Used

Several views of the machine are shown, in Figs. 1, 3, 4 and 5. It was constructed of wood, with a platform at about the height of a man's arm, on which the rib was to be placed. Guides of ¾-in. pipe were secured to the platform to maintain the rib in a vertical position, as shown in Fig. 4. At the rear of the platform knife edges were mounted on a horizontal beam. Over these knife edges twenty ash levers were set, each having a metal plate to take the knife edge, Fig. 3. Both ends of these levers were cut in the form of an arc, having the center at the knife edge, so that the lever ratio was always the same. At the rear end of each lever a pail was attached and the front ends were connected to the stirrups by wires, Fig. 4. The lower end of the wire was slipped through the stirrup, bent up and secured with a small washer so that the stirrups could be readily fastened to the wires. The distance from one stirrup to the next was 4.7 in. Each lever was counterbalanced with a weight, so that when the pails were empty the lever rested evenly on the knife edge.

To reproduce the condition of non-rigid support of the ribs mentioned above, the test ribs were made up on dummy spars as shown in Fig. 2. Two U-bolts were passed over each spar and connected to the floor by steel cables, leaving the spars free to move without respect to each other.

Method of Loading

The load may be applied by putting either water or sand in the pails. When the machine was designed it was intended that a water load be used. A tank was to be placed over the loading pails with twenty lines of hose, one leading to each pail. In the end of each hose a nozzle was placed having an exact diameter and calibrated for various heads. The diameters were such that the water would flow into the pails according to the ratio established from the load grading curve. The flow of water was to be controlled by a gate valve operating on all the lines of hose at the same time.

On account of delay in securing apparatus for water loading, sand loading was substituted. A small measure was made for each of the load pails, and the capacity of each cup was so proportioned that when one round of cups of sand had been poured into the pails the pull on the stirrup was in agreement with the load-grading curve chosen.

In order that the size of pail used would not be too large, it was necessary to adopt three ratios of leverage for the levers. Beginning with the leading edge of the rib, the first six levers were made with a ratio such that the pull on the stirrup was three times the load in the pail. The next seven levers had a ratio of two to one, and the last seven, one to one. The three sets of knife edges may be noticed in Fig. 3.

Operation of the Machine

The rib being assembled and secured to the dummy spars ready for test, twenty small grooved blocks were tacked along the lower edge as seats for the stirrups, to prevent crushing of the cap-strip and to simulate the sewing of the fabric to the rib, as done in the wing. The rib was placed on the platform of the machine, between the guides, and the stirrups

were attached to it. The stirrups were then attached to the levers, and the balance of the levers checked as a precaution. The four U-bolts were put on and connected to the steel cables leading to the floor, the lengths of the cables being adjusted so that all four would become taut at about the same time. The guides were fastened so that the rib would just slide easily between them. The purpose of these guides was to approximate the condition in the wing, where the ribs are cross-tied with tape and sewed through the wing every 2 or 3 in. with a stout linen cord to prevent them from twisting out of the vertical.

One round of cups, or measures, of sand of a fine, dry grade was placed in the loading pails to take up all slack in the wires, cables and stirrups. The total load on the rib at the end of one round was 41 lb., distributed in this case according to the load-grading curve shown in Fig. 6. A steel scale was placed at the center of the rib and a reading point selected and marked on the rib-web.

A second round of cups was then poured into the pails, and a reading taken on the scale, for the purpose of comparing the relative rigidity of various ribs. The loading was continued by rounds, until failure occurred, the contour, and weak points of the rib being carefully observed meanwhile, together with the readings for rigidity. At stated points during the loading, as, for instance, at normal load, at two, four, six, or eight times normal load, photographs were taken of the rib. By comparing tracings, made from these photographs, with the natural, free outline of the rib, an accurate measure of the rib contour under stated loads was obtained.

When the rib failed, the point, and probable cause of failure were noted. Fig. 5 shows a typical fracture.

After failure, the amount of sand in each load pail was carefully determined, and the weight recorded with the pail number. From these weights, the total load on the rib was checked, and also the distribution of the load by means of a curve, plotted with the loading points as abscissae, and the pail weights as ordinates. This curve will have the same form as the load-grading curve, if the test has been properly carried out.

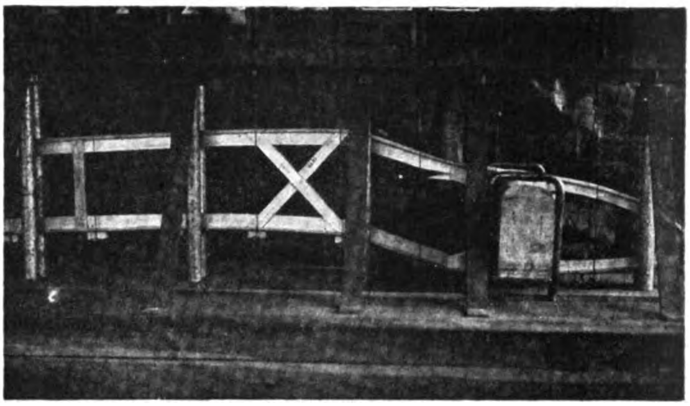

Fig. 5—Failure of rib showing the effect of spiral and diagonal grain spruce

The time required for test was three to five minutes, which was the disadvantage of using sand, instead of water. The water load can be applied in any time, down to about 15 seconds, by enlarging the orifices in the nozzles, or increasing the water-head.

After test, the rib was removed from the machine, detached from the dummy beams, and weighed in fractions of an ounce.

Progress in Design

The method of experimental design is at best a "cut and try method." The first five ribs were designed by approximate mathematical methods. All the others were an evolution from them by making a study of the action of the rib during the test to destruction, and either making the weak section stronger and the strong sections lighter, or by redesigning the various details of the rib, which failed, or showed extra strength, to secure the desired results.

Ten types of ribs were experimented with, nine of which are shown in Fig. 9, the tenth being the well-known Handley-Page type of rib. Thirty-four ribs were made and tested before a satisfactory rib was produced. Since production has been in progress, a number of tests have been made which are not shown in the table.

All the ribs tested were loaded according to the air loading shown in Fig. 6. This chart also shows an average typical loading, the result of a test, and gives a good idea of the small error in the loading by this method of testing. While this error may seem to be large at some stations along the chord of the rib, it is known by actual weight and no interpolation is necessary to find the load at any station.

The following table gives a complete analysis of this difference between the sand loading and the air load curve selected. The average difference over the stations is

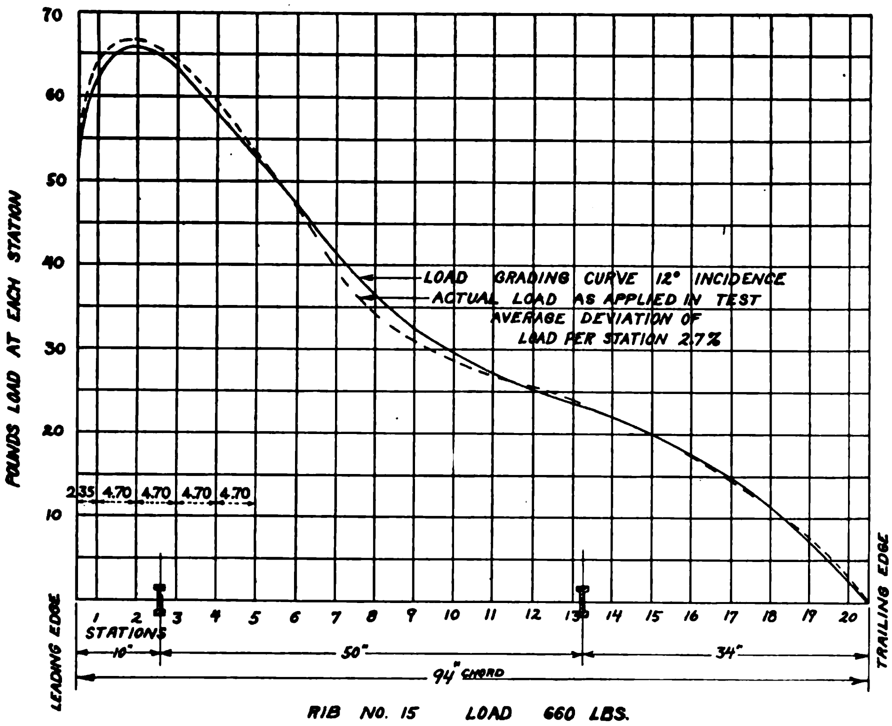

Fig. 6—Curve showing the distribution of load along the rib

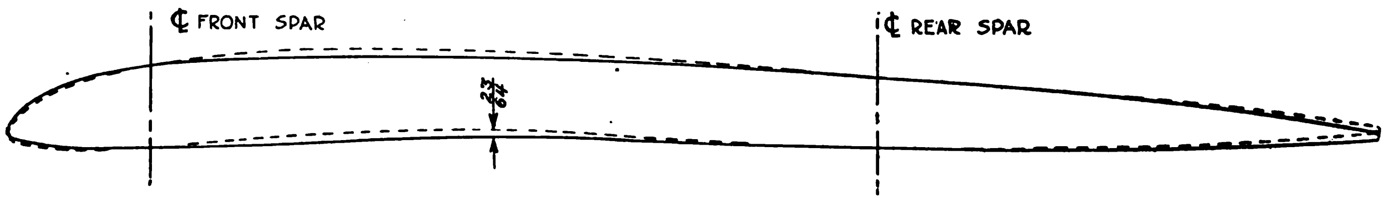

Fig. 7—Rib section to scale obtained by tracing photograph showing total deflection under distributed load

.78 lb. The average difference in per cent is 2.7 and appears largely to be due to the loading at station 20. If we neglect station 20, the average per cent of error is 1.8 per cent instead of 2.7 per cent.

Types of Ribs Tested

The large table on page 458 illustrates the various types of ribs designed and tested, and gives a complete detail of each rib as to material used and the dimensions.

Type "A" was designed along the standard type of rib generally used. It had a 5/32 in. birch veneer web with the grain of the outer ply running horizontal. The cap-strips were 3/16 x ⅝ in. selected spruce.

Type "B" is the same as Type "A," except that reinforcements were put on the web to prevent buckling. Ribs 2 to 8, inclusive, were of this same type and material, 7 and 8 being a little heavier than the others. These ribs also showed a strong tendency to bend in the horizontal portion of the rib at each portal near the vertical portion of the web.

Type "C" is the same general design as Type "B." The web in the center, nose and tail sections being of 3/16 in. thick spruce instead of 5/32 in. veneer. The "X" bracing was put on the web between each portal. In the tests this prevented the shearing of the webs and leads to the next type.

Type "D" is similar to Type "C," except that the portalled web is replaced by the "X" brace of veneer and a thin strip of spruce next to the cap-strip shaped to conform to the curve of the wing section, this strip with the cap-strip forming a "T" section. The cap-strips were reduced from ⅝ x 3/16 in. to 9/16 x 3/16 in. and again to ½ x 3/16 in.; also the web thickness has been reduced from 3/16 to ⅛ in. thick. The shape of the "X" brace will be seen. It was taped and doped to prevent any shearing tendency. Veneer gussets 3/32 in. thick on both sides of the web next to the beams are used to take up part of the bending.

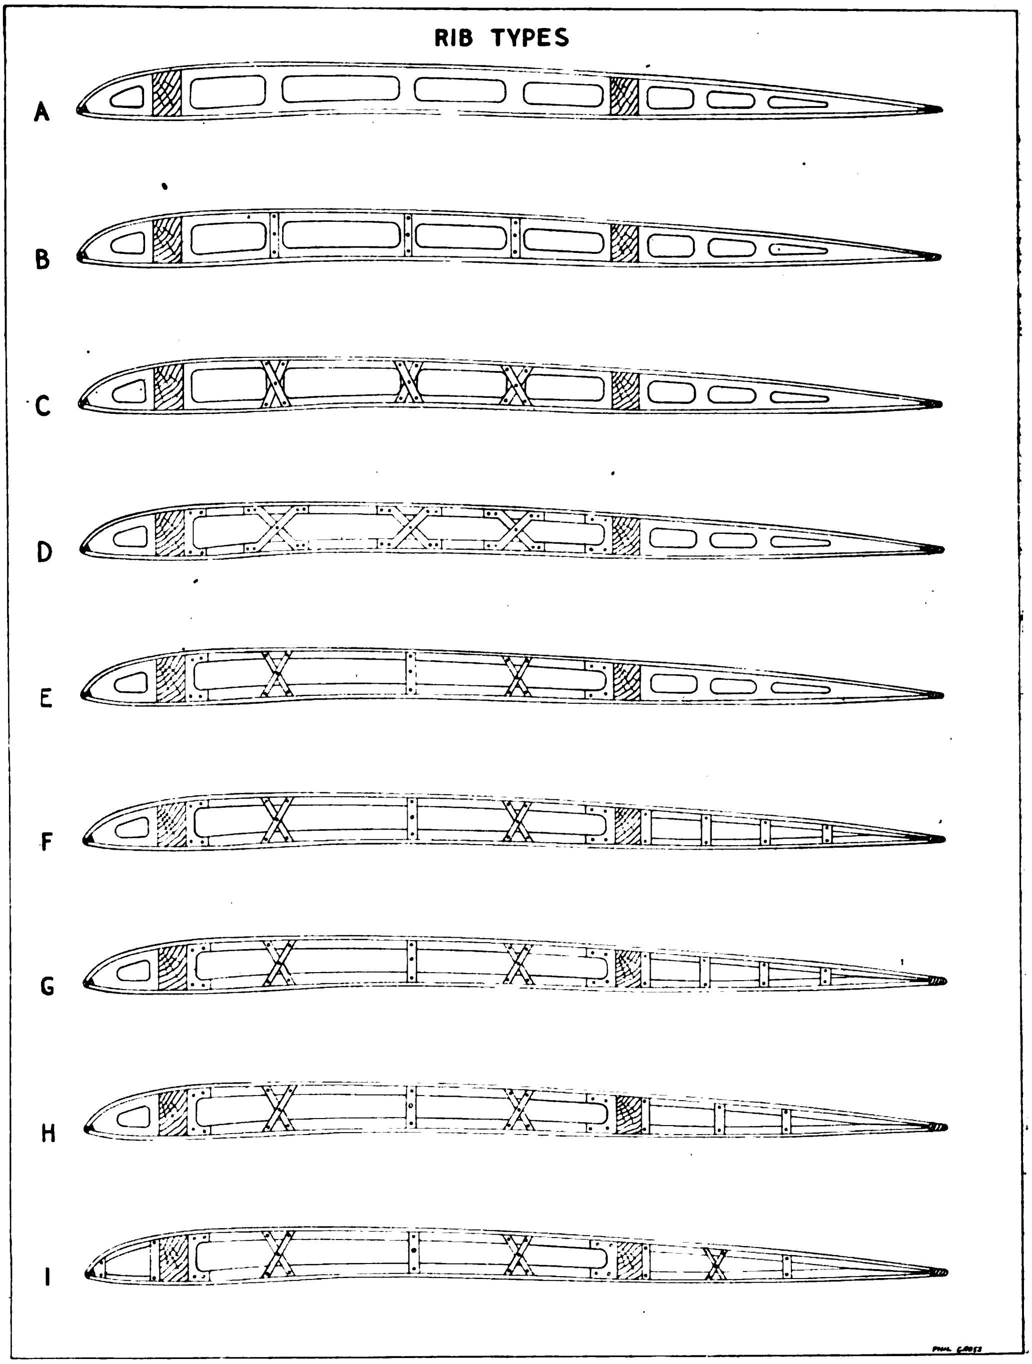

Fig. 9—Various types of ribs tested. The reference letters are those used in the table on page 458

From the table, page 458, it will be noted that the size of the cap-strips is ½ x ⅛ in., and that the central "X" brace was replaced with a vertical brace. This now makes two sets of "X" bracings in the center section. It might be noted here that the "X" bracing and the single vertical bracing are double, one on each side, separated by a block ½ x ½ x ⅛ in.

Type "F" is a marked departure from all previous types, in that the portalled section at the rear of the rear beam is replaced with a built-up section similar to the center section. Vertical grain spruce gussets were substituted for the veneer gussets next to the beams on the central section.

Type "G" is the same as Type "F," except that horizontal grain spruce gussets were used instead of the vertical grain. On trial the spruce gussets proved to be unsatisfactory.

Type "H" has veneer gussets on the central section, but had only two verticals in the tail section and, as in Type "G," the tail section took a marked crescent shape showing the necessity of an "X" brace to take the shear.

Type "I" is similar to Type "H," except that it has one "X" brace in the tail. The section in front of the front beam is built up of strips similar to the center and tail sections. This type of rib is the one used in all the airplanes so far produced by The Glenn L. Martin Co. It is made entirely of spruce, except for the four small gussets, next to the wing spars, which are 3/32 in. veneer.

Only two ribs of the Handley-Page type rib were made and tested. At this time it was decided not to carry the experiments any further, but to use Type "I" rib, as it made a very good production job and was found to be equally strong for normal flight as well as for upside down flying.

Since the table was made, a large number of tests have

(*Continued on page* 489)

Airships Practical for Commercial Use

Valuable for Trans-Oceanic Flight or for Difficult Country—Can Be Supplemented by Airplane for Short Haul Work

"A CONTINENTAL airship service could be run from Lisbon to New York, passengers being taken to Lisbon from Paris, Rome, etc., by airplane."

This is only one of the statements which appear in the report on Airships for Commercial Purposes, issued by the Air Ministry of Great Britain. Official statistics show that only one airship has been lost in England owing to catching fire in the air, although 83,360 hr. have been flown and over 2,500,000 miles covered during the war. In the case referred to the flight was an experimental one with a new type of ship, and the cause has since been ascertained and eliminated.

In a matter-of-fact way the official report of the Air Ministry covers some of the most startling developments in aerial navigation. It is impossible to read through the report without the feeling that we are just on the verge of utilizing the air as a medium of transportation to an extent which was not dreamed of before the war. When thinking of flight, it has become customary with us to think of the heavier than air machine, or airplane, but the airship has been developed to an extent which has not been generally realized, and it appears from a study of the British report that the Air Ministry is well aware of the relative advantages of each and of the particular fields in which each can do its work.

The Relative Advantages of Airships and Airplanes

In view of the different characteristics of airships and airplanes, it appears that the future uses of the two types for commercial purposes will not conflict. The airship is essentially a long-distance weight-carrying craft as compared with the short-distance high-speed airplane. It should be noted, however, that even in the matter of speed the airship of to-day with a speed of 77.6 m.p.h. can be considered slow relatively to the airplane, as she is unquestionably fast in comparison with land and sea methods of transport. In addition to this the airship has the advantage of not being dependent upon her speed through the air for her ability to remain aloft, and is not, therefore, liable to forced descent in case of engine failure, as is the airplane. Quite large repairs to engines, such as the changing of a cylinder, are possible in an airship.

The airship, then, is worthy of consideration for commercial flights over sea or land of a wooded or broken nature, such as to be unsuitable for the landing of airplanes, and on journeys involving non-stop flights of 1000 miles and upward. In addition to this, airships are the most suitable aircraft for the carrying of passengers, where safety, comfort and reliability are essential. An airship can remain aloft while engine repairs are effected; she always remains on an even keel, and there is, therefore, no danger in flying at night or in fogs or clouds, and the great lift permits of much more comfortable accommodation being provided than is possible in an airplane, there being room to move about. In the case of a rigid airship, for example, a walk of 400 or 500 ft. may be taken along the keel. The fact that the envelope is filled with an inflammable gas need not cause any misgivings as to safety, when one remembers the large number of motor vehicles which have been used during the war carrying bags filled with equally inflammable coal-gas at no greater distance from the engine than in the case of the airship.

Airship Stations for Trans-Oceanic Traffic

It appears that for commercial purposes large rigid airship stations should be established at distances of 2000 to 3000 miles apart, mainly for trans-oceanic traffic, while the airplane would be used for bringing passengers and merchandise to these from the neighboring countries. In this way the airplane would compete with the train and the airship with the steamship, over which she would have the advantage of reducing the average time of transit by at least 50 per cent. In addition to this airships would be used for linking up the railways in such places as Central Africa, where the country is difficult both for airplanes and land transport.

It is worthy of note that, though airships are generally considered to be fair-weather craft, up to the end of November there were only nine days in 1918 when no airship flight took place in the British Isles—which are notorious for possessing almost the worst weather conditions of any country in the world. The airship is able to fly on days when fog or low-lying clouds are prevalent, which might be considered unsuitable for airplanes.

Features of Latest German Rigid Airship

In long voyages, advantage could be taken of favorable winds and the routes chosen accordingly. Owing to her long endurance, an airship could afford, should a depression be met with, to fly either over or round it.

The latest German rigid airship has a disposable lift available for crew, fuel, merchandise, etc., of over 38 tons, which gives her a theoretical endurance (if all the available lift be employed in carrying gasoline) of 177.5 hr. (7 days) at a cruising speed of 45 m.p.h.—the maximum speed being 77.6 m.p.h.—during which 8000 miles would be covered. A detailed statement of the "disposable lift" available for freight of each existing type of British airship showing the gasoline consumption is attached. From these figures the freight which can be carried and the time taken over any given route can be readily worked out.

It should be noted that for purposes of short distance pleasure trips from, for example, South Coast towns, it would not be necessary to establish large stations at each town, but the following principle, which has been found most economical and successful during the war, might be adopted. This consists of building a station provided with permanent sheds, quarters, etc., at some convenient center, and forming temporary bases consisting merely of a small cheap portable shed and a few tents or huts at other places, from each of which one or two airships are run; main supplies being drawn from the "parent" station, where all large repairs are effected. In addition to the use of portable sheds at sub-stations, experiments have been carried out in mooring out airships in the open, which have had such a large measure of success as to promise well in the future.

Mooring Out Airships

An airship has been successfully moored out for six weeks in a perfectly open expanse to a specially designed mast. Only two or three men are required to look after the ship, and winds of up to 52 m.p.h. have been ridden out without any damage whatever resulting. There seems little doubt that with this system an airship could live out in the open for many months at a time. Up to the present this method has only been tried with small non-rigid airships, but it is on the point of being tried with rigids, and there seems no reason to expect other than equal success. The possibilities of using floating sheds on water are also being inquired into and appear to be promising.

It should be noted generally that greater reliability as well as decreased cost will undoubtedly be attainable by improvements resulting from careful research and experiment. For example, the use of a mooring mast will very greatly

increase the regularity of any airship service, as the chief difficulty at present consists in taking airships in and out of sheds. If an airship is left permanently ready at a mooring mast in the open it will be possible to fly in any wind up to the speed of the ship. In the same way improvements in the fabric for non-rigid envelopes and other covers of rigid airships will result in decrease in running costs by reducing the hydrogen consumption, and generally lengthening the life of the ship.

Similarly, a system of recovering water-ballast during flight would obviate waste of hydrogen by preventing the ship becoming "light," owing to the consumption of fuel during a long voyage. It will be understood that as an airship becomes light she tends to rise, which causes the hydrogen to expand, so that it must be allowed to escape through the automatic valves, or the gas-bags would be burst by the internal pressure. This tendency to rise must be counteracted by taking in weight to counterbalance that lost in the fuel consumed.

It may be of interest to note that nine airship stations of various sizes will in all probability shortly cease to be in use by the Admiralty. These will, therefore, become available for commercial purposes, though the greater part of the ground is occupied under the Defence af the Realm Act. In addition a certain number of S. S. Zero airships and coastal star airships will become available for disposal.

Comparison of Rigid Airships and Planes

During the last 4 yr. sufficient experience has been obtained in the construction and use of rigid airships to enable future developments to be forecasted with some assurance of accuracy; and it is, therefore, possible to consider the lines along which progress should be sought, and the performances which, within the next few years, can be obtained from rigid airships. In view of the widely-held opinion that the development of the large airplane will ultimately kill the large airship, it is necessary to institute a comparison between the future possibilities of both types. The result shows that in each case certain inherent qualities govern progress, and that these qualities, being widely different, will cause the two types to cover different fields of utility. It appears also that, whereas increase in size of airplanes brings many difficulties in its train with no compensating improvement in efficiency, increase in size of airships results in a reduction of the difficulties experienced at present, and gives improved efficiency, thereby opening up future possibilities of extraordinary value.

The development of rigid airships has been even more rapid than that of airplanes. In 1914 the average endurance of a German rigid at cruising speed was under one day, and the maximum full speed about 50 m.p.h. In 1918 with the German L.70 class, 2,195,000 cu. ft. capacity, the endurance at 45 m.p.h. has risen to 177.5 hr. (7.4 days) and the maximum full speed to 77 m.p.h. The ceiling has correspondingly increased from 6000 ft. to 23,000 ft. The British R.38 class (2,720,000 cu. ft. capacity) has an estimated cruising endurance at 45 m.p.h. of 211 hr. (8.8 days), 34 hr. greater than the German L.70 class. It is a matter of some difficulty to make a fair and at the same time simple comparison between the two types of transport possessing widely different qualities.

Comparison of Rigids

The figures for rigids are comparatively simple, as they are few in number and all of approximately the same class, compared to the many different classes of H/A machines which have been developed for various purposes. The Avro has been taken as the best all-round machine actually in use in August, 1914; large machines such as the Sikorski, the Caproni and the Graham-White five-seater were then only in the experimental stage, and besides did not possess the all-round efficiency of the Avro. The D.H.10a has likewise been taken as the best all-round machine in August, 1918. Although the two-engined Handley-Page and Caproni have greater endurance and weight-carrying capacity, their all-round efficiency appears inferior to the D.H.10a. The Handley-Page V gives promise of having a slightly better performance than the D.H.10a, but this machine is still in the experimental stage and reliable performance figures are not available.

Tables 1 and 2 give the progress in L/A and H/A since 1914. Table 3 shows the difference in performance between corresponding L/A and H/A craft of 1918.

IMPROVEMENT IN SHIPS AND PLANES

TABLE 1. L/A.

It will be seen that at the present time the largest rigids in commission have over 10 times the total lift of the corresponding H/A, and that the disposal lift is about 25 times greater. The proportion of useful lift compared to gross lift is much higher in airships than in airplanes. An approximate figure for an airplane of average engine power is one-third, while in a rigid the useful lift available for fuel, crew, passengers, freight, etc., is well over one-half. In the case of L.70 the figure is 58.3 per cent, although this ship is the most heavily-engined and fastest airship yet built. It cannot be too strongly emphasized that many of the advantages apparently possessed by H/A at the present time result from their relatively small lift. Thus, by airplane of 60 tons total lift, if found to be possible at all, would certainly be very much less convenient to land and handle on the ground than airplanes of existing sizes, and would require overall dimensions about twice those of the largest existing machines.

It is important to note that in H/A there is no automatic improvement in efficiency resulting from greater dimensions. In L/A, on the other hand, such an automatic improvement

takes place to a very marked degree. The reason for this difference is as follows: In similar H/A machines of different dimensions, the total lift, air resistance, and b.h.p.—other things being equal—all vary nearly as the plane areas, i. e., as the square of the liner dimensions.

It follows that the ratio $\dfrac{\text{weight of machinery}}{\text{total lift}}$ does not vary much with size of machine. The ratio $\dfrac{\text{weight of structure}}{\text{total lift}}$ tends to increase with size of machine. Unit area of wing surface can only exert a definite lifting effect, and as the machine increases in size it is necessary to increase proportionally the weight of each preceding unit area of wing surface to make the machine proportionally strong. A point is finally reached where every additional unit of wing surface results in as much increased weight as its lifting effect, so that any further increase in size will involve a definite falling off in the total lifting capacity of the machine. A further small increase in size can be effected by increasing the number of planes; but, owing to the inefficiency of middle plane surfaces, due to the blanketing effect of the top and bottom planes, the resulting gain in endurance will not be large, and it will only be effected at the price of a loss in efficiency.

The theoretical property of structure may, to a certain extent, be modified by the material used. Thus, in airplanes, there is a certain size of machine which can be built most economically of wood. Any machine of smaller or larger size entails a certain proportion of uneconomical weight, due to the inherent qualities of the material. This question of material applies equally to rigids; thus, for ships of 2,000,000 to 4,000,000 cu. ft. capacity, duralumin is the most suitable material for hull structure, while for ships of 8,000,000 to 10,000,000 cu. ft. capacity a saving in weight can be effected by the use of steel. In H/A machines, therefore, all round efficiency, as measured by the ratio of $\dfrac{\text{disposable lift}}{\text{total lift}}$ tends to decrease with greater dimensions. Greater efficiency will, therefore, not result from increase in size, but, on the contrary, great increase in size will not be attainable until greater efficiency has been first obtained by progress in design and materials. In other words, increase in size in H/A craft will be the result and not the cause of increased efficiency.

Benefits from Increase in Size of Airships

In L/A the total lift varies as the cube of the linear dimensions, while the air resistance and b.h.p.—other things being equal—vary as the square of the linear dimensions. Hence the ratio $\dfrac{\text{weight of machinery}}{\text{total lift}}$ decreases automatically.

The proportion of useful lift compared to gross lift is much higher in airships than in airplanes. An approximate figure for an airplane of average engine power is 33 per cent, while in a rigid the useful lift available for fuel, crew, passengers, freight, etc., is well over 50 per cent.

It is concluded that in H/A increase in size without loss in efficiency must result from, and be limited by, the extent of improvement in design, etc. The tendency will, therefore, be to confine airplanes to moderate dimensions, except where large size is rendered necessary by the need of reducing the number of units employed upon a particular service. or by other causes, such as where long-distance non-stop flights are necessary. The outstanding characteristics of H/A will, therefore, remain as at present: high speed, handiness, moderate lift, independence of all weather conditions except the worst. As regards L/A, the functions now performed by the smaller airships will be usurped more and more by H/A. Airships may be expected to develop in the direction of increased size to a limit which is not yet in view. The outstanding characteristics of L/A will be reasonably high speed, very long endurance, great weight-carrying capacity for freight, stores, passengers, etc.

The practical range of all types of aircraft carrying mails, passengers, or merchandise, will be small compared with their maximum range given in these notes, which is calculated for calm air, and assumes, besides, that all the disposable lift (useful load), aside from crew, food, emergency water ballast, etc., is available for fuel. For transport purposes, allowance must be made for the commercial load and additional fuel over and above that actually required for the given flight, which must always be carried in case unfavorable weather is encountered. Actually, the practical range will not be much more than one-fourth of the maximum range.

Summarising, therefore, it would appear that the line of policy to be adopted is to develop the airplane for transport over distances under, say, 500-800 miles, and the rigid airship for trans-oceanic and possibly trans-continental flights of this length.

Large Airships

To obtain a reasonable performance with a small ship, every effort has to be made to save weight, and complicated built up girders must be used owing to their property of forming a light and strong joint. In a large ship, owing to the increase in efficiency with size, it would be possible to sacrifice a certain amount of lightness in construction for the sake of simplicity in design. With increase in size, steel could be used with advantage in place of duralumin, and a great saving in cost effected thereby. With increase in size, too, it should be possible to produce a rigid of so much more rugged construction that it might even be erected in some form of roofless dock, remain either moored out or in flight while in commission and only return to dock for a complete refit, thus saving much of the expense of housing stations. Just as with H/A craft, where airplanes have gradually increased in size, checked and modified in each successive stage by the results obtained under service conditions; so the construction of the really large rigid must be approached systematically, in successive stages, checked and modified at each stage by practical results.

Bad weather will not appreciably endanger a rigid in flight, and its chief operational handicap has so far been the probability that it will sooner or later be caught out in a high wind lasting for a longer period than the endurance of the ship, so that the ship would then have to attempt to land before the wind dropped and would probably be wrecked. If the meteorological reports for previous years are examined it will be seen that even under unfavorable conditions it will be possible for a ship with a three weeks' endurance to leave the shed during any temporary lull in the wind, carry out a fortnight's flight, and calculate on being able to return and land during another lull in the ensuing week. Should the large ship meet a storm, she will be able to go round or over it, and could afford to wait in the air for fine weather in which to land. Thus, if the endurance of a rigid is increased to a sufficient extent, it will be possible to carry out flights with a regularity comparable to that maintained by surface craft. The range, practically speaking, is almost unlimited, and the weight carrying capacity large. A 10,000,000 cu. ft. capacity rigid will have a disposable lift of over 200 tons, which is available for gasoline, ballast, crew, passengers, freight, in varying proportions as desirable. The uses to which such an airship could be put are clearly of great importance. Further, there is no other type of vessel which could as efficiently undertake them.

With a rigid of about 10,000,000 cu. ft. capacity, and endurance of approximately 3 weeks at 40 to 45 m.p.h., with a maximum speed of 70 to 80 m.p.h., a ceiling of some 30,000 ft. can be obtained, and a maximum range of over 20,000 miles, or nearly once round the world. This colossal endurance and range of action can be achieved in large rigids because, contrary to H/A, the characteristics of L/A are governed by two factors:

1—The lift of a rigid is proportional to its cubic capacity (dimensions).

2—All fuel carried is used for forward propulsion and not, as in the case of H/A craft, chiefly for maintaining the structure in the air, the head resistance of the airship being small compared to that of an airplane of the same lift.

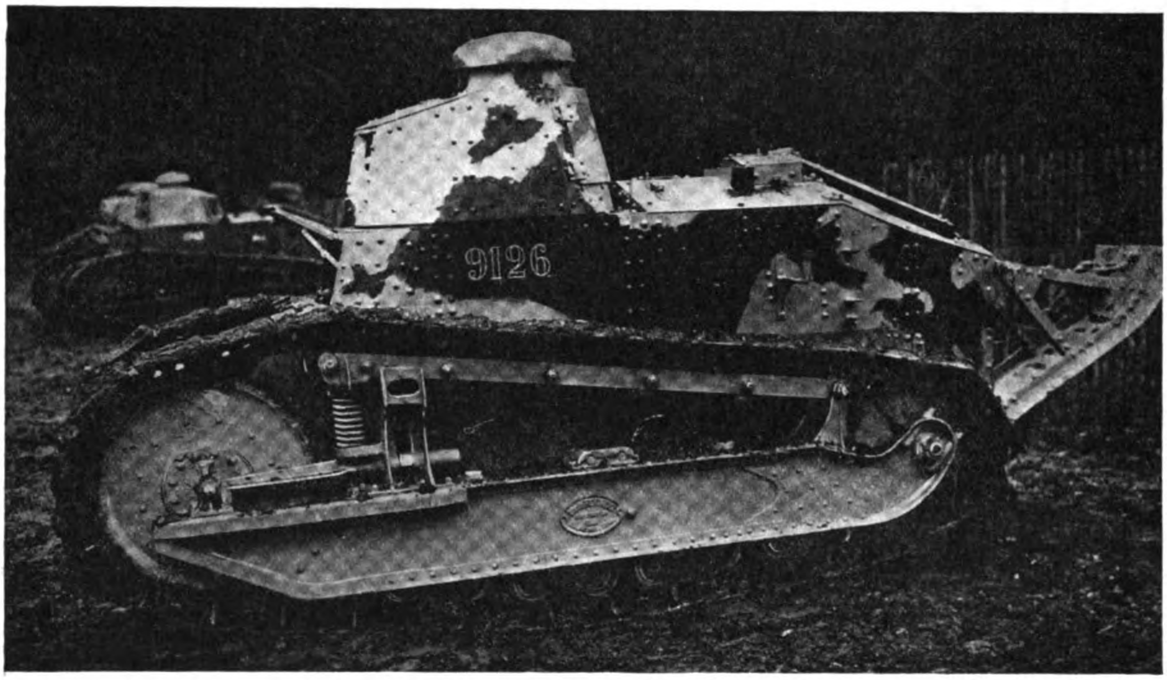
The French Baby Renault Tank

Weighs 6½ Tons Complete with Machine Gun—Has a Maximum Speed of 4.8 M.P.H.—Can Climb a Gradient of 119 Per Cent—Is Driven by a Small Four-Cylinder Engine and Can Be Handled Efficiently by Two Men

By W. F. Bradley
AUTOMOTIVE INDUSTRIES' *European Correspondent*



Showing the general construction of the Renault tank. The driving sprocket is at the rear, the endless band passes around a pulley at the front, and between these is a series of idlers and automatic tensioning apparatus

IN October, 1917, Louis Renault presented to the French War Department a new type of tank with the remark: "Try it out, and if it meets your requirements I can supply you thousands like it."

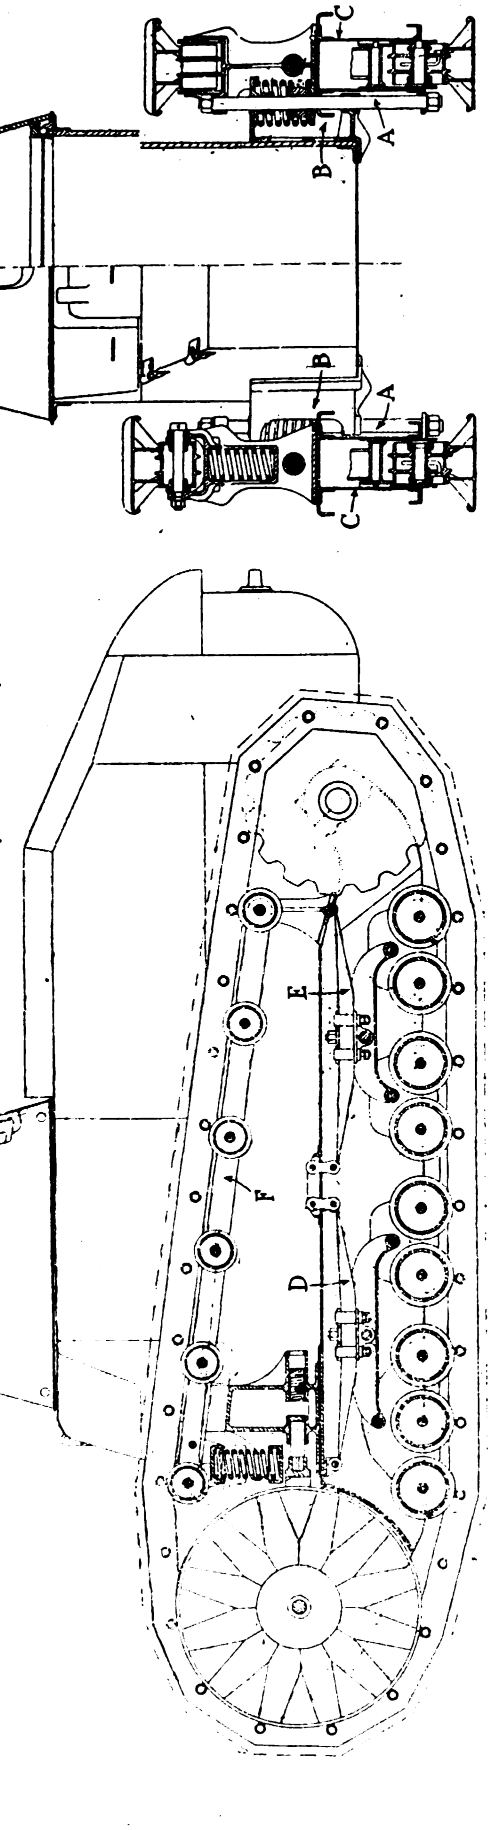
Up to this time France had followed in the wake of England so far as tank construction was concerned. The first British tanks, as is generally known, were huge structures of heavy weight and armament and of very slow speed. The French set to work on the same general lines, but were far from being as successful as their Allies. Not only were the first French tanks inferior in design and construction to the first produced in England, but they no longer possessed the factor of surprise for the enemy. Two or three types were made, both with mechanical and electrical transmission, but without in any case the results being satisfactory. Military men declare that the very best results were obtained when the big French tanks fell into the hands of the Germans, for our enemies immediately set to work to copy them, and in doing so accentuated all the worst defects. As a consequence, the German army has the worst tanks in Europe.

The big tank, weighing 30 tons and more, is slow, and difficult to maneuver. When under observation, its rate of travel being accurately known and its course being comparatively fixed, it becomes an easy target for artillery. Its rate of travel is about two miles an hour; experience has shown that this is too slow. Although popularly supposed to be able to travel anywhere, a big tank can get into positions from which it is impossible to extricate itself, and, the unit being big and important, the loss is considerable.

Acquainted with the general history of tank development, Louis Renault decided to strike out on different lines. He himself laid out the general plans, entrusted the details to his engineers, and had the first tank built entirely in his own automobile factory at Billancourt, near Paris.

Renault's tank weighs 6½ tons completely equipped with machine gun; it has a maximum speed of 4.8 miles an hour; it can climb a gradient of 119 per cent; its motor is a small four-cylinder of only 3.7 by 6.29 in. bore and stroke, and the machine can be handled with extreme ease by two men—one gunner and one driver. Owing to its small weight and area, the transportation of this tank aboard a truck is a very easy matter.

The first tests of this machine were so satisfactory that a big series was ordered at once. Work was carried out actively during the winter of 1917 and the spring of 1918, with the result that they were able to play a very important rôle in holding up the last German attacks in the early summer of 1918 and in carrying through to



Scale drawings showing the suspension of the Renault Baby Tank. The endless driving band is kept in tension by a lever F pivoted at the rear, furnished with a series of idler wheels and held up by a spring under the forward end of the lever

a successful issue the Allied attacks from July, 1918, to the signing of the armistice.

The general lines of these tanks are familiar by reason of the number of illustrations which have been published. The motor is at the rear; it drives through a four-speed and reverse gearset and a series of reduction gears to the large sprocket at the rear of the self-laying track. The driver is at the forward end. Behind him is the gunner, who operates either a machine gun or a cannon mounted in the revolving turret. This design divides the tank into two compartments: a rear one for the motor, transmission, radiator and gasoline tank, and a forward one for the driver and gunner. When in action the driver must remain seated; the gunner has standing room in his turret.

The Renault tank is divisbile into three components: the two side frame members with the main driving sprocket at the rear, the idler pulley at the opposite end, and the rollers and endless track between the two; the steel-plated body of the tank, containing the motor and reducing gears, attached to the side frame.

Details of Endless Tracks

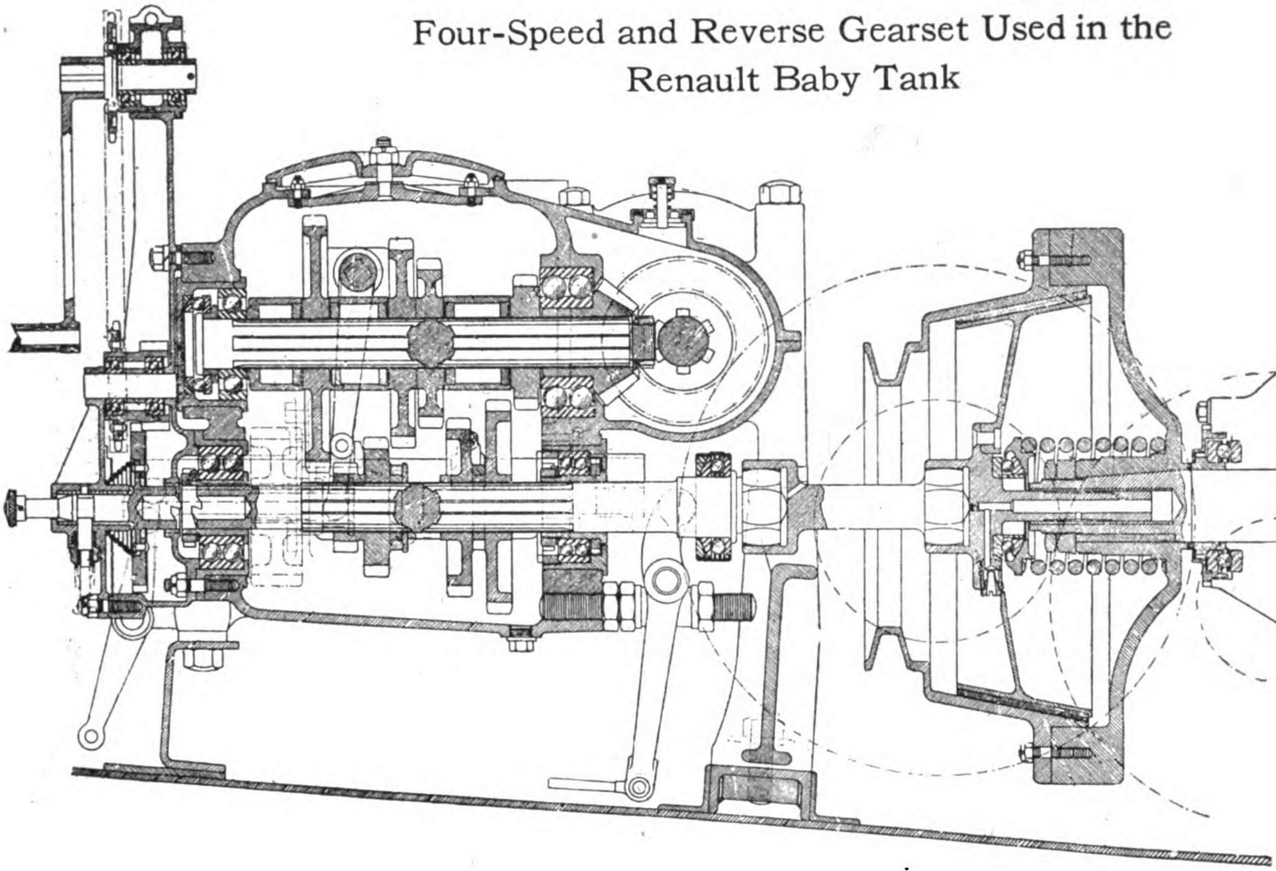
As Renault claims a patent for the construction of his endless tracks, they are worth describing in some detail. The frame members—by this term is understood the whole of the track-laying mechanism—are mobile in relation to the body of the tank, for they are pivoted around the rear axle, and at the forward end they are attached by means of two guiding bars, *A*, Fig. 1, secured to the body of the tank by means of the hangers *B*. Each of the main frame members *C* is carried by means of two laminated Springs *D* and *E* on two balance arms, on the extremities of which are four bogies. The wheels of these bogies run on the endless track.

The main driving sprocket is at the rear. At the opposite extremity is a larger diameter wooden pulley with a steel rim. This is shown in the drawing with spokes, but it is now disk construction. This forward pulley is carried in a fork, and has a lateral movement to allow of adjusting the endless band. In order to support the endless track between the driving sprocket and the jockey pulley there is a bar *F* pivoted at the rear, carried in guides at the front, and maintained in position by a coil spring under its forward end. This bar carries six rollers, and the arrangement gives a constant and automatic tension of the endless track, and at the same time supports it for a length of about 78 in. As the two tracks have a width of 13½ in. and a length of 110 in., the load per square inch is nearly 5 lb.

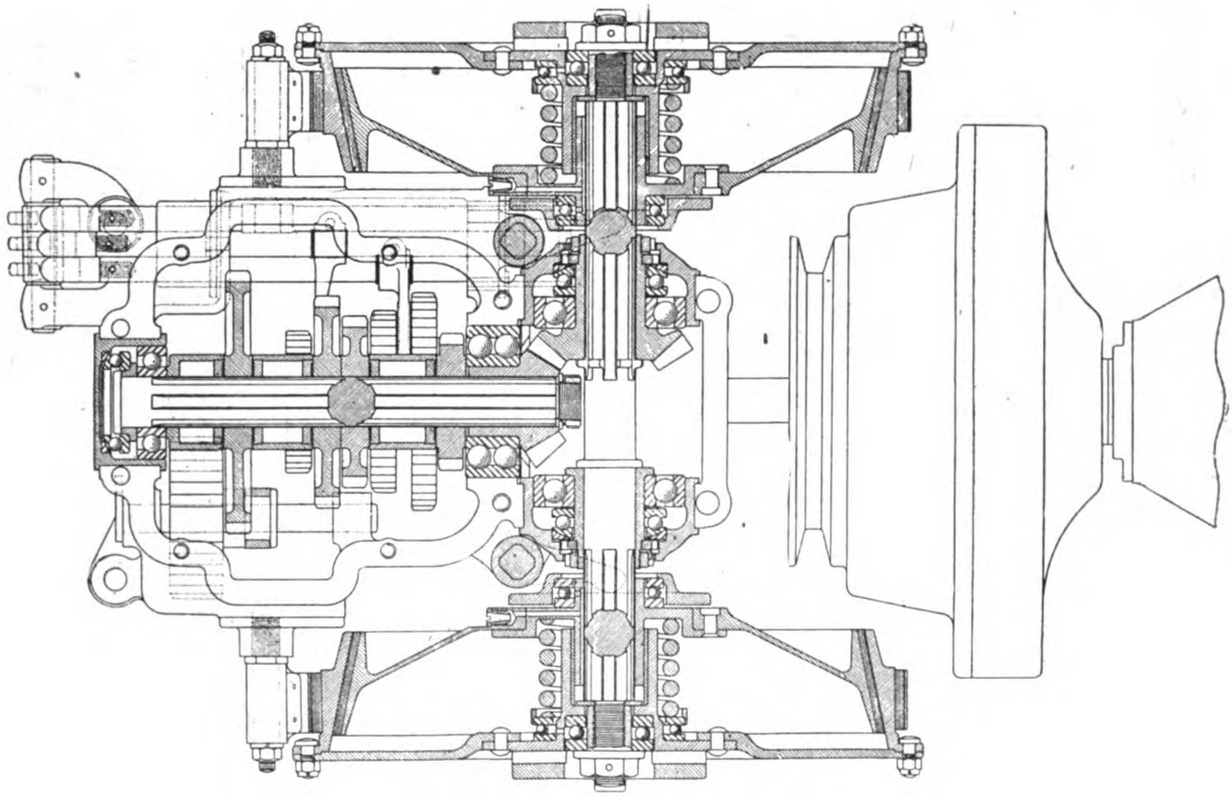
The individual links of the endless track are connected by means of case-hardened bolts having a diameter of 0.9 in. All the rollers have phosphor-bronze bushes. Trouble has been experienced in many makes of tanks with the breakage of the bolts connecting the links of the endless track. It is claimed that, providing the case-hardening is satisfactory, and the tracks are kept under correct tension, there is very little trouble with the Renault in this respect. The bushed rollers, too, have a comparatively long life. It is generally found that the track needs tensioning after 2 hours' hard running. After this it can be run 15 to 20 hours under severe conditions—in heavy mud and in water—before it needs further attention.

The body of the tank is an all-steel construction, varying in thickness from 0.6 to 0.3 in. The maximum thickness is found in the vertical sides; but most of the surface is either inclined or rounded, so that the tendency of a bullet or shell splinter would be to strike obliquely, and this allows thinner armoring to be made use of with security. The turret is mounted on ball bearings,

Four-Speed and Reverse Gearset Used in the Renault Baby Tank

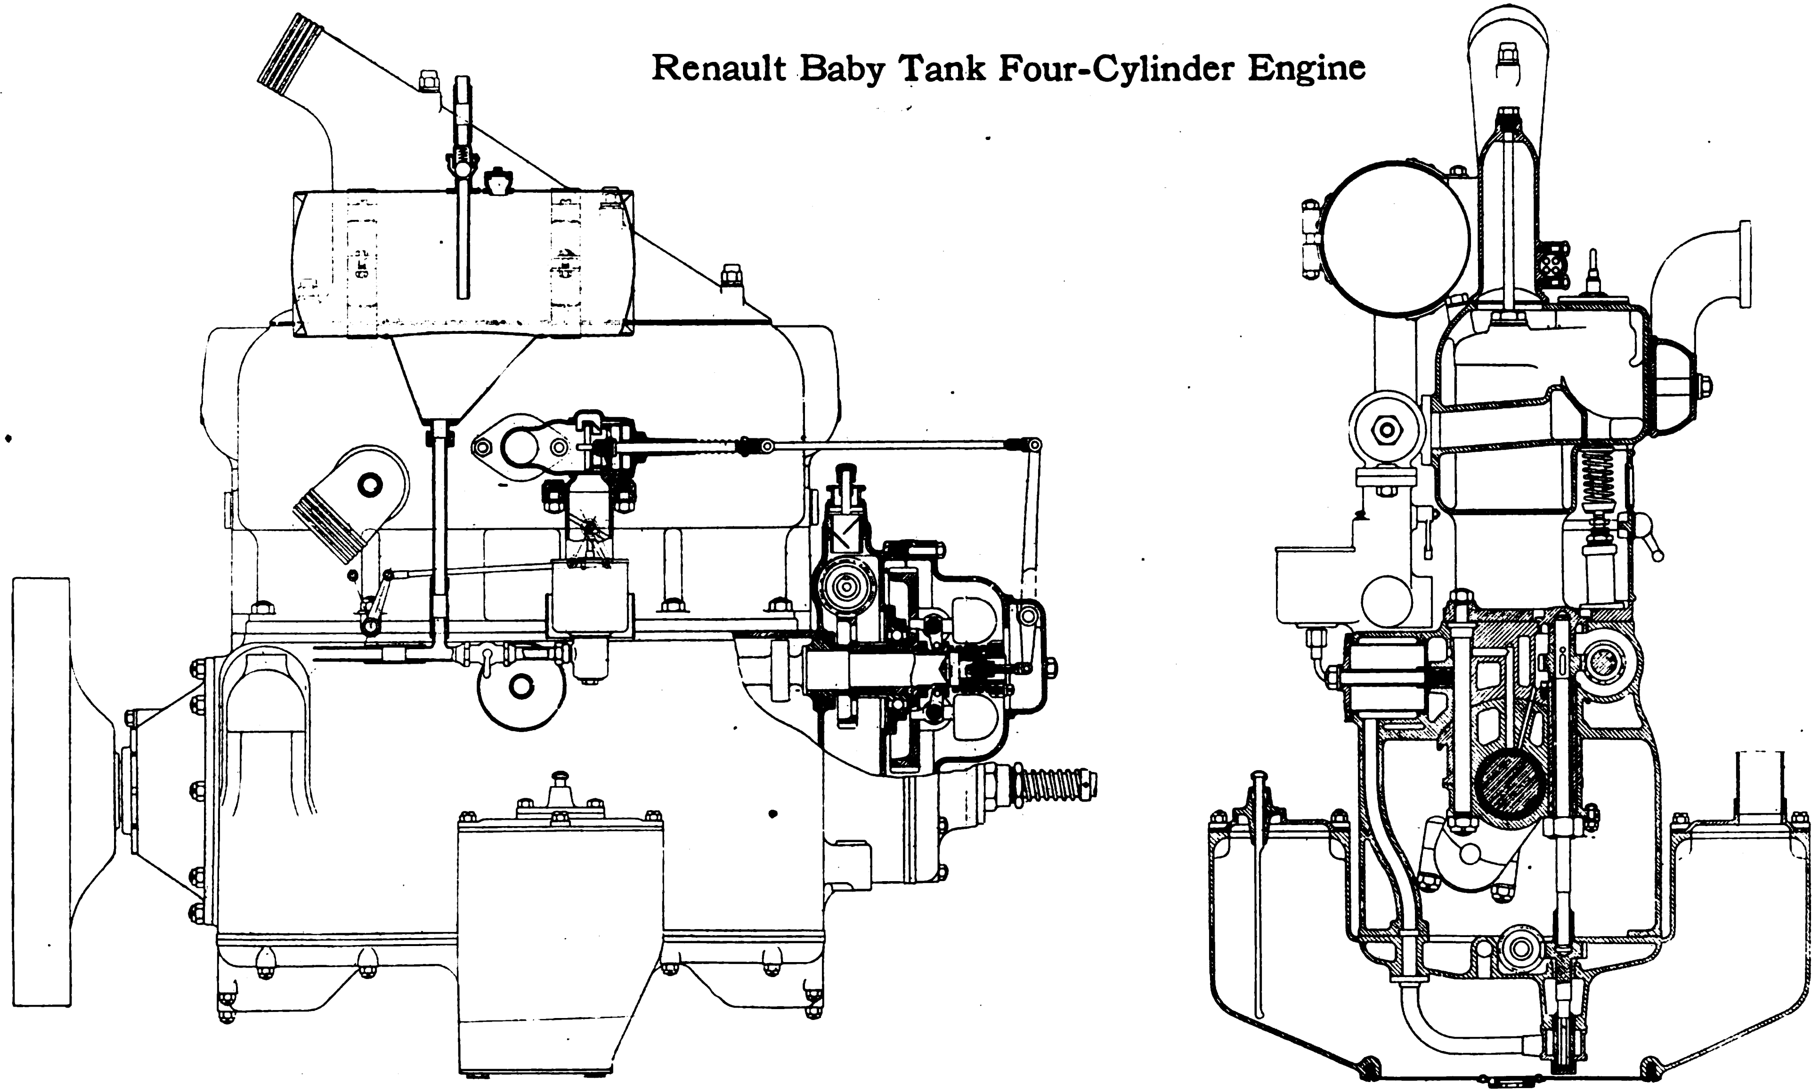


Power is transmitted to the endless driving bands of the tank through a cone clutch on the engine and four-speed gearset. Immediately behind the gearset is a transverse shaft which is driven by a bevel on the end of the intermediate shaft. Note the hand cranking device at the forward end



Horizontal section through the gearset, showing the two cone clutches, independently operated, which transmit the power to the endless driving band. Steering is accomplished by releasing one or other of these two clutches

Renault Baby Tank Four-Cylinder Engine



Part sectional views of the 3.7 in. by 6.9 in. four-cylinder engine used in the Renault two-man tank. The view at the left shows the governor-controlled Zenith carbureter which has an interesting method of feed. Gasoline is supplied under pressure from a main tank and any quantity above that taken by the engine is by-passed up to a reserve tank on the top of the engine, from which it overflows through a ball-check valve back to the main tank. The lubrication of the engine is of the dry sump type, oil being supplied to the bearings under pressure.

and carries in its interior either a machine gun or a cannon.

A four-cylinder engine of only 3.7 by 6.29 in. bore and stroke is much smaller than is popularly imagined to be necessary for a tank. It has been found, however, to be quite sufficient for the work. The actual horsepower developed is 30 at 1100 revolutions, 33 at 1200 revolutions, 35 at 1300 revolutions, and 39 at 1500 revolutions. The torque is 19.7 kilogram-meters at 1200 revolutions.

The lubrication and the gasoline feed systems are the most distinctive features about the motor. Its four cylinders are a block casting, the central bearing is of considerable length, and being a Renault construction the water circulation is by thermo-siphon. The radiator, a plain tubular type similar to those used on Renault trucks, is mounted transversely inside the tank body, ahead of the engine. A centrifugal fan, driven from the main shaft by a motorcycle type rubber belt, draws air in through all the openings in the body and expels it vertically. This not only cools the circulating water, but ventilates the entire tank. While it is admitted that the engine can be kept cooled without a water pump, this feature of the construction has been much criticised by the tank crews, who point out that they are at the mercy of a rubber belt. If this breaks in action the engine is almost certain to overheat and all ventilation is stopped.

Dry Sump Lubrication

Lubrication is of the dry sump type. There are two large capacity pumps, one at each end of the base chamber. These drive all the oil which drips from the bearings into the main oil reservoir, built under and to left and right of the central portion of the base chamber. A pump driven off the camshaft delivers the oil under pressure to the main bearings and to collector rings, which distribute it by centrifugal force to the connecting-rod bearings and to the wrist pins. With this dry sump and central oil reservoir the engine can operate at any inclination.

The motor has a governor operating on the throttle of a Zenith carbureter. The main gasoline supply is carried just ahead of the motor, the fuel being fed from this tank to the carbureter by means of an air pump driven off the camshaft. The excess gasoline not absorbed by the carbureter is carried up a vertical tube, Fig. 3, to a reserve tank immediately above the cylinders, and the overflow from this tank goes to the main tank by means

In this picture the tank is practically standing on its tail and consequently is being stabilized thereby

Showing the Renault tail, a feature which was added when its possibilities became apparent

of a standpipe. As the outlet of this pipe is provided with a ball check valve, the gasoline cannot return to the main tank unless a determined pressure has been reached in the reserve tank. This pressure is such that whatever the inclination of the vehicle, gasoline must be carried under pressure to the carbureter. As the reserve tank is airtight, the mass of air above the gasoline forms an elastic regulator of the gasoline pressure in the feed pipes. Also, if the pump ceases to work, the carbureter is fed from the gas carried in this reserve tank. As a precaution against pump failure there is a hand air pump by the side of the driver.

Steering Through Clutches

Power is transmitted from the motor through an inverted leather-faced cone clutch to a four-speed and reverse gearbox, Fig. 6. The intermediate shaft of this gearbox carries a bevel pinion at its rear end, engaging with a crown wheel on the transverse shaft. Fig. 7 shows how the power is transmitted from the gearset through two large diameter cone clutches lined with Ferodo to the reducing gear (not shown in this drawing). These lateral clutches can be operated independently, and by throwing out either one or the other both the reducing gear and the endless band on that side are stopped. Each set of reducing gears is contained in an aluminum housing mounted by the side of the motor, and consists of the first driven pinion, two intermediaries, and the final driven pinion carrying the endless band. Connection from the clutch shaft to the first pinion of the reduction gears is by means of an Oldham coupling, not shown in Fig. 7. The two sets of reduction gears are in dustproof and oil tight casings, and the whole construction is remarkably compact, the space occupied being very much less than the motor and gearset of a 3-ton truck.

The total gear ratios are 114.5 on first and reverse, 56.3 on second, 34.5 on third, and 22.3 on fourth gear. The reducing gears between the lateral clutches and the main driving pinion carrying the endless band have the following ratios: 58:12, 30:16 and 38:13. The drawbar pull is 11.090 lb. on first and reverse and 992 lb. on fourth speed.

The total length of the Renault tank, without tail, is 161 in.; total width is 66 in.; track, measuring from center to center of the bands, is 55 in.; distance between the two main wheel centers (main driving pinion and main pulley) is 110 in.; the width of the endless bands is 13½ in., and the total height of the machine is 84 in. The weight is 6½ tons with machine gun.

Front view of the tank with all doors open. The driver is grasping the right-hand clutch lever

The driving of these tanks is a remarkably simple operation. The driver sits on a cushion on the floor, with his back supported by a transverse girth. He has the same pedal controls as on a standard automobile: clutch, brake and accelerator. To his right is a selective change-speed lever, giving four combinations ahead and one reverse. There is no steering wheel. In its place are left and right-hand levers. By pulling out the left-hand lever the left-hand lateral clutch is withdrawn and the left-hand track is stopped. To make a quick turn the left-hand clutch lever is pulled further to the rear, when it applies a band brake on the left-hand clutch drum, thus locking the left-hand track and causing the whole machine to pivot around. To turn to the right the same movements are made with the right-hand lever.

A mobile tail is bolted to the rear of the tank. The object of this is to facilitate the passage through holes and trenches. When a tank is obliged to crawl down into a trench the tail finds a support against the bank, thus decreasing the inclination of the machine and giving a support for climbing up the opposite bank. Briefly, it has the same functions as the crocodile's tail.

The military organization of the tanks is in companies of twenty, one of which is the commanding officer's tank, provided with wireless, and in consequence not carrying cannon or machine gun. When going into action the commanding officer keeps in communication with headquarters by means of his wireless and communicates orders to the men of his company by means of signals. As the chief work of the tanks is to destroy machine-gun nests, about half the machines in each company are fitted with a machine gun and half with a cannon. Each company has attached to it a mechanical staff of one non-commissioned officer and half a dozen mechanics, who are provided with a truck and hand tools, and are capable of carrying out all slight repairs.

The moderate weight of these tanks and their comparatively small dimensions make their rapid transportation to different portions of the battle front a very easy matter. A loading platform can be built by a gang of men in two or three hours. Gasoline or steam trucks with flat bodies can be backed up to this platform, and the tanks run aboard under their own power. With a single platform a company of twenty tanks can be loaded in an hour, and when loaded can be moved away at an average speed of 10 miles an hour. Thus, between sunset and sunrise a fleet of Renault tanks can be moved a distance of about 80 miles, and immediately on being unloaded they are ready to proceed to the fighting line and go into action. Or the tanks can be grouped 60 miles in the rear of the battle line, where they are completely hidden from enemy observation, and the following morning they can get into action to the complete surprise of the enemy. This extreme mobility is one of the most valuable features of the Renault type tank compared with the big machines, which must necessarily, on account of their weight, always proceed under their own power, at a road speed of only 2 or 3 miles an hour.

Driving Is Simple

There has never been any difficulty in training all the men that were required for handling the Renault tanks. Recruits are asked for, and usually young men are selected, but it is not considered necessary that they shall have had previous automobile experience. They are first of all taught to drive a touring car, then are given some practical instruction in general motor mechanics. After this they go right into the tank school. The control of the Renault tank is so simple that any person who can drive an automobile is capable of taking one across country after a few minutes preliminary instruction. Skill and judgment have to be acquired in the manner of tackling different kinds of trenches and shell holes, but this is not a long process.

There is no doubt that Louis Renault was on the right line of thought when he decided on the reduction in size and weight of tanks and the limiting of the crew to two

(Continued on page 506)

Small Inlet Valves Satisfactory in Overhead Valve Design

Improvement in Fuel Consumption with Increase of Speed Is Clear and Unmistakable—Thermal Efficiency Independent of Load and R.P.M.

PART II

THE advantage of 16 per cent higher brake mean effective pressure in the valve-in-head design than in the L-head design is due to the shape of the combustion chamber.

Mr. Pomeroy said: Fig. 7 is a diagram showing the following relationships:

1. The average brake mean effective pressure at various revolution speeds for the tests in which the inlet gas velocity was under 300 feet per second.
2. The compression pressures (gage) corresponding to the above. Table VI. shows the tabular values corresponding to Fig. 7.

TABLE VI.

Revs. per minute	A: "p, lb. per sq. in.	A: Compression pressure, lb. per sq. in.	B: "p, lb. per sq. in.	B: Compression pressure, lb. per sq. in.
800	80	91	83	94
1,200	83	94	94	101
1,600	83	99	96	104
2,000	81	101	94	103
2,400	78	98	91	99

The general characteristics of the curves are:

1. A rapid rise up to speeds of 1,000 to 1,200 revs. per minute.
2. A slow rise to a maximum of about 1,600 revs. per minute.
3. A gradual fall as the speeds increased to 2,400 revs. per minute.

The rapid rise in brake mean effective pressure in engine B is probably due to the fact that the engine is fitted with a light flywheel and presents greater difficulties in taking slow speed tests. In both engines it was very difficult to get accurate readings at speeds of 800 revs. per minute or under.

It will be seen that the compression curve of engine A rises more rapidly than that of engine B, and approximates to the latter at speeds over 1,800 revs. per minute.

Further, the brake mean effective pressure in engine A is appreciably more independent of the compression pressure at the various engine speeds than in engine B.

The most significant point, however, is the very distinct difference between the average brake mean effective pressures obtained in the two engines, approximately 13 lb. per sq. in.

The author is somewhat at a loss to account for this in view of the almost identical construction of the engines. The detailed figures which have been given in Tables I and II seem to exclude any simple explanation which might be suggested on the grounds of varying compression pressure, carburetion, etc.

Many subsidiary tests were made to throw some light on this question, among them the fitting of light aluminum pistons to engine A, the fitting of different carbureters, alterations of valve settings, in fact, the whole resources of the tuner-up were invoked with no result; engine A seemed completely indifferent to all such treatment.

From these experiments the author considers that the cause of the difference in brake mean effective pressure, which gives engine B an advantage of some 16 per cent over engine A, can only be sought in the feature in which the engines differ most, *i. e.*, the combustion chamber.

The combustion chamber of engine A was of the orthodox side-by-side valve design, the two valves being in a pocket projecting laterally from the cylinder barrel and being formed in part by the valve caps screwed in from the top of the cylinder. In the case of engine B the combustion chamber was also pocketed laterally, the two exhaust valves being in one pocket and the inlet partly in another, partly

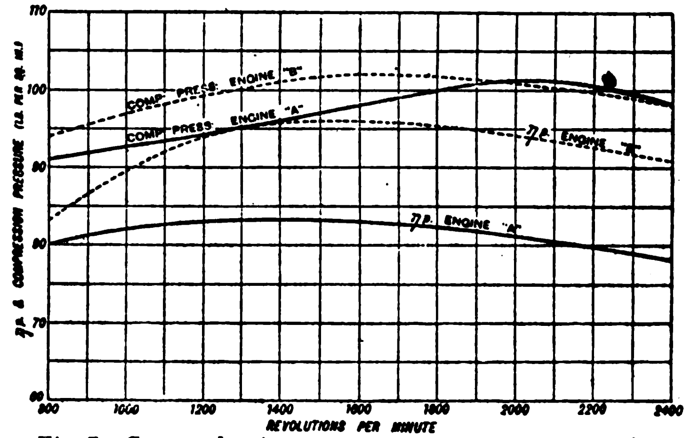

Fig. 7—Curves showing compression pressures in relation to r.p.m.

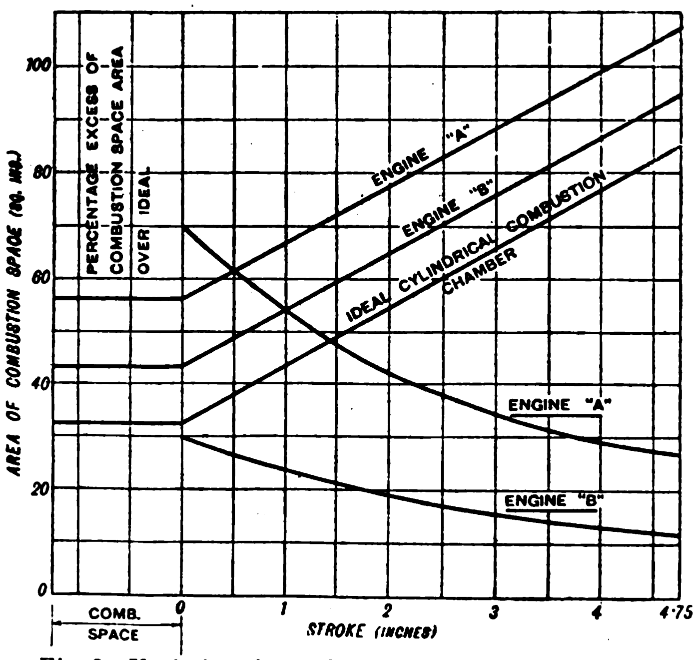

Fig. 8—Variations in combustion area from the ideal in engines A and B, expressed as percentages

discharging direct into the cylinder barrel. The valves were inserted from inside the cylinder.

The ratio of surface of combustion chamber to volume is as follows:

Engine A	4.66:1
Engine B	3.6:1
Ideal cylindrical type	2.75:1

The proportions of water jacketed to unjacketed surface in each case are approximately as follows:

	Water jacketed	Unjacketed
Engine A	30.4 sq. in.	25.6 sq. in.
Engine B	24.8 sq. in.	18.2 sq. in.
Ideal cylindrical type ...	18.3 sq. in.	14.7 sq. in.

Fig. 8 is a diagram showing the area exposed to cooling at each point of the stroke. From this it will be seen that the area of the combustion chamber in engine B is about midway between that of engine A and that of the quasi-ideal cylindrical type. Expressed as percentages, the excess of the surface over the ideal in engines A and B is given in the curves in Fig. 8. At the top dead center the excess of combustion chamber area over that of the ideal cylindrical type is 70 per cent in the case of engine A and 30 per cent in the case of engine B. At the bottom dead center the figures are 27 per cent and 12 per cent respectively. These figures are striking and suggest that in the ratio of surface to volume of the combustion chamber may lie the reason for the increased brake mean effective pressure found in engine B.

If such is the case it is of interest to compare the performance of engines A and B with that of an "ideal" engine of the same proportions.

Following Mr. Ricardo's analysis of the various factors concerning engine performance given in Mr. Berriman's paper before the Institution last month, it will be found that for a compression ratio of 4.8:1 the ideal indicated mean effective pressure is 134 lb. per sq. in.

In these engines, however, the inlet valve does not close till a crank angle 45 per cent past the bottom center, corresponding to an upward piston movement of 0.4 in. This is equivalent to shortening the compression stroke and alters the compression ratio accordingly, which now becomes

$$\frac{4.8 \times 4.35}{4.75} = 4.4:1.$$

Checking this against the actual compression pressure, say 100 lb. per sq. in., and assuming that the pressure in the cylinder at the moment of closing the inlet valve is 14.7 lb. per sq. in.:

$$P_1V_1^n = P.V.^n$$

$$\frac{114.7}{14.7} = 4.4^n$$

$$7.8 = 4.4^n$$

or $n = 1.37$, a value for n which is not unreasonable.

The indicated mean effective pressure corresponding to this corrected compression ratio is 128 lb. per sq. in.

Fig. 9 and Table VII show the following:

Curve 1. Revolution speed and brake mean effective pressure engine A.
Curve 2. Revolution speed and brake mean effective pressure engine B.
Curve 3. Revolution speed and brake mean effective pressure ideal engine (calculated).
Curve 4. Revolution speed and calculated indicated mean effective pressure engine A.
Curve 5. Revolution speed and calculated indicated mean effective pressure engine B.
Curve 6. Revolution speed and calculated indicated mean effective pressure ideal engine.

The calculated figures in the above are obtained by taking the figures given above, and adding to these a mean pressure for the suction exhaust loop of the diagram of 2 lb. per sq. in. at 800 revs. per minute, and 5 lb. per sq. in. at 2,400 revs. per minute.

The indicated mean effective pressures are seen to be remarkably constant with respect to revolution speed, but the

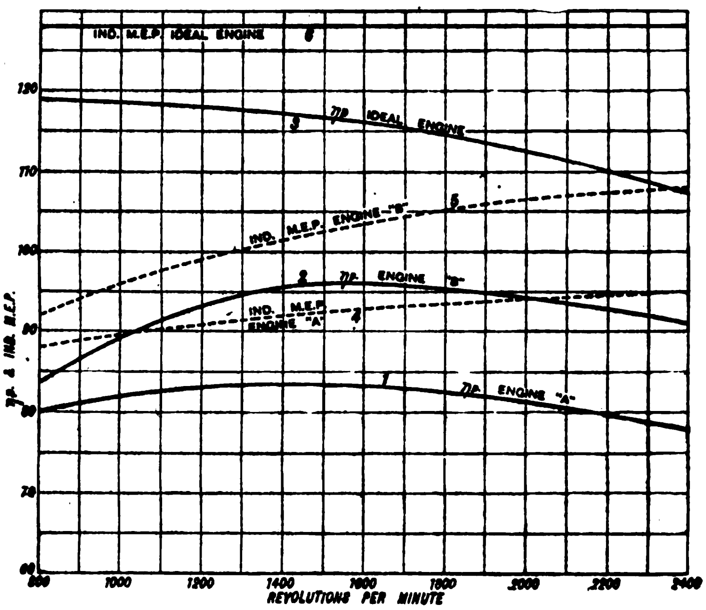

Fig. 9—Mean effective pressure of the engines under test at various speeds

difference between engines A and B, of course, remains. Comparing the average mean effective pressures in Table VII, the ideal engine gives 128 lb. per sq. in., engine A 93 lb. per sq. in., engine B 104 lb. per sq. in.

The chief advantage which might be expected in respect of the more compact combustion chamber in engine B is that the jacket loss during explosion and expansion would be less, and that part of this gain would be reflected in an increased mean effective pressure. The fuel consumption results, however, do not support this view. Table VIII gives the calculated indicated fuel consumptions, and shows that although the thermal efficiency increases with the speed, the actual consumptions are substantially the same in each engine at any given speed.

The greater mean effective pressure in engine B compared to engine A is not therefore susceptible of explanation on the grounds of greater thermal efficiency. It is of interest, however, to consider briefly the relationship between jacket loss and thermal efficiency.

The fuel supplied to an internal combustion engine can be accounted for mainly under the following heads:

1. Indicated work.
2. Heat lost to jacket.
3. Heat lost to exhaust.
4. Heat lost due to imperfect combustion.

No measurements of items 2 and 3 separately have, to the author's knowledge, been made on small gasoline engines, the usual measurements in engine tests being that of heat rejected to cooling water, which includes a large part of that which should properly be credited to the exhaust.

TABLE VII.

Lb. Per Sq. In.

Revs. per minute	Ideal Engine Ind. M.E.P.	Ideal Engine np	Engine A Ind. M.E.P.	Engine A np	Engine B Ind. M.E.P.	Engine B np
1,200	128	118	91	83	101	95
1,600	128	116	93	83	105	96
2,000	128	113	94	81	106	96
2,400	128	109	93	78	104	91

TABLE VIII.

Calculated indicated consumption. Pts. per B.H.P. per hour.

Revs. per minute	Ideal Engine	Engine A	Engine B
1,200	0.49	0.81	0.81
1,600	0.49	0.72	0.69
2,000	0.49	0.62	0.62
2,400	0.49	0.62	0.63

The subject of the proper division of the various losses has, however, been investigated in connection with slow speed gas engines by Clerk and Gibson and Walker experimentally, and by Lanchester before this Institution.

In the latter paper Lanchester shows that the heat lost to the jacket can be approximately expressed as being in part a constant loss fixed by the size of the engine, and the remainder as a constant percentage of the total fuel heat, due mainly to internal radiation, which can be expressed as a percentage of the horsepower.

Both experiment and calculation show that for an engine with an ideal cylindrical combustion chamber the jacket loss is a smaller proportion of the total heat supplied at high speeds than at low speeds. The difference, however, at full load is not great. For speeds of 100 revs. per minute to 250 revs. per minute Messrs. Gibson and Walker found the jacket loss varied from 20 per cent to 16 per cent of the total heat.

The effect of this reduction of jacket loss upon thermal efficiency is very small. In Messrs. Gibson and Walker's experiments the increase in indicated thermal efficiency for an increase in speed at full load from 100 revs. per minute to 250 revs. per minute was about 1 per cent. The reduced jacket loss was accompanied by an increased loss to exhaust of almost the same amount.

The reason for this is that a large part of the jacket loss occurs after expansion, and obviously cannot affect thermal efficiency.

Messrs. Gibson and Walker's experiments were carried out upon a gas engine, and it is known that combustion was practically complete.

In the engines under discussion there is reason to doubt if combustion is complete, owing to the extended nature of the combustion chambers and the fact that a considerable fraction of the charge may have been rendered non-effective due to being in contact with a comparatively cold surface.

Deficiency from the Ideal

The surface of the combustion chamber in engine A is, as has been said, 56 sq. in.; that in engine B 43 sq. in. The compression volume is 12 cu. in. A non-effective layer of gas 1/16 in. thick in each combustion chamber would entail a loss of 29 per cent of the fuel supplied to engine A, and 23 per cent in the case of engine B, with corresponding reduction in the mean effective pressure compared to the ideal. The actual deficiency compared to the ideal is 27 per cent in engine A, and 18 per cent for engine B.

The high fuel consumption in both engines on full load at low speeds also suggests incomplete combustion. The mixture supplied was of such richness as to be scarcely combustible if homogeneous, yet no extra air could be supplied to the engines in the low speed tests. With increase of speed combustion apparently becomes more complete with consequent reduction of the fuel wasted per stroke.

Another characteristic of an extended combustion chamber is that of the relatively sluggish ignition which takes place therein. In the tests under discussion engine B was more sensitive to the position of the spark than engine A.

The author is conscious of the vagueness of this attempt to explain the difference in the mean effective pressures of engines A and B as compared with each other and also in terms of increase of engine speed. The phenomenon of combustion in such small combustion chambers is undoubtedly very complex, and there is ample scope for experiment to determine the extent to which heat loss and mean effective pressure are affected by combustion chamber shape and revolution speed, and the true explanation thereof. The general conclusion in respect of the influence of revolution speed upon brake mean effective pressure is that the rise in brake mean effective pressures at the lower speeds is due to the diminishing effects of incomplete combustion, while at the higher speeds these influences are more than negatived by the decrease in mechanical efficiency, thus causing the characteristic slow fall in the brake mean effective pressure—revolution per minute curve.

A—Full Load

Deduction.—Whatever the cause, the evidence as to improvement in fuel consumption with increase of speed is clear and unmistakable.

Mr. Pomeroy analyzed the performances as follows:

In both engines A and B the fuel consumption at 800 revs. per minute is about one pint per brake horsepower per hour, and falls to about 0.72 pints per brake horsepower per hour at 2400 revs. per minute. As mentioned in the previous section, no great improvement would be expected due to reduction in jacket loss with an engine in which the combustion chamber was of compact form. On the other hand, there is ample evidence that combustion is more complete with increase of engine speed. The fact that the fuel consumptions in the two engines are so nearly the same, while the combustion chamber proportions are so different, calls for some explanation. The author suggests that this is due to delayed combustion of what may be called the surplus fuel supplied. If this is being burnt more or less non-effectively during the latter part of the expansion stroke, and quite non-effectively during the exhaust stroke, the *excess* of combustion chamber surface in engine A over that of engine B must be considered as a fraction of the total surface exposed during the process of delayed combustion, in which case it becomes so small as to be negligible. Whatever the cause the evidence as to improvement in fuel consumption with increase of speed is clear and unmistakable.

B—Varying Loads

The average consumptions of engines A and B at varying loads are given in Table IX:

Engine A Revs. per Minute	Engine A Pts. per B.H.P. per Hour Consumption	Engine A Load	Engine B Revs. per Minute	Engine B Pts. per B.H.P. per Hour Consumption	Engine B Load
2,400	0.73	Full	2,400	0.72	Full
2,000	0.74		2,000	0.71	
1,600	0.79		1,600	0.76	
1,200	0.87		1,200	0.88	
800	0.99		800	1.12	
2,400	0.71	0.8 full load	2,400	0.74	0.8 full load
2,000	0.73		2,000	0.71	
1,600	0.77		1,600	0.73	
1,200	0.84		1,200	0.78	
800	0.98		800	0.86	
2,400	0.82	0.6 full load	2,400	0.81	0.6 full load
2,000	0.84		2,000	0.77	
1,600	0.88		1,600	0.81	
1,200	0.97		1,200	0.87	
800	1.15		800	0.97	
2,400	0.98	0.4 full load	2,400	1.0	0.4 full load
2,000	1.05		2,000	1.0	
1,600	1.12		1,600	1.04	
1,200	1.24		1,200	1.06	
800	1.38		800	1.19	

An inspection of this table reveals the fact that on the whole in both engines the best fuel consumptions occur at 0.8 full load.

The effect of increased speed from 800 revs. per minute to 2400 revs. per minute may be expressed as follows:

Improvement in Consumption with Increase of Speed from 800 revs. per minute to 2400 revs. per minute

	Engine A	Engine B
Full load	26 per cent	35 per cent
0.8 Full load	27 per cent	11 per cent
0.6 Full load	28 per cent	16 per cent
0.4 Full load	29 per cent	16 per cent

The figures are not conclusive, but they indicate that broadly the improvement in consumption with increase of speed is of the same order at part load as at full load.

The average consumption throughout the speed range of 800 revs. per minute to 2400 revs. per minute is given in Table X for the various fractions of full load.

TABLE X

Average Consumption

Pints per Brake Horsepower per Hour

800 *revs. per minute to* 2400 *revs. per minute*

	Engine A	Engine B
Full load	0.83	0.71
0.8 Full load	0.83	0.78
0.6 Full load	0.95	0.86
0.4 Full load	1.18	1.05

From this it is seen that the effect of increasing the load from 0.4 to full load, *i. e.*, 150 per cent, is to cause an improvement in consumption of 29.6 per cent in engine A, and of 32 per cent in engine B.

The conclusion from the above is that on the one hand an increase of speed of 100 per cent improves consumption in the order of 25 per cent irrespective of load, and on the other that an increase of load of 150 per cent irrespective of speed causes an improvement in consumption in one engine of 29.6 per cent, and in the other of 32 per cent.

Fuel Consumption Per Hour for Any Given Horsepower

Deduction.—For small gasoline engines working between 25 and 50 per cent of their maximum brake horsepower, the brake thermal efficiency for any given horsepower is independent of the load and revolutions per minute of engine.

Mr. Pomeroy completed his analysis as follows:

The conclusion of the last section leads directly to the main point of practical interest in the paper: In automobile design, the conflicting interests of fuel consumption and engine speed which are usually supposed to lead in general to the use of the highest top speed gear ratio consistent with preserving enough excess torque to enable the vehicle to climb hills without gear change to an extent sufficient to placate the user.

The use of a low top speed gear ratio is commonly understood to carry with it the penalty of excessive consumption.

In the last section it has been shown that both increase of load and increase of speed carry with them reduction of consumption to somewhat the same extent, *i. e.*, 100 per cent increase of load reduces consumption in the same order as 100 per cent increase of speed.

The chief function of an automobile engine is the performance of a given task. In order to propel it at, say, thirty miles per hour on the level a given horsepower is required. Further, this horsepower is only a small fraction of that capable of being developed. In the case of a medium-sized touring car the horsepower exerted at thirty miles per hour is only about 25 per cent to 40 per cent of the maximum it is capable of developing according to the size of the engine and the top speed gear ratio or engine speed.

Selection of Gear Ratio

In selecting the gear ratio for a given engine the designer has obviously a wide range of choice for the development of such a small fraction of the total power available. He can, for example, with an engine such as those under discussion obtain the requisite horsepower at, say, 500 to 600 revs. per minute at full load, or at 2000 revs. per minute at, say, quarter load. In the first case there is no reserve for hill climbing; in the second, the engine revolutions would be a very long way above those appropriate to maximum horsepower before the car was traveling at the speed of which it would otherwise be capable. It is obvious that between these extremes lies the most suitable gear ratio.

If fuel consumption is regarded as being to any extent inversely proportional to engine speed it is necessary to keep the gear ratio as high as possible. On the other hand, if this consideration can be neglected the gear ratio can be chosen so that the engine speed at the maximum car speed on the level corresponds to that of maximum brake horsepower. It can, in fact, go well over this owing to the usual flat top of the curve relating brake horsepower and engine speed.

Consideration of Fuel Consumption

The question is, can considerations of fuel consumption be neglected? The author considers that this can be answered in the affirmative over a large range of engine speed and load.

Horsepower depends upon the product of torque and speed. If consumption varies inversely to the same extent for the same percentage variation of torque and speed, it is obviously a matter of indifference whether a high or low gear ratio is used so far as consumption is concerned.

In the last section some figures relating to the change in consumption with load and speed were given which support this view. Figs. 10 and 11 show the fuel consumption per hour, brake horsepower, and revolutions per minute plotted on three planes of projection for each engine.

Taking the consumption per hour for 10 hp. between speeds of 1200 revs. per minute and 1800 revs. per minute, the increase in consumption is from 11.5 to 12 pints per hour. It follows, therefore, that for an additional consumption of one pint per hour the designer can produce a car with a reserve torque capacity greatly in excess of that usually given.

To confirm the above the author has carried out road tests on his own car fitted with engine A, the car being driven as nearly as possible at a constant speed of 20 miles per hour and 30 miles per hour on top and third speeds respectively.

The results are as follows:

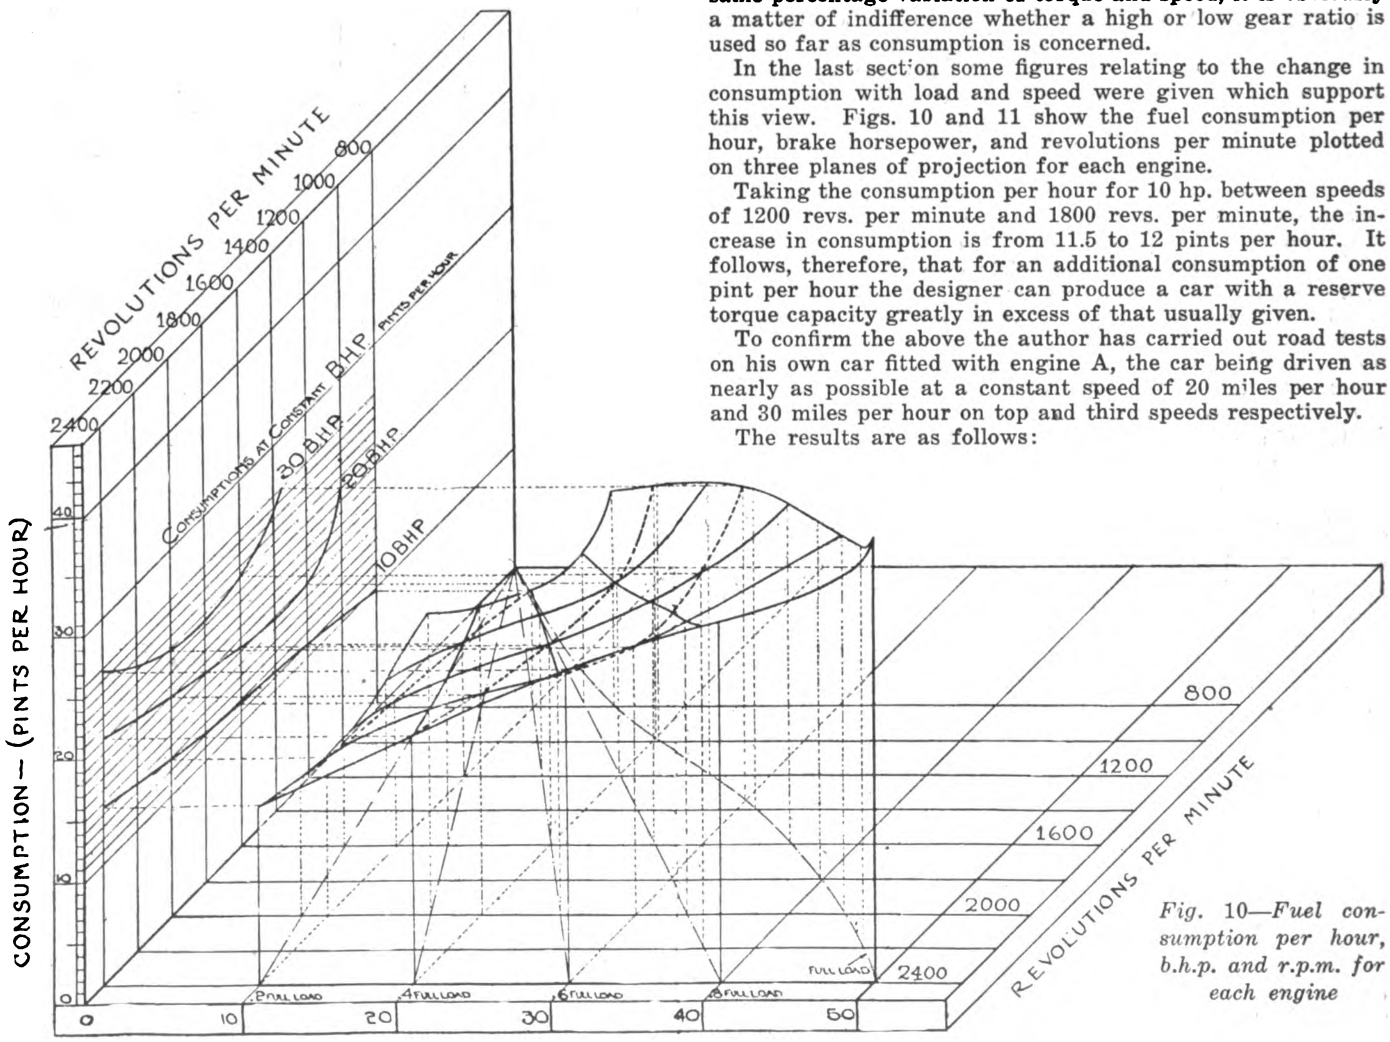

Fig. 10—Fuel consumption per hour, b.h.p. and r.p.m. for each engine

Top speed	Engine revs. per minute	Miles per gallon	
20 m.p.h.	860	24.7	
30 m.p.h.	1,290	23.0	
Third speed			
20 m.p.h.	1,320	21.8	(24)
30 m.p.h.	1,970	19	(21)

In parentheses alongside the actual road consumption is given the consumption allowing for a loss of 10 per cent due to oil churning, gear friction, etc., when running on third speed.

The horsepower necessary to overcome the tractive resistance at 20 miles per hour is about seven, and at 30 miles per hour about twelve. The maximum brake horsepower developed at corresponding engine speeds is about 16 and 25 respectively on top speed. The maximum brake horsepower developed at the same road speeds but at engine speeds corresponding to third speed gear is about 27 and 39 respectively. The power exerted by the engine in these tests therefore varies from about 25 per cent to 50 per cent of full load.

In short, for small gasoline engines working between 25 per cent and 50 per cent of their maximum brake horsepower, the brake thermal efficiency for any given horsepower is independent of the load and revolution speed.

Deductions and Lessons

In conclusion, the author is aware that a series of tests extending over many months such as those described are susceptible of criticism on the grounds of doubt as to their strictly scientific accuracy in view of the infinite number of varying conditions entailed. In spite of this the author feels that the experimental data are substantially accurate. Constant experience with one or two engines produces a very accurate sense of any departure from the normal, and causes the repetition of any tests which seem to be unreasonable.

The principal lessons from the work done are in the opinion of the author the evidence of the high charging capacity of a small overhead inlet valve and the comparative independence of consumption in respect of engine speed and torque for horsepowers up to 50 or 60 per cent of the maximum.

There are many designers now engaged upon the design of overhead valve engines for touring cars inspired by either aero engine practice or the fashion in America, as the case may be. The author would remark that the development of overhead valve engines is being caused not so much on technical or scientific grounds as by the fact that with the ordinary type of engine the fitting of a dynamo and self-starter both carried on the engine is well-nigh impossible.

Utility of Industrial Laboratories

AMONG the reasons for the success of German industries in the period preceding the war must be reckoned the recognition of the importance of the union of science and practical work, demonstrated by the value ascribed in Germany to industrial laboratories, says a writer in *Le Genie Civil* for Oct. 18. The results, however, obtained up to the present in France have been disappointing when viewed from the financial standpoint, and the author fears that laboratories founded for the purposes of the war will be abandoned as soon as peace is declared.

After laying stress upon the distinction between a laboratory for merely testing the qualities of the product of a given factory and a laboratory for research work proper, he remarks that the manufacturer will rarely hesitate about a reasonable expenditure on the former, but is difficult to convince about the value of the latter. He considers that there is too much individualism among French manufacturers and too little recognition of the work of their subordinates, and he pleads finally for a wider extension of the research laboratory.

British Want Ministry of Ways and Communications

IN England there is a movement on foot at the present time looking toward the establishment of a separate Ministry of Ways and Communications. The Commercial Motor Users' Association, which corresponds to our Motor Truck Club, has placed itself on record as favoring the proposition by adopting the following resolution:

"The National Council of the Commercial Motor Users' Association (Incorporated), having considered the proposal to place the control of (a) roads and road transport, and (b) railways under the same ministry, is of opinion, the interests concerned being seldom identical and sometimes conflicting, that housing and other national reconstruction programs, and development of industrial and agricultural road transportation, are likely to be retarded unless such control be entrusted to distinct and separate ministries, or guarantees of like effectiveness be provided by the government in any new departmental organization."

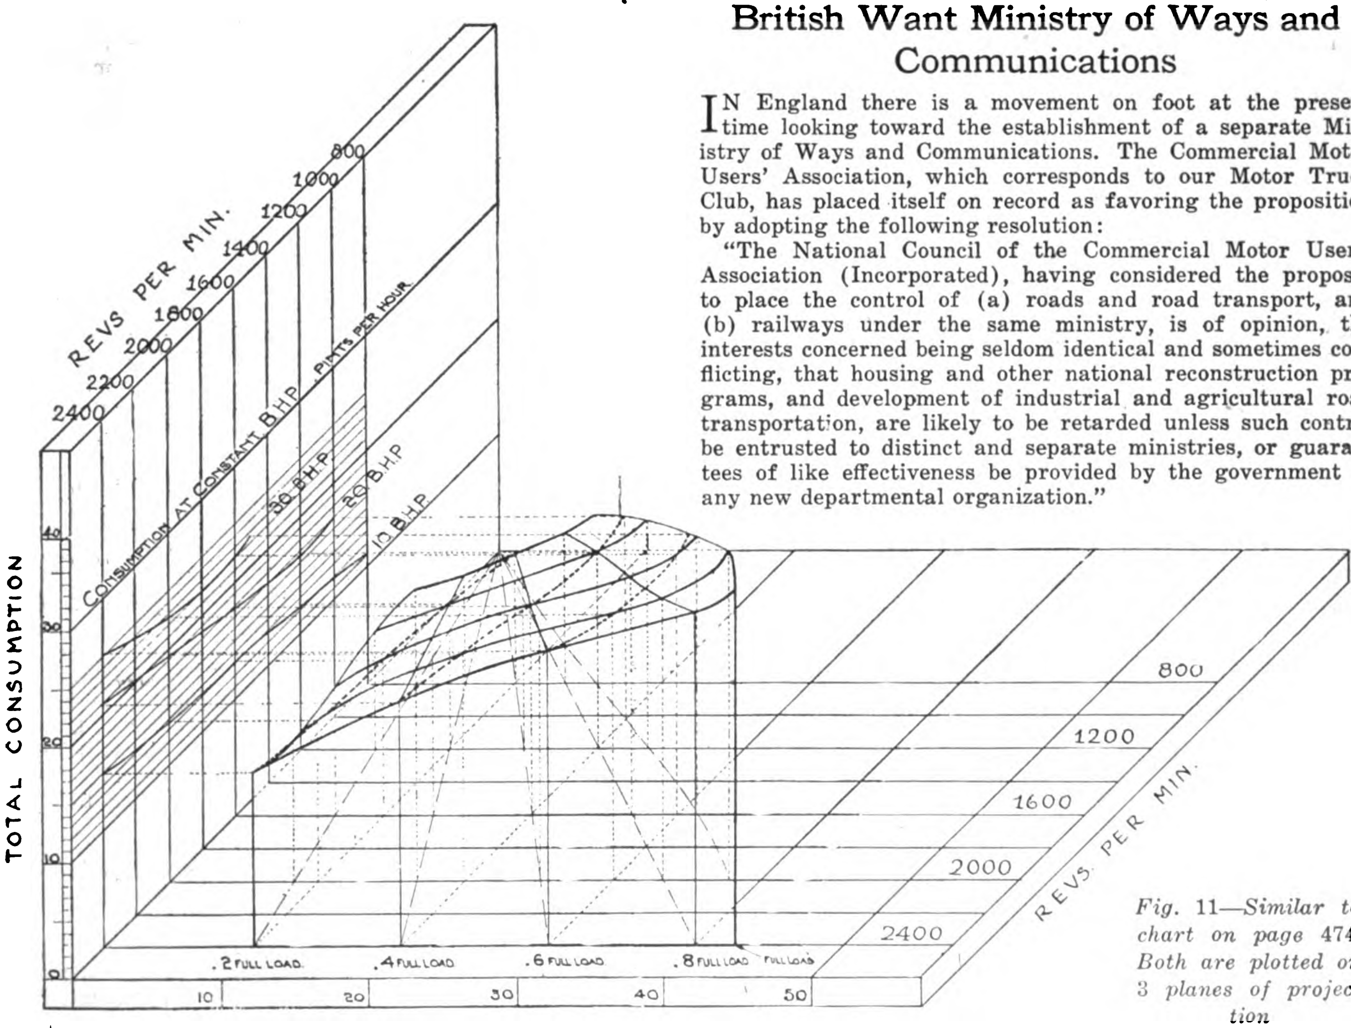

Fig. 11—Similar to chart on page 474. Both are plotted on 3 planes of projection

Labor's Representation in Plant Management the Immediate Problem

Workers' Demand for Voice in Factory Conditions Growing—Elective Representation Successful

By Harry Tipper

IT is evident from the discussions which are occurring in the various engineering and scientific associations and in the organizations of a less specialized character that the labor problem is receiving more study at the hands of the various industries than it has received at any other time. It is also evident from the tenor of these discussions that the futility of any attempts to solve the labor problem which do not take into account the lack of responsibility of the worker to his organization is becoming recognized more and more. The remarks which were contributed by Mr. Corless at the discussion of the Institute of Mining Engineers are indicative of this attitude:

"They have very little or no voice in governing themselves. They are parts of an organization, cogs in an economic machine which they do not fully understand, and in which they almost lose their identity—that is, their freedom for self-development. Somebody, somewhere, shapes the organization and sets it in motion, but the parts of the organization they see or the work they perform usually have little, if any, scientific or social meaning to them. Hence their spirit rebels. The human spirit, unless it has been utterly suppressed, is fortunately so constituted that it always rebels against any form of external authority in which it has no share, and which it does not intelligently grasp.

"Industrial peace will never be attained as long as capital and management assume the right to a final say on matters intimately affecting the welfare and even the self-respecting existence of a very numerous class, whose loyal co-operation is as essential to the success of every industrial enterprise as their own.

"Is it clearly recognized that we are at the beginning of a great transition period of industry? Do we realize that the autocracy of capital is coming to an end?"

All this emphasizes the necessity of those organization changes which have been discussed in AUTOMOTIVE INDUSTRIES and which look to the introduction of organization machinery which will give a definite share of the responsibility to the worker and throw open to the decision of the combined worker and governors of industry those matters which affect the welfare and even the existence in a self-respecting manner of the worker. The tendency of the events which have occurred since the armistice was declared in the relations between employers and workers in the various manufacturing countries is very easy to see.

There is a definite demand on the part of the worker for a larger control of the conditions under which he will work and for a larger share in the profits of the industry. This tendency has been noted many times in these articles, but it is so important a matter that it must be emphasized again in order that its significance will be thoroughly appreciated. In all the history of the relations of employers and employees as labor and capital since the beginning of the industrial revolution, the issues have never been drawn more clearly than they are drawn today, and the necessities of the case require more thorough and definite attention to the situation with a much closer study of the conditions and a much greater willingness to institute the organization changes which are necessary in order to provide the machinery for the solution of the present troubles.

No other system of organization has been found of any value in the development of industrial work up to the present, except the system which includes some form of representation by the worker and their proper methods of election in the body which has charge of the decision upon the hours of work, the rates of pay, holidays, welfare activities, and other matters that are concerned, under which the worker shall operate. It is interesting to note in this connection that the full plant of the Bethlehem Steel Corporation, which was mentioned in one of the previous articles, includes a complete organization for the joint operation of the worker and the management in all matters relating to the conditions of the worker, and in this respect takes in more detail than is definitely determined in most of such organization plans.

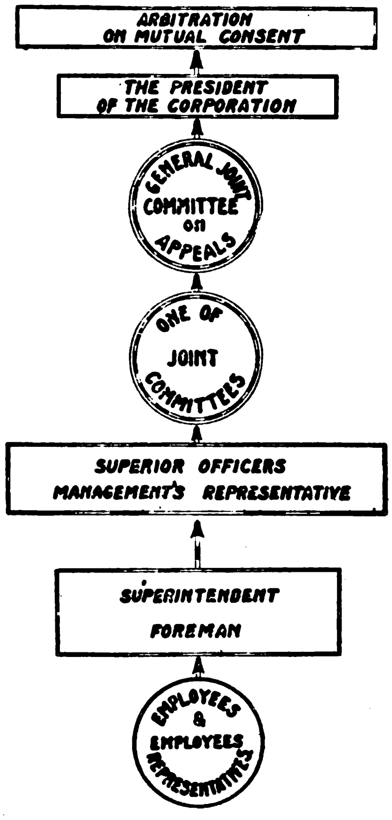

Chart illustrative of procedure in the prevention or adjustment of matters arising for settlement

This plan varies from the plans of the other steel companies which have been considered in this series in that it provides for a different representation based upon the size of the plant.

1. Representation shall be on the following basis:

Plants employing under 1500 employees: One representative for each 100 employees.

Plants employing 1500 to 10,000 employees: One representative for each 200 employees.

Plants employing over 10,000 employees: One representative for each 300 employees; provided, however, that in no case there shall be less than ten representatives.

Such adjustments as may be necessary to meet special cases shall be made.

2. For the purpose of applying the unit of representation, the plants should be subdivided according to departments and natural subdivisions. Wherever it is necessary to group a number of small departments in order to complete a unit of representation, regard shall be had to logical groupings and location.

3. Adjustments in units of representation shall be made in accordance with the recommendations of the Committee on Rules.

It has the usual provisions which have been accepted in large organizations for the qualifications of the representative and the elections. It provides for meetings of

the joint committees once every 2 months and for the representatives committees once every month. This frequency of meetings is an important point in the development of any such organization which was omitted from the earlier plans developed in some of the large steel companies, and which omission we noted at the time. The frequent meetings of these committees will do much to get them on a working order and to iron out the difficulties which must appear in the beginning of the organization work.

As we stated previously in considering this point, one of the important factors in this getting together of joint committees is the knowledge which will be gained by the different men of each other and of the respective personalities, opinions and desires. This knowledge itself will operate to clear away a great deal of the suspicion of misunderstanding which is the root of so much labor trouble, and this knowledge cannot be acquired unless the committees meet frequently.

The procedure for adjustment of personal grievances which is considered in this company has the same defect which has been found in a number of these plants. The number of steps which can be taken in order to settle such personal grievances are too many and the judicial procedure is much too involved to serve the purpose adequately. From observation, in a great many plants where some form of review is permitted for the settlement of personal grievances, the writer is convinced that it is not necessary to provide a great many steps of appeal in order to secure thorough satisfaction on these matters.

It is very important, however, that the procedure should not become involved to the delay in rendering a decision until the final result is an irritation in comparison with which the personal grievance is small, instead of a settlement of the matter which will remove the irritation.

Prompt Decisions Desirable

One of the great complaints insisted upon by the labor organization in Great Britain in respect of the Whitely Council which promises so much has been the difficulty of securing a decision from such councils, and the fact that between the action of the councils themselves and the references which had to be made to the central bodies where the council could not reach a decision, too long a time has been involved before the final decision of the final board of appeals could be issued. In the case of the review of a personal grievance, the important matter is to have a review board which by its composition will be above suspicion in the eyes of the worker; then to give that board sufficient leeway for the examination of witnesses and material involved in the case, so that it can render a decision promptly.

There is a tendency in a number of these cases in the judicial procedure of the industrial organization to follow the judicial procedure involved in the courts so as to provide a great many different lines of appeal, growing, finally, in this as in some other cases, out of the organization for the arbitration of the matter. It is not apparent that any good purpose will be served by this, and it may result in conditions of irritation which will destroy to some extent the good effect produced by the development of the representative system of organization. For those interested in the matter the chart presented by the Bethlehem Steel Corporation for both the representative committees and the legal procedure are shown in connection with this article.

During this time of adjustment there is an opportunity to stabilize the industrial establishment to avoid a great deal of turmoil which might ensue unless the adjustment is kept within orderly points, and to build a foundation which will permit the future stable growth of the industrial organization on a basis of efficiency not possible under present conditions. These organization developments which we have mentioned indicate the desire of many industrial establishments to place their business upon such a foundation, and the possibilities involved are important enough to merit the attention and study of every manufacturer.

There is a feeling among manufacturers that organization changes, looking to the removal of the continual warfare which exists between labor and capital, will be made at the expense of efficiency in production. There is no evidence which would indicate that this attitude is correct in any way. It arises from our old habit of considering the machine as the limiting point of capacity and looking to machine improvement for the development of more speed and efficiency in production.

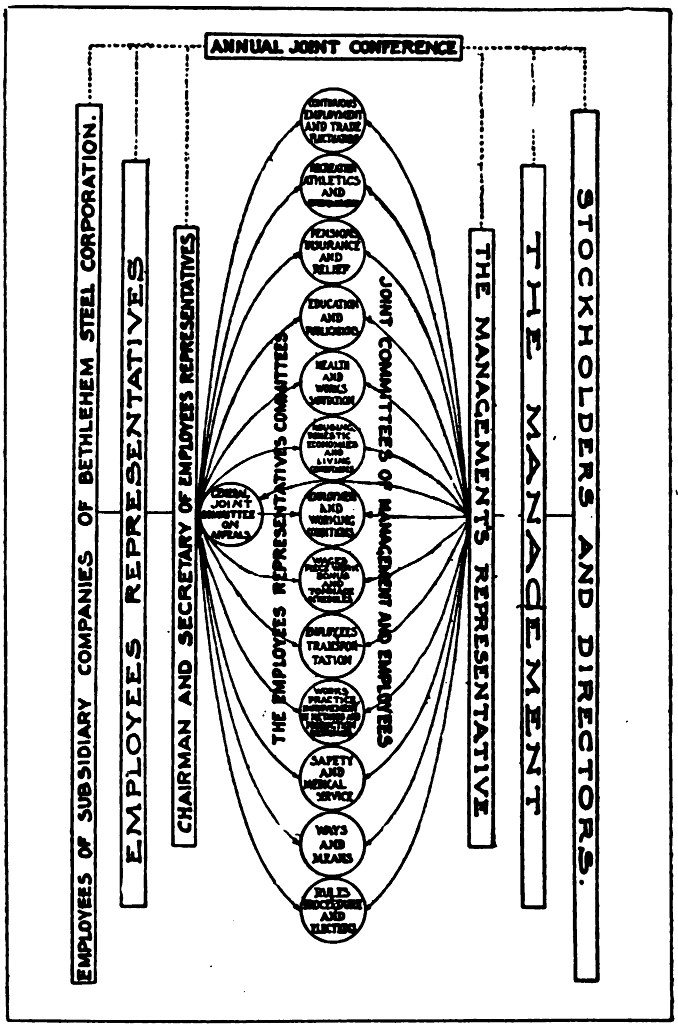

Chart illustrative of representation of employees of the Bethlehem Steel Corp. and subsidiary companies

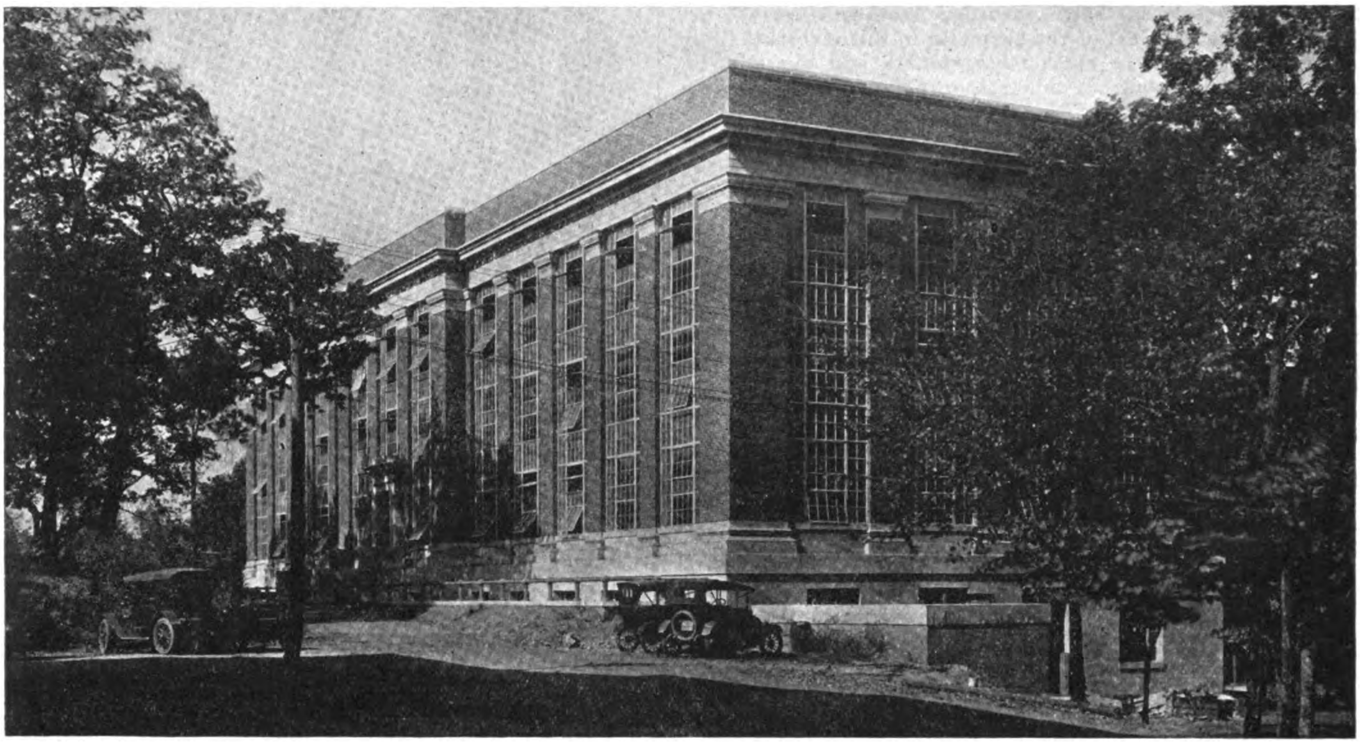
The history of the industrial development since the beginning of the modern factory system does not indicate that there has been any particular advance in a knowledge of the conditions which govern the personal efficiency of the individual. Its success and its tremendous development have been due almost entirely to the possibilities involved in massing men together for particular operations. In a very large measure, the benefit industrially from massing people together for particular operations has been due to the transfer of the skill from the worker to the machine so that the required efficiency of the individual was not so high, the period of training much shorter and the possibilities of error not so great.

Now that the factory system is thoroughly established and that improvements in machinery come more slowly, the necessity of an increase in the efficiency of the individual laborer is forced upon the manufacturer. Where organization changes have been instituted for several years, so that their effects have become visible, and these organization changes have been based upon sharing the responsibility for the labor condition with the employees, it has been found that the personal efficiency has increased a great deal so that it has been possible to secure a more effective production per dollar of wages outside of the saving secured by the lack of disorder and the elimination of strikes. It is necessary to know this so that the full economic value of such organization changes may be understood.

Industrial Tests by Bureau of Standards

Co-operated Closely During War with Military and Industrial Establishments—Wide Scope of Experiments and Tests—Wind Tunnel for Aviation—Standardization of Master Gages



Metallurgical Building, Bureau of Standards, Washington, D. C.

EDITOR'S NOTE—*Mr. Heldt has just completed an intimate study of war and other technical work performed by the Bureau of Standards at Washington. The following commences a series of articles, each separate and discussing, in detail, the tests, and results secured. The series will be published from week to week.*

FEW people, probably, have any conception of the great expansion during the war of the Bureau of Standards at Washington and of the present wide range of its work. No so many years ago there was little connection between this Government Bureau and the industries of the country. Everybody knew that the Bureau tested thermometers, calibrated weights and measures, and did similar work requiring an equipment of scientific apparatus and the necessary skilled personnel for handling it, but little was heard of co-operation between it and the great industries of the country.

During the period of the war, however, the Bureau has been co-operating closely with these industries and most of all with the automotive industries. In fact, all problems requiring scientific research or accurate tests that came up in connection with war activities were assigned to it.

Naturally the facilities of the Bureau soon proved inadequate to cope with the new work. Building construction has been going on all the time since the beginning of the war, and the personnel has been multiplied more than threefold.

It is an indication of the wide scope covered by standards that the following statement of the functions of the Bureau drawn up some years ago seems to fully cover its activities to-day: The development, construction, custody, and maintenance of reference and working standards and their intercomparison, improvement and application in science, engineering, industry and commerce.

The laboratories of the Bureau, which had been of great use to the nation in times of peace, proved of special importance during the war. Instruments, materials and supplies were on hand which were almost unobtainable elsewhere. Examples of the problems which were referred to the Bureau for solution are those which arose from the failure of the linen supply for aircraft construction and the lack of optical glass, which was formerly obtained exclusively from Germany. Other lines of activity of the Bureau during the past year that grew out of war requirements had to do with ship chronometers and with development work in connection with light alloys.

A very important branch of the Bureau during the past year has been that engaged in the standardization and testing of master gages used in the manufacture of munitions. The work done in this line by the Bureau has proven an important aid to the mechanical industries. Just previous to the declaration of the armistice the gage section of the Bureau had a staff of 140, and a special building has been erected for it. This section of the Bureau has a branch in New York City and maintains laboratories in Cleveland, Ohio, and Bridgeport, Conn. No less than 27,865 gages were tested during the last fiscal year.

Undoubtedly of most interest to the automotive industries is the work that was done in connection with aircraft development. As a matter of fact there has hardly been any line of development in connection with airplanes in which the Bureau has not co-operated in one way or another. This work was carried on under arrangements with the National Advisory Committee for Aeronautics. While the Interna-

tional Commission for Aircraft Standardization was sitting in Washington, much experimental work was done at the Bureau to help in the solution of the problems that confronted this commission. The work of the Bureau covered every detail of airplane design, materials, construction, efficiency of form, motor performance, efficiency of lubrication, carburetion, ignition, choice of fuel, propeller in plane performance, measuring instruments and the appliances required for control.

One of the most interesting investigations now in preparation is that of tests on airplane power plants in free flight. For this purpose six autographic test instruments have been designed, of which three have already been completed. These will automatically record the torque, engine speed, propeller thrust, plane speed, angle of attack and inclination to the horizon. All these factors will be recorded automatically while the plane is in flight, without the instruments requiring the least attention on the part of the pilot.

Much work has naturally been done during the past year by the section on aeronautical instruments, the staff of which was greatly enlarged. This section acted in an advisory capacity to the military authorities and also made numerous tests for them. Further researches are now being conducted with the object of improving the efficiency of altimeters. A special wind tunnel was built at the Bureau, operated by a 9-ft. propeller direct connected to a 100-hp. electric motor. In this wind tunnel it is possible to obtain air speeds up to 90 m.p.h. It serves to test the accuracy of aeronautical measuring instruments and to study the design of airplane parts, stabilizing control devices, the effect of stream lines, plane sections, etc.

The activities of the Bureau during the past year have been too many to be all enumerated here. Most of the work, of course, has been done either directly or indirectly for the Government. Now that peace has come again and that our industries are being directed into new channels, it is to be hoped that the facilities of this great national institution may be made available for the solution of problems confronting the various industries. Why should not our industries in times of peace look to the Bureau for the same assistance which our Government received from it in time of war?

Tests of Airplane Radiators

An Experimental Study by the Bureau of Standards Conducted at the Request of the National Advisory Committee for Aeronautics, Bearing on Head Resistance, Resistance to Water Flow and Weight, All in Relation to Heat Energy Dissipated

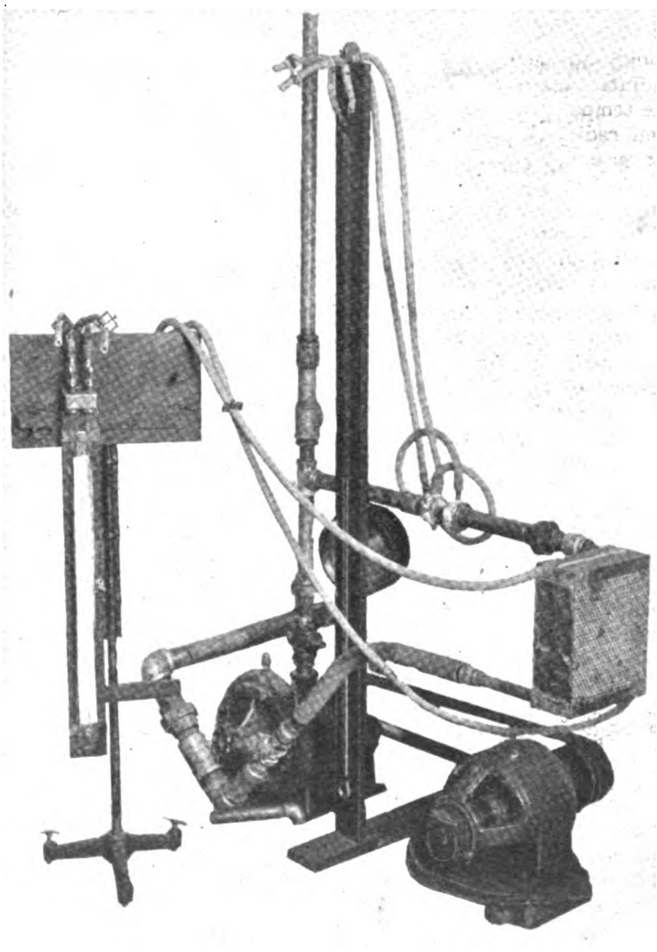
By P. M. Heldt

IF a number of automobile radiators were to be compared on a strictly technical basis, leaving out of account such factors as cost of construction and freedom from tendency to develop leaks, it would probably be agreed that the proper basis would be the amount of heat dispersed per unit of time per unit of radiator weight. In an automobile any unnecessary weight is a detriment, and if a radiator construction can be found which will permit of reducing the weight without loss of cooling qualities, it is an improvement over existing types.

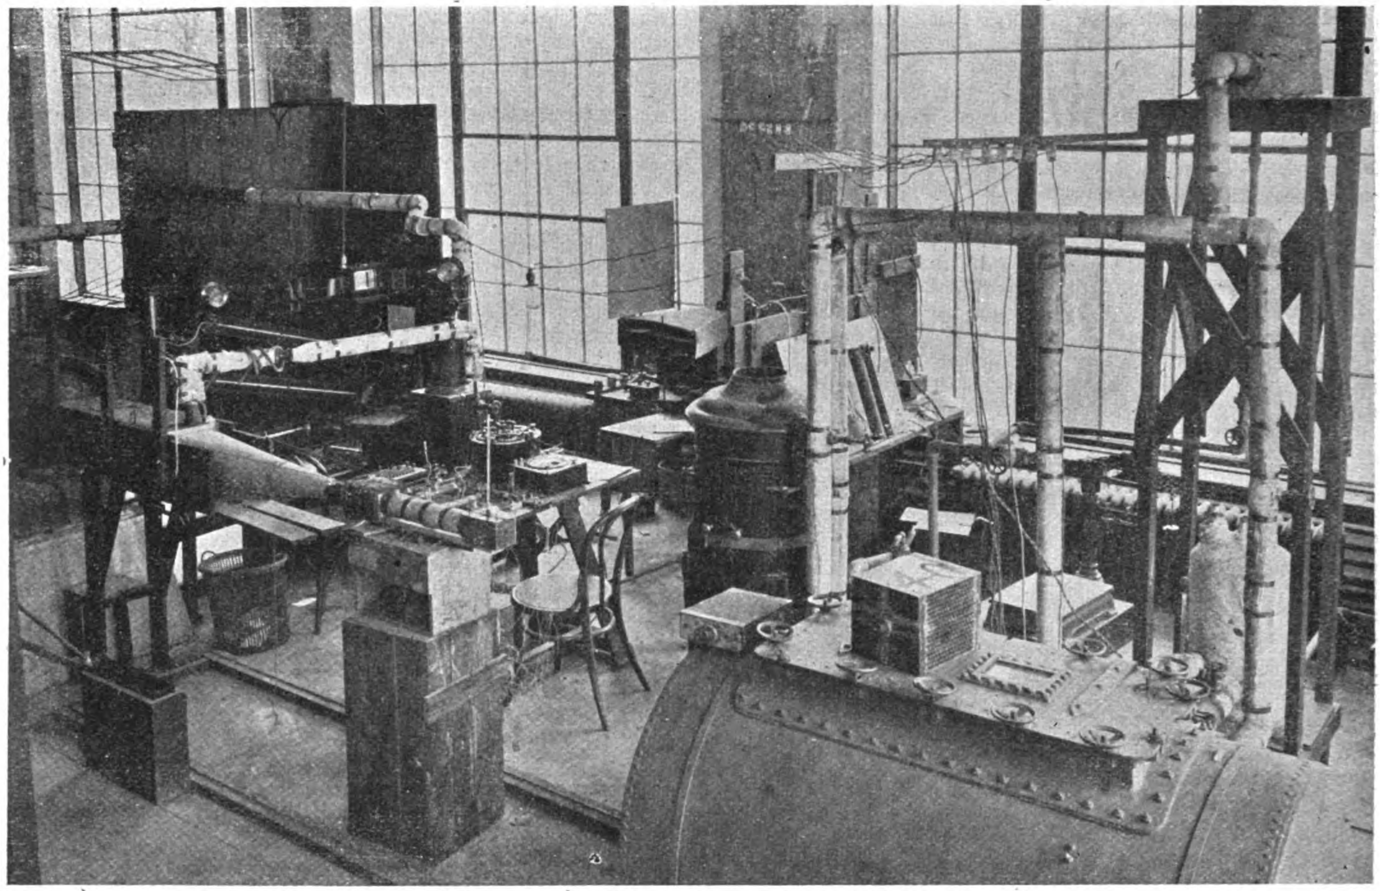
In aircraft work unnecessary weight is far more objectionable than in automobiles, for the reason that the horsepower expenditure in transporting, say, 100 lb. of weight in an airplane at the usual speed is incomparably greater than that expended in transporting the same weight in an automobile. Yet lightness is not the most important characteristic of an airplane radiator. What is required most is a minimum head resistance per unit of heat dissipated per unit of time. The radiator cannot be placed inside the airplane body or in some other location where it merely absorbs the carrying capacity of the plane, but must be located where it is fully exposed to the wind created by the plane's motion, hence it adds materially to the head resistance of the machine, and, other conditions being the same, that design of airplane radiator is best which for a given rate of heat dissipation creates the least additional head resistance.

Test Apparatus Used

At the Bureau of Standards in Washington quite elaborate apparatus has been installed with the object of testing samples of radiator cores with respect to their ability to disperse heat, and their head resistance. These samples, which are made up in uniform sections 8 in. square, are being tested in a vacuum chamber in which the air pressure can be reduced to that corresponding to different altitudes of flight. The air is circulated through the specimen by means of a blower mounted in one end of the chamber. The vacuum chamber is made of boiler plate, with one concave and one convex head. The specimen is placed inside of a wind tunnel made up of 1-in. planking, of square cross section with pyra-



Apparatus used to measure pressure necessary to produce water flow through radiator core



View of the radiator test laboratory

midal approaches at each end. On each side of the specimen radiator are located thermo couple grids by means of which the temperature of the air on entering and leaving the specimen radiator may be accurately measured. The quantity of air passing through the radiator in unit time, or, in other words, the rate of air flow through the specimen, is measured by means of a Thomas meter or a grid of pitot tubes in front of the specimen.

Through the specimen radiator is circulated either hot water or steam from a heating boiler close by. It has been found that when the rate of circulation through the radiator exceeds a certain value, the heat dispersal is practically the same whether water or steam is being circulated. The amount of heat given off by the specimen radiator can be measured in two diffrent ways—by measuring the rate of water flow through the radiator and the drop in temperature of the water, and by measuring the rate of air flow through the radiator and the temperature rise of the air—and the two results usually check to within 1 per cent. The air that is passed through the radiator for the purpose of abstracting heat from it is circulated only within the vacuum chamber. It is drawn through the central wind tunnel by the blower located at one end of the chamber and returns through the outer portion of the chamber where it has to pass through the cells of a cooling radiator through which cold water is circulated. In this vacuum chamber air speeds up to 70 m.p.h. can be obtained. For higher air speeds, up to 120 m.p.h. the atmosphere test chamber is used, and head resistance measurements are made in the large wind tunnel of the Bureau, where air speeds up to 90 m.p.h. can be obtained.

There are glass windows in the top and in one side of the vacuum chamber through which the specimen and other apparatus within the chamber can be observed while a test is on.

A very careful study of the problems connected with aircraft radiator design has been made by the Bureau of Standards and several reports on this subject have been made to the National Advisory Committee for Aeronautics. In its study of the problem the staff of the Bureau had the advantage of access to reports on the same subject made earlier by scientific committees in Allied countries.

There are several distinct types of radiator core construction. Cores in which the air passages are of substantially tubular form are called cellular radiators. The true honeycomb core is a cellular core in which the water can circulate freely in all directions on all sides of each air tube. Water tube cores are cores in which the tubes form the water passages and the air passages are formed by the spaces between these water tubes. In one type of water tube core sheet metal fins are secured to the water tubes and extend out into the air passages to give additional indirect cooling surface, but this type has proved of little value in aeronautic work. Another type, consisting of very flat tubes set edgewise to the air current, has given promise of great value for planes of very high speed.

Definition of Terms

In a radiator the air flow and the water flow are always at right angles to each other. The dimension of the core parallel to the direction of water flow is called its length; that parallel to the direction of air flow, its depth, and that perpendicular to both is called the width of the core. The frontal area is the total area of the core perpendicular to the direction of air flow. While there are three steps in the transfer of heat from the water in the radiator to the air passing through it, it is found that the transfer of heat from the metal of the air tubes to the air is the most important and limits the capacity of the radiator, so that the surface area of the air tubes, which is called the "cooling surface," is the most important factor.

A distinction must be made between direct cooling surface, which is in contact on one side with water and on the other side with air, and indirect cooling surface, which is not in direct contact with the water but to which the heat must flow through a considerable length of metal. The temperature of direct cooling surface is substantially the same as that of the water in contact with it, but owing to the length of the

path of heat flow from the water to the indirect cooling surface, the latter is of considerably lower temperature than the water and the rate of heat dispersal is much less from indirect than from direct cooling surface. In some types of core, pockets are formed in the water tube walls in which there is very little circulation of water, and the Bureau of Standards regards such surface as indirect cooling surface.

Factors Involved

The following is taken from an anlysis made by the Bureau of Standards of the properties which determine the suitability of a particular radiator for use under aircraft conditions:

1—The cooling capacity must be equal to the heat to be dissipated under the worst conditions, that is, when the plane is climbing at its maximum rate from the ground in hot weather. It must also be possible to control the cooling capacity so that the water temperature in the engine jackets will not fall below a predetermined value under conditions of most rapid cooling, as when diving or when flying at high altitudes in cold weather.

2—The head resistance of the radiator has an important influence on the total amount of power required for propelling the plane and is a factor in determining its aerodynamical properties.

3—Another important factor is the combined weight of the radiator and the water contained by it. This affects the balance of the plane as well as the power required to carry the radiator.

4—If the head resistance of the radiator is known, the power required to overcome this resistance at any given speed may be readily calculated, as may the power required to carry the radiator, which is simply that proportion of the total brake horsepower usefully expended which is represented by the ratio of the radiator weight to the total loaded weight of the plane.

5—The pressure required to force the water through the radiator is a factor.

6—It is desirable to have a simple means of comparing the relative values of different radiator constructions. It has already been stated that the criterion of radiator merit is that it shall absorb the least power for the given rate of heat dispersal. As it is possible to express the heat dispersal in horsepower, the ratio of heat dispersal to energy absorption due to the head resistance and weight of the radiator will be a simple number which will be the same irrespective of the units employed. This figure for any particular radiator is called its figure of merit. The best airplane radiator for "free air mounting" is that having the highest figure of merit.

In making a study of different core constructions, the Bureau took note of the following features:

1—The form of the air and water passages.

2—The depth of the core.

3—Quality and thickness of the metal.

4—Weight of the core empty and of the water contained.

5—The free area of the air tubes, defined as the percentage of the total frontal area occupied by the free cross section of the air tubes.

6—The hydraulic radius of the air tubes, that is the area of the tubes divided by their combined perimeter.*

7—The ratio of length of air tube (depth of core) to hydraulic radius.

8—The cooling surface in square feet per square foot of frontal area.

9—The proportions of direct and indirect cooling surface.

10—The dimension of the water tubes, including the length in the direction of flow for a section of the core 1 ft. long, the width of the tubes, the thickness and the hydraulic radius, all expressed in inches.

11—The cross sectional area of the water tubes normal to the direction of flow. With uniform tubes this is equal to the area of a single tube normal to the direction of flow, multipled by the number of tubes per foot of width.

Factors in Radiator Operation

Following is an enumeration of the factors entering into the operation of a radiator:

1—The mass flow of air through the core, which may be defined as the rate of flow, in pounds per second through a unit of frontal area.

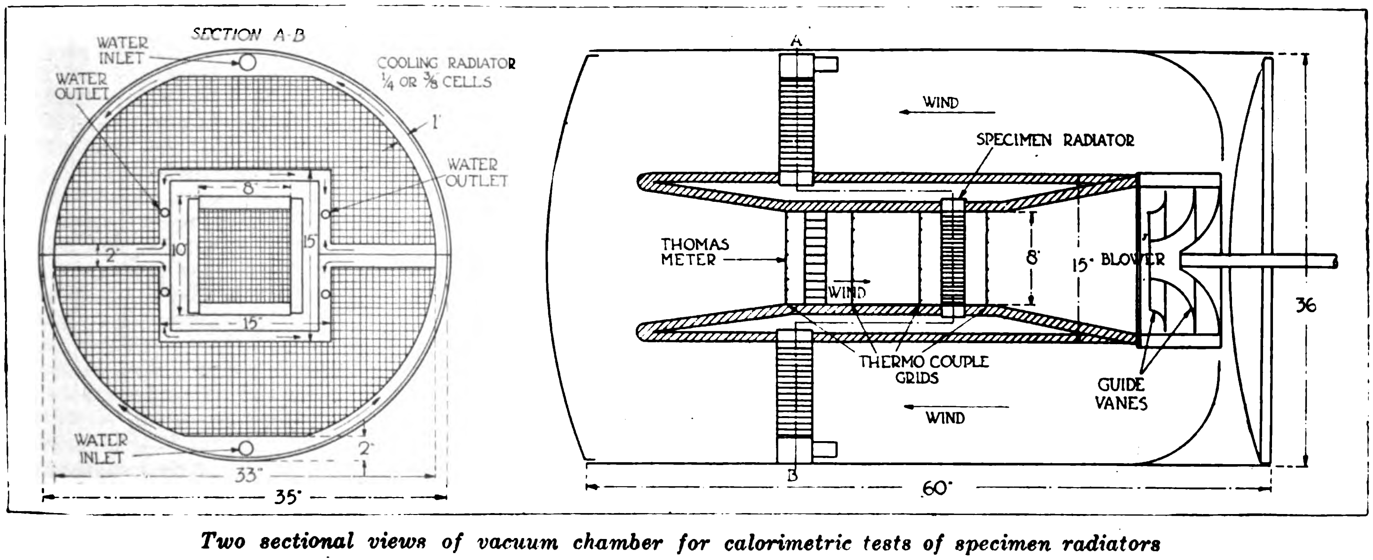
2—The temperature difference between the air and the water. This is taken as the difference between the arithmetic mean of the entering and exit temperatures of the water and the temperature of the entering air, in degrees Fahrenheit. It is pointed out in this connection that for the highest degree of accuracy the logarithmic mean of the water temperature should be used, but as there is little difference between the logarithmic and arithmetic mean, the latter is used for the sake of simplicity.

3—The air density, which is taken at 0.075 lb. per cubic foot at ground level.

4—The flow of water through the core, in gallons per minute.

5—The nature of air and water flow through the core, reference being made particularly to the difference between stream line and turbulent flow. When the flow is turbulent the exchange of heat between the fluid and the surrounding wall is much more rapid than when the flow is of a stream line character. Turbulent flow is obtained at all speeds met with in airplane radiators. The speeds required to produce it are smaller the larger the diameter of the tube. When a fluid flows around an obstruction not conforming to the

*Since the cooling surface of a plain cellular radiator is very nearly equal to the depth multiplied by the perimeter of the air tubes, the hydraulic radius of the air tubes for such a core may be obtained by dividing the total volume of the air tubes, i.e., the free area multiplied by the depth, by the total cooling surface. This has the advantage of being a quantity which can be found for noncellular types of radiator.



Two sectional views of vacuum chamber for calorimetric tests of specimen radiators

stream line form, turbulent flow is produced even at low velocities, this being referred to as artificial turbulence.

In the work of the Bureau of Standards on radiator cores, the properties of the cores were defined as follows:

1—The energy dissipated is expressed in horsepower per square foot of frontal core area and for a standard temperature difference of 100 deg. Fahr. It is intended that the rate of water flow when this figure is attained should be high enough to produce turbulence.

2—The weight of the core in pounds per square foot of frontal area, both empty and with the water required to fill that section of the core.

3—The head resistance of the core, which may be defined as the force which would be exerted on the radiator if it were supported in a free air stream which produces the given mass flow.

4—The mass flow of air through the core when supported in a free air stream, which for all ordinary types of core has been shown to be proportional to the free air speed to which the core is subjected, so that if the proportionality factor has been once determined the mass flow for any free air speed, in pounds per second per square foot of frontal core area, may be readily found. This proportionality factor, which is based on air density of 0.075 lb. per cubic foot, is called the mass flow factor of the core.

5—The energy absorbed by the core under free air conditions in horsepower per square foot of frontal area.

6—The figure of merit of the core, which is obtained as described for a radiator.

Head Resistance Problems

Among the problems which it was proposed to study by the Bureau of Standards are the effect of the nature of the cooling surface and the effect of depth on the head resistance of a core. It is pointed out that the head resistance is composed of two factors, namely, the force due to impact on the front and rear areas of the metal and the effect of skin friction in the tubes which exerts a drag on the core. This latter effect may be obtained by measuring the pressure drop within the tube over a portion of its length. This factor alone will vary with the depth of the core if the entrance and exit of the tubes are constant, and so the head resistance of the core as a function of the mass flow can be computed if the resistance of one depth of core and the drop through the tubes per unit length are obtained.

Procedure of Tests

In the experimental work that has been done, a large number of standard specimens of various types of core obtained from manufacturers were submitted to 5 series of measurements:

1—Measurements of the physical dimensions of the specimens, the average value for the entire specimen being obtained as accurately as possible.

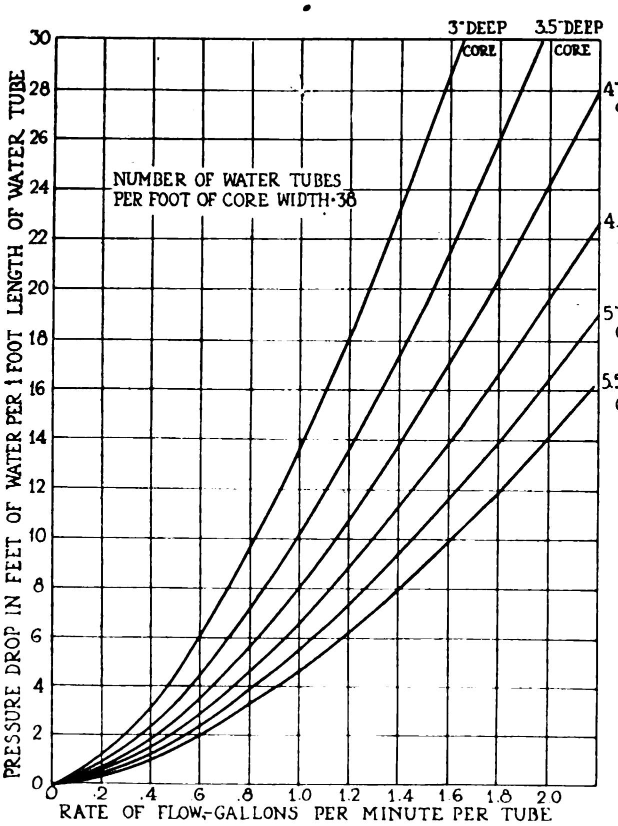
2—Measurements of the energy dissipated for various mass flows and under various conditions of air density; rate of water flow and temperature. These experiments were made in tunnels in which all the air flowing through the tunnel is forced through the tubes of the specimen, so that the mass flow is actually measured.

3—Measurements of the mass flow of air through the core under free air conditions were made in the 54 in. wind tunnel of the bureau by means of a specially designed air venturi.

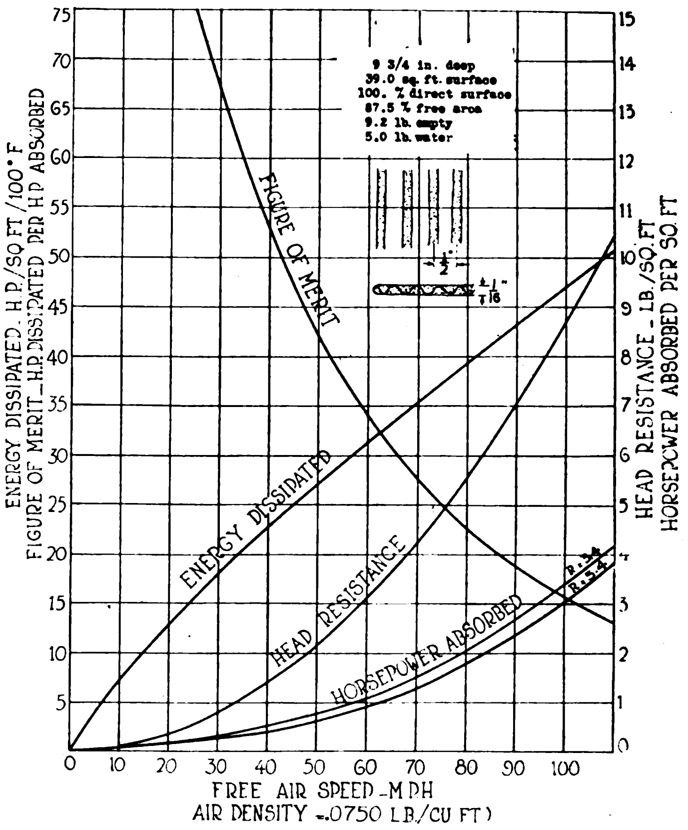
4—Head resistance was measured also in the large wind tunnel by mounting the specimen on the arm of a balance.

5—Some work has been done on the pressure required to produce water flow through the core, though the opinion prevails that this test should be made on complete radiators.

The mass flow through a core supported in free air can be obtained from tests made in a wind tunnel, but if the flow of air through or around the core is in any way obstructed, it is necessary to study the performance to some extent in position on a plane in flight. The simplest method of determining the thermal properties of a radiator in any location is to determine the mass flow through various parts of the core, as with this data at hand the heat dissipated can be calculated from laboratory tests. A plan for measuring the mass flow through a radiator core in flight has been laid out but has not yet been carried out. Another problem to be studied is the amount of heat per brake horsepower of the engine that must be dissipated in flight, and the effect of cowling of the engine on this factor.



Pressure required to force water through core at different rates



Curves showing results obtained with a flat tubular radiator core

The results obtained in the experimental work were expressed in the following form:

1—A table of core characteristics.

2—Curves showing the heat dissipated, the head resistance of the core, the power absorbed with an average lift-drift ratio for the plane, and the figure of merit under given assumptions at various mass flows of air, together with an auxiliary scale showing the equivalent free air speed, that is the free air speed which, striking the core unobstructed, would cause the same mass flow and consequently the same dissipation of heat, head resistance and power absorption.

3—General relations showing how the properties of the core vary when the conditions of use are changed.

4—Data showing the relation between the conditions under which the radiator is to operate on the plane and the conditions under which the parts of the core operate.

Method of Using Results

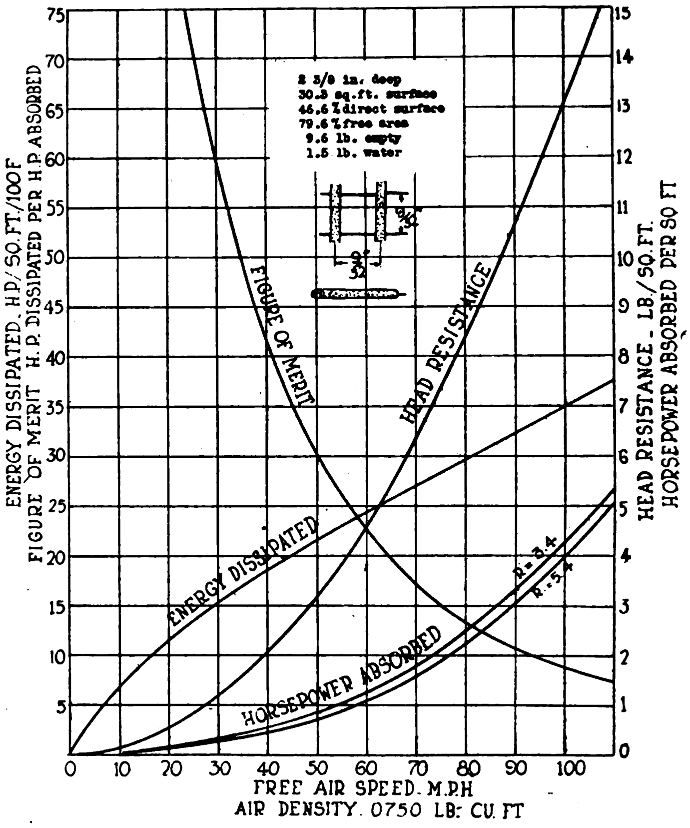
By means of a few simple rules the experimental results can be applied to a predetermination of the performance of an actual radiator on a plane. In the first place, the energy dissipated by a core of any size is directly proportional to the frontal area. In applying this rule the mean temperature of the water in the whole radiator must be used in computing the temperature difference.

The weight of the core of a radiator is directly proportional to the frontal area, but, of course, the weight of the water tanks and of the water they contain is in some cases a considerable factor. Experiments have shown that the resistance of a radiator core is substantially proportional to its frontal area. The effect of the tanks must be allowed for, as must also the effect of location. The power absorbed by the core is also directly proportional to the frontal area.

The pressure necessary to produce water flow is given not for a square foot of frontal area but for a section of core 1 ft. wide and 1 ft. long; in other words, it is the pressure per foot of length necessary to produce the given flow per foot of width. It is then necessary to divide the total flow desired by the width of the core to obtain the flow per foot of width, in order to be able to find from the data the pressure drop per foot of length, and then multiply this by the total length of the core to obtain the total pressure drop. When the widths of different parts of the radiator are different, and when there are intermediate tanks, as around the propeller hub, corrections must be made.

The figure of merit of a radiator is computed from the power absorbed and the heat energy dissipated. If the effect of the tanks is neglected the figure of merit depends on the core structure and on the location on the plane, but not on the frontal area.

For a radiator to be mounted in a free air position on the plane, so that the effect of location on the properties of the radiator is negligible, the figure of merit for the core is the fundamental criterion. When a radiator is placed in an inclosed position, as in the nose of the fuselage, the mass flow of air through it will be less. In general the mass flow will be decreased less relatively in a radiator of high resistance than in one with an open type of core. For given mass flow the resistance of a radiator in an inclosed position appears to be considerably greater than under free air conditions. Similarly, the absorption of power is greater and the figure of merit lower. There has been a tendency recently to place the radiator in the plane of the wing. In that case the air flows upward through the core, decreasing the lift of the wing but producing little effect on the resistance. It is believed that for this mounting a core of very compact structure would be preferable.



Test results obtained from a cellular effect core

Spring Tires Used by German Army

SINCE practically all imports of rubber into the Central Empires ceased with the outbreak of war in 1914, and mechanical vehicles are used very intensively in modern warfare, it is no wonder that rubber was a very scarce article in Germany toward the end of the struggle. It appears that synthetic rubber is now a regular article of manufacture, and a recent report has it that a works at Leverkusen turns out 165 tons of this product a month, but it seems this finds application chiefly for insulating purposes, for which it is said to be superior to natural rubber.

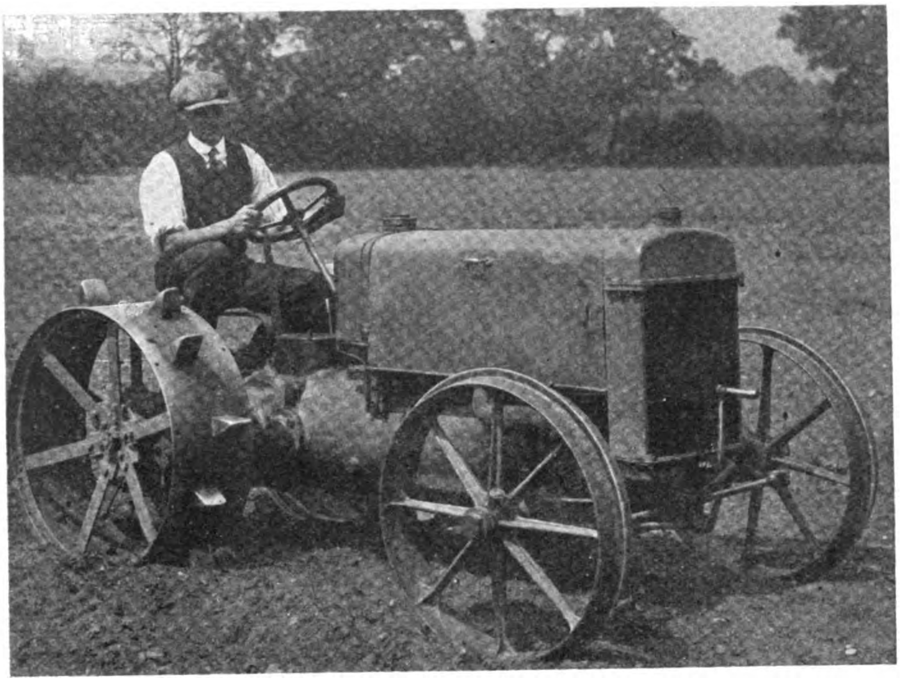
At any rate, vehicles attached to the German army on the Western Front were fitted with a combination steel spring and leather tire and a section of such a tire has been sent to the B. F. Goodrich company by Capt. August Barth, who is serving in France with the 303d Repair Unit of the Motor Transport Corps. It was from a vehicle of the personal messenger and body guard of Prince Eitel Frederick, it is claimed.

In his letter Captain Barth said this type of tire was used extensively by the Germans and that it proved fairly satisfactory when the roads were good and the rate of speed moderate. It was practically useless when excessive speeds were called for because the radially mounted spiral springs became easily misplaced when turning corners or when obstacles were encountered. The spring tire sent by Captain Barth contained three plies of spring steel on the outer band on which was bolted a heavy strip of leather.

AN active propaganda in favor of road improvement is being carried on in England by the Automobile Association and Motor Union. Just previous to the recent Parliamentary election the organization circularized candidates to secure their support for legislation for the reconstruction of roads upon lines suited to modern traffic, for the assurance of a sufficient supply of fuel at a reasonable price, together with the encouragement of home-produced fuel, and an up-to-date Motor Car Bill under recognized auspices. Of the 341 replies sent 276 were in entire agreement and none were hostile.

The Austin Farm Tractor

A British Tractor on Fordson Lines Which It Is Anticipated Will Sell at $1,000



A new British tractor on Fordson lines manufactured by the Austin Motor Co., Ltd., Birmingham

LONDON, ENGLAND, Feb. 4.—The frameless form of tractor continues to find favor among European manufacturers. The model shown is being introduced by the Austin Motor Co. at Northfield, Birmingham.

The trunk or tubular casing is made up of four cast-metal sections, flanged and bolted together. Of these the foremost section is a transverse bracket which carries the radiator on a trunnion about which the front axle beam is free to oscillate, but is held against a fore and aft displacement. The second, third and fourth sections of the casing compose the engine and clutch, change-speed gear, and axle-gear units. The gross weight is under 2912 lb., but a large driving wheel of 3½ ft. diameter by 10 in. wide is being substituted for the present dimensions of 3 ft. by 14 in.; it is anticipated that the gross weight will exceed slightly that tare.

Engine with Four Cylinders En Bloc

The engine has four cylinders *en bloc*, with a detachable head which covers the valves, the usual protruding side pockets being avoided. The cooling is by natural or thermal circulation through large bore pipes. The bore and stroke of the cylinders and pistons measure 3¾ in. x 5 in. A crankshaft speed of 1200 r.p.m. is the normal rate.

The engine is started on gasoline and then runs on kerosene, a Zenith carbureter being used for both fuels, with a change-over valve interposed in the fuel pipe line. The output at normal speed is about 25 hp. The engine shaft has the unique feature among tractor engines with *en bloc* cylinders of five main journals, with suitable provision for their adequate and direct pressure-fed lubrication by a pump. Ignition is by a high-tension magneto with fixed firing point.

The power is transmitted through a pressed-steel cone clutch having a self-cushioning engagement through the medium of interposed under-periphery springs. The cone is faced with asbestos fabric, which can be removed in a short time without dismantling the clutch. The transmission is through a bevel-geared first-motion shaft, which also carries a belt pulley on its end, which is carried through the casing. This gearing is so arranged that at normal engine speed the pulley shaft speed is about 330 revolutions per minute. It is intended to provide three speed changes for the driving wheels; at present there are but two rates through a second motion shaft and a large spur-gear wheel in the axle casing, the latter gear wheel combining the differential or axle balance mechanism.

The driving wheels are of the built-up light traction engine pattern, and are secured to the axle ends by splines of integral feather-keys. The main journals revolve about Timken roller bearings, and the rear wheel hubs and the fore axle have rubber buffers for cushioning shocks. The fore end of the tractor casing is suspended on coil springs; the rear portion is springless, as is usual with tractors designed for land work. The steering lay-out follows the Ackermann system, with the cross bar placed in front of the axle beam. The price first mentioned is $1,000, and its listed capacity is a two-furrow plough.

A LARGE bombing machine built at the Farman aircraft works in France, which has been named the Goliath, is being adapted for use in passenger service. Seats have been installed running the length of the fuselage, large lateral windows have been fitted for sight-seeing, and a flight to London on this big twin-motored machine is contemplated as soon as fine weather sets in. The two Salmson engines give 540 hp., and the anticipated speed is in the neighborhood of 90 m.p.h., with a relatively slow landing speed. Internal heating apparatus has been provided, and on a regular run the machine should carry 30 passengers with comfort.

SOME experiments bearing on the importance of properly focusing bulbs in headlamps are reported in the *General Electric Review*. With a 10-in. headlamp and 21 candlepower Mazda lamp, it was found that the beam of light was reduced to 31 per cent, if the filament was 1/16 in. out of focus, to 18 per cent with ⅛ in. error, and was only 4 per cent of its proper power if the filament was misplaced to the extent of ¼ in.

Automotive Industry Just Stripped for Action When Germany Quit

Contributed Many Unusual Products and Heavily of Employees and Executives to Uniformed and Civilian Service—Some Interesting Sidelights

By J. Edward Schipper

THROUGHOUT the country manufacturers in the automotive industry are ruefully surveying great rows of machinery and great piles of shell blanks and other raw materials stored in various parts of their factories. Hundreds of accountants are busy making up claims to be presented for adjustment and hundreds of millions of dollars are temporarily tied up awaiting approval and payment of the claims. Working its way through the country is the feeling that the Kaiser quit just about a year before he should have, in order to see what this country could do after it had fully gotten into action.

The final chapters are now being written on the participation of the automotive industry in the government war program. The books are being closed on what has been the most eventful two years the industry has ever spent, and while the readjustment period is a difficult one, it is in the main being handled efficiently by the manufacturers who are endeavoring to get back into production. It must be confessed, however, that the industry is still sadly torn up and disarranged because the order of the government to be on 100 per cent war work by the first of January, 1919, meant the tearing out of all the production methods and machinery in every plant which was not so fortunate as to secure orders for its standard products. New government machinery had to take the place of the production machinery formerly employed. Generally, the machinery used in automobile manufacture was too light for the heavier products, such as shells used in government work, and consequently many shops did not have a machine standing in its original place. With the financial backing of the government, however, and with everything cleared out of the way for the purpose of winning the war, it was much easier to get into war work than it was to get out of it. Former sources of supply are just as disrupted as the factories, so that it is impossible to start manufacturing automobiles in many instances without the threat of a much unbalanced inventory, owing to the inability of parts makers to deliver on schedule.

This leads back to the interesting question of what did our industry do during the war. What was accomplished which merited this disruption and confusion? The history of the larger companies has become more or less well known where the work has been of a spectacular nature, but hundreds of smaller concerns which made every sacrifice to do their bit, and which in hundreds of instances are now threatened with financial disaster because of this work, have been passed by unnoticed.

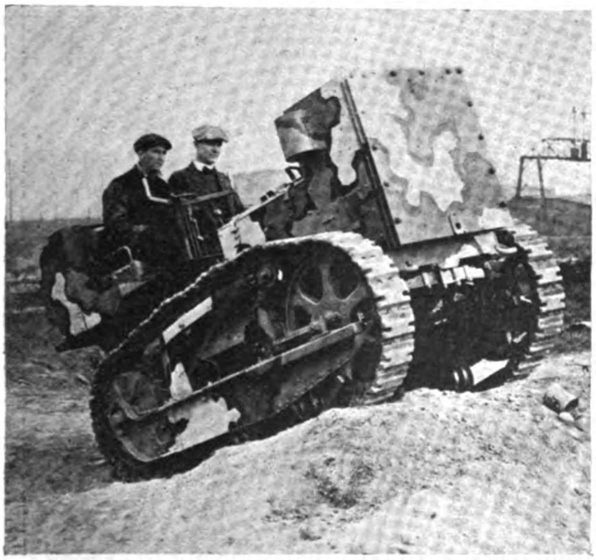
What the Industry Did

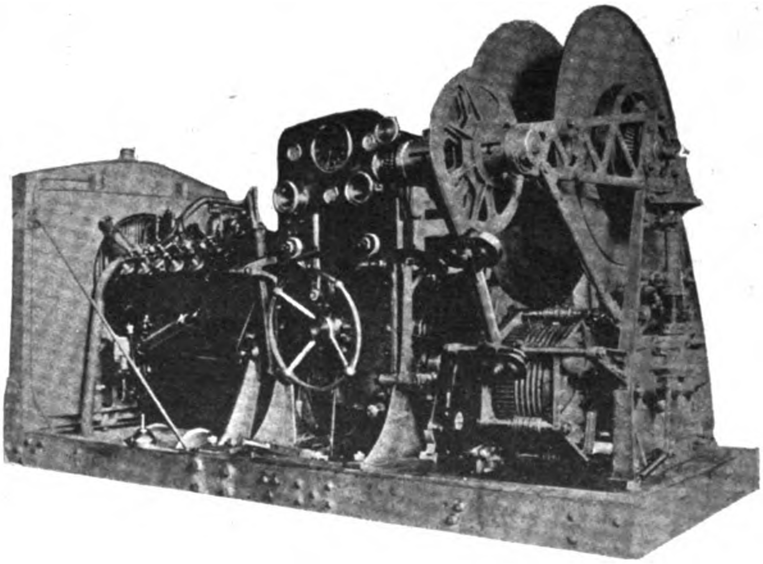
There is no more interesting phase in the study of what the automotive industry did during the war than the survey of the products which the different factories made and which in many instances were far different from anything that they had ever previously attempted. For instance, we find the Willys-Overland Co. making the OX-5 training plane engines, 77-mm. gun carriages, 8-in. shells, Liberty eight engines, Liberty twelve engines, Mark III adapters, types A and B lifting plugs, Sunbeam airplane engines and military tractors for the British government, and a miscellaneous assortment of smaller parts.

Packard and Ford, as is well known, did a tremendous work in the development and manufacture of the Liberty aircraft engine. In addition, the Packard army trucks left in a continuous stream during the entire period of their participation in the war. Besides, there were militor tractors and many small gun forgings made at the Packard factory.

Maxwell made 6-ton trucks, Ford was just starting big production on a small two-man tank, and Locomobile made the first of the Mark VIII 35-ton tanks, besides great numbers of Riker trucks.

The Hudson company made the transmissions for the 6-ton





Left—2½-ton artillery tractor driven by a Cadillac eight-cylinder engine. Right—Eight-cylinder Cadillac engine being used as a motive power of a balloon winch to lower observation balloons

General view of the larger of two machine rooms at the Willys-Overland Co. Building and equipment especially designed and built for 8-in. shell production

tanks. It also had a contract for making Nash Quad trucks, and the company was shortly to engage in the manufacture of the higher speed types of 6-ton trucks, equipped with its own Super Six engine.

When the armistice was signed the Olds Motor Works was in the midst of diverting its entire facilities, including both plant and organization, to Liberty engine work on an extensive scale. Large factory additions were under construction, and between a million and a million and a half dollars' worth of equipment had been ordered, all with a view of taking on about two thousand workmen in addition to the regular force of 1500. It was expected that this concern would be in production during the early part of January. Work was stopped with the signing of the armistice, and by now the plant is nearly up to normal production.

Dodge Bros. went into artillery manufacture. Shortly after war was declared the United States went into the manufacture of the 155-mm. howitzer and the 155-mm. Filloux rifle. These guns required a hydraulic recoil or recuperating device, but as none of this mechanism had ever been built in America, the problem involved the gigantic task of not only constructing a special plant, but the designing and making of special machinery and tools. Dodge Bros. put up a plant valued at $10,000,000 and for months have been shipping these vitally important parts. These recoils permit the gun to return to normal in 13 seconds when fired at an angle of 45 deg. They are made from billets of steel, that for the rifle weighing 7800 lb.

The Hupp Motor Car Corp. made tools and gauges for subcontractors, ordnance shell parts, tank parts, engines, light trucks and heavy truck parts, and this concern is stated to have been just about ready to take on a wide variety of additional work.

No one would ever picture the Haynes Automobile Co. building Buda engines or Quad transmissions, and yet both these products were on the Haynes program of war work.

The smaller production companies, such as Harroun, turned out thousands of the 155-mm. long-range high-explosive shells. The Templar Co. of Cleveland made the same type of shell; the Dort company, in place of the small touring car and roadster, turned out in quantities of perhaps 15,000 a year, turned its attention to cargo trailers and then to the G. M. C. ¾-ton truck, kitchen trailers and special truck bodies. Reo made army tractors.

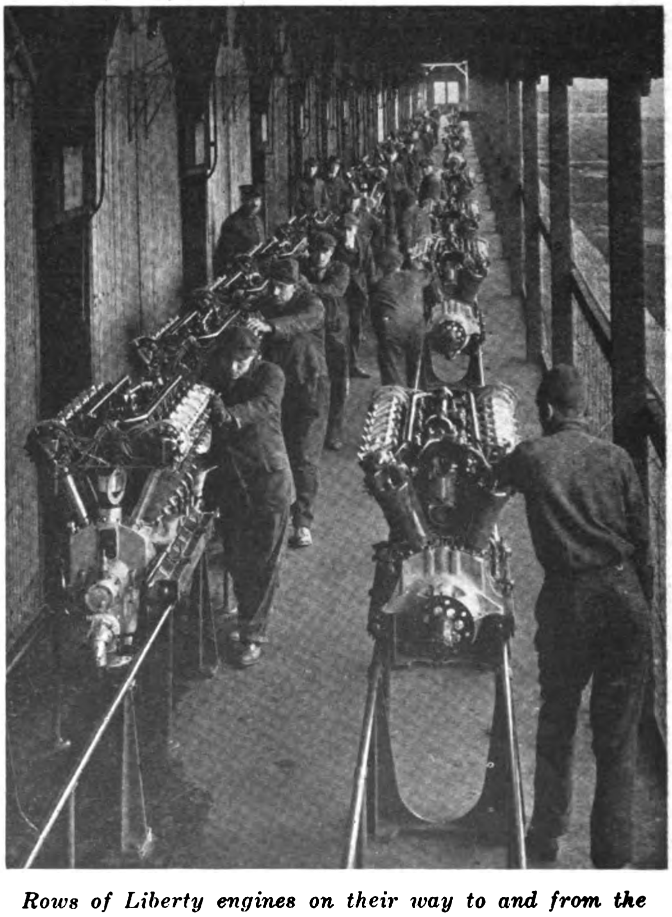
The Grant Motor Car Co. turned out 612 anti-aircraft gun trailers, 830 3-in. field gun trailers, 576 4-ton shop trailers and more than 200,000 155-mm. Mark V shells.

The electric car companies were not behind in this work, as is evidenced by the Anderson Electric Car Co., which turned out ambulance bodies for the G. M. C. chassis.

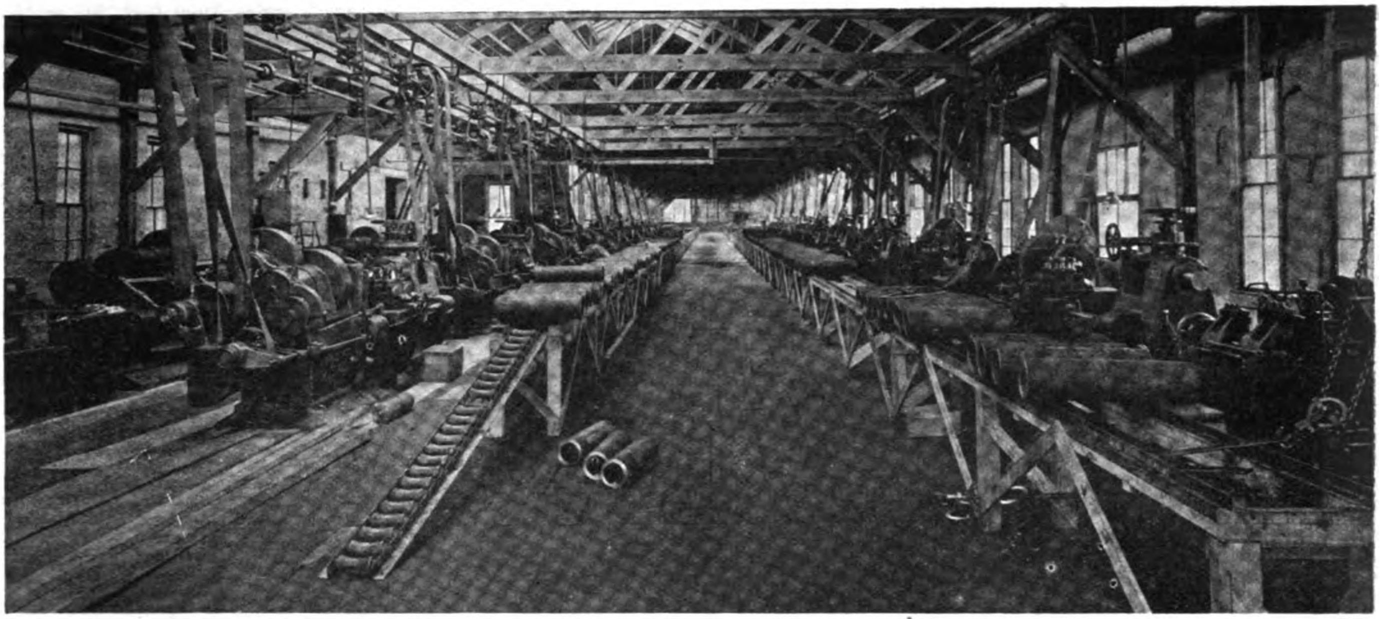
All of the above are random examples of work done by the passenger car manufacturers along lines which were different entirely from their standard products, and they were not alone in this. The truck manufacturers also did work which was a radical departure from anything they had previously been accustomed to.

For instance, the Avery Co. was just about ready to start on self-propelled big gun mounts; the Bates Tractor was making parts for the 4-in. gun mounts; the Columbia Motor Truck & Trailer was making four-wheel trailers for the Quartermaster's Department; the Federal Truck was making artillery tractors; the Kelly - Springfield made 1225 heavy aviation trucks; the United Motors also made heavy aviation trucks. The Class B trucks were made by such concerns as the Gramm-Bernstein, which contracted for 1750, the Lewis-Hall Iron Works, the Service company and J. C. Wilson, the latter concern also having contracted for the Wilson 2-ton and Class AA trucks.

Axle manufacturers also departed radically from their lines in many instances. For example, the Empire concern made airplane propeller hubs and flanges, and airplane drive shafts; the Salisbury Axle Co. made 3-in. anti-aircraft shells and military truck parts, such as drawbars, bumpers, sprag releases, assemblies for Class B trucks, also the front and rear Quad axles.



Rows of Liberty engines on their way to and from the testing sheds



Shells for 115-mm. guns in process of manufacture at the Grant Motor Corp., Findlay, Ohio

The engine manufacturers were generally fortunate to be turning out nothing but engines. However, these engines varied greatly from their standard practice, but now that they have proven themselves in government service will probably be manufactured in a commercial way. Continental, Hinkley, Wisconsin, Hercules and others made the Class B military engine. A variety of truck engines was made by such concerns as Waukesha and Continental, who, in addition to the Class B engine, made four and six-cylinder engines for light ambulances for the medical department, light ordnance trucks, Class AA government trucks, light aviation trucks, heavy aviation trucks, quartermaster trucks, trucks for the Navy, trucks for cantonment camps, fire brigades and the light and heavy Signal Corps work.

Class B clutch and transmissions required the efforts of such concerns as the Covert Gear, Detroit Gear & Machine, Fuller & Sons, Muncie Gear Works, Warner Gear and T. W. Warner. The Grant-Lee company made gears for the F. W. D. trucks, and the American Die & Tool made airplane parts and also got into armored tank production, locomotive building, shipbuilding and kindred lines.

Body Makers Turn to Airplanes

The body manufacturers were in big demand for all sorts of government purposes. The Fisher Body Co. was in a position to turn out 200 airplanes a day when the armistice was signed. It produced large numbers of De Haviland planes and also the training type of planes. The Lang Body made boxes for the Browning machine gun and trays for ammunition. This concern also mounted and crated the reconnaissance and machine gun trucks and did the camouflaging work on these trucks. The Rubay Co. got into airplane work; the Markley Commercial Body Co. produced airplane cylinder boxes and wedges for shipment. Ambulance and transport bodies were made by Erdman-Guider, the Highland Body Co., the Motor Truck Body Co. and the Trippensie Mfg. Co. Escort wagon parts were made by the Sidney Mfg. Co. These are chosen from a wide list, showing the great variety of work that was done in this field and gives some sort of a picture of the disruption necessary in the industry to produce the required material for the government.

Even before this country had declared war, the United States had begun to place contracts with different concerns for war material. For instance, the Peerless company received its first United States contract in June, 1916. During 1917 a great number of contracts for war materials were of course placed, war having been declared in April, 1917, with this country in a tragically unprepared condition. As a result of this, it was not until December that contracts began to be placed rapidly for war material, although we had declared war in April.

During the month of December, Hudson, Reo and a number of others received their ordnance contracts. The airplane contracts received by Packard and Overland were somewhat in advance of this and much nearer the declaration of war. Many of the shell contracts such as Harroun were not placed until March, 1918. Dort received its contract in February, Hupp in May, 1918; Anderson in May, 1918. Saxon and Liberty did not receive their contracts until August, 1918, and the Crow-Elkhart in December, 1918, showing the immense advantage which would have been possessed if this country had utilized the 3 years of war on the other side to get into a real state of preparedness.

A great amount of new plant area was added by the industry during the war, and this is going to be of advantage as soon as the industry gets its stride. At the present time much of it is superfluous. However, the prospects for getting back into bigger production than ever before are so good that any added plant space is not looked upon as a liability, but an asset.

The Willys-Overland Co. added 391,374 sq. ft. for war purposes, the Hudson company added 30,000 sq. ft., Packard added 300,686 sq. ft. for government purposes alone, the manufacture of passenger cars being completely eliminated during the war. The Anderson Electric Car Co. put up a two-story building, 360 ft. by 120 ft. wide. The Federal Motor Truck put up a $250,000 addition; the Gramm-Bernstein more than doubled its plant capacity since the beginning of the war; the Indiana Truck Co. added 53,000 sq. ft.; the Kelly-Springfield built two buildings, one 450 by 62 and the other 592 by 62 ft. The Lewis-Hall company devoted 26,000 sq. ft. of floor space to its Class B contract; the Service company put up a building 775 ft. long by 75 ft. wide; Standard added 18,000 sq. ft., and the United Motors Co. 5400 sq. ft.

Parts and Accessory Makers Also Enlarged Plants

The parts and accessory makers also erected plants and greatly increased their space. For instance, the Continental Motors Co. added 200,000 sq. ft.; the Waukesha increased its plant area 40 per cent; the Warner Gear put up 87,000 sq. ft. in new buildings; T. W. Warner increased its plant by 300 per cent.

The body companies were noticeable in their increase, led by the Fisher Body, which put up an entirely new 10-acre plant to take care of airplane work. Rubay put up 90,000 sq. ft., the Lang Body 24,000 sq. ft., and Erdman-Guider and the Motor Truck Body each 12,000 sq. ft.

The value of the production turned out by the automotive

industries for the government during the war amounts to billions of dollars. It would be hopeless to attempt to list the articles manufactured here or to give any idea of the quantities and the value in money. Taking the Peerless company alone, $37,000,000 worth of trucks were furnished by this one company. As another random example, the Dort had orders for approximately $6,000,000 worth of work, about one-half of which was completed. To give an idea of the quantity of materials that this means, it may be interesting to take other typical examples. Packard delivered over 6,000 trucks, more than 550 Liberty engines, and they were just getting into quantity production on La Pere planes. The Haynes company had completed 4,000 engines and 600 transmissions. Reo turned out 1560 army tractors.

Parts Makers Also Busy

Among the truck manufacturers, when the armistice was signed, Federal had made 1465 trucks and 200 tractors and manufacture was still going on. The value of these trucks was $5,650,000, with $2,000,000 additional in parts. The Gramm-Bernstein had turned out 1750 Class B trucks, the Indiana Truck Corp. 1045 trucks and about 1,000,000 pieces of small machine parts.

The parts makers were not far behind the manufacturers of complete vehicles in the money value or quantity of production turned out during the war. The Standard Parts Co., Cleveland, had completed approximately $10,000,000 worth of manufactured articles for the government; the Covert Transmission about $3,000,000; Rubay, $5,500,000. Continental had turned out 60,000 engines; Hinkley, 3600 up to Nov. 27, 1918; Wisconsin, 15,000; Waukesha, 4500. The Detroit Gear & Machine Co. had made 8000 clutches up to the end of December; Grant-Lees, 2000 sets of gears for four-wheel drive trucks; Warner Gear Co., 6500 transmissions, 700 clutches, 10,000 control sets, 4500 differentials and 5000 steering gears. T. W. Warner was running at 500 transmissions a day when the armistice was signed.

Contributed of Their Personnel

Outside of contributing all of this manufactured production, of which it must be realized the examples given are only scattered instances taken at random from our long list of manufacturers, the automotive companies were also heavy contributors of personnel, not only to the uniformed service, but to the civilian departments of the government. From the Willys-Overland Co. alone 5500 skilled and unskilled laborers entered the service. This is approximately 33 1/3 per cent. This same percentage was reached by other concerns; for instance, the Liberty Motor Car Co., of which 34 per cent of all people employed, including the office and factory force, entered the service. At the Grant factory 584 were enlisted or drafted, or about 65 per cent of the laboring force. To take other typical examples of the number of skilled and unskilled entering the service, Dort lost 180, or 15 per cent; Hupp, 287, or 25 per cent; Anderson, 100, or 16 per cent; Reo, 812, or 20.3 per cent.

The percentage also ran high among the truck manufacturers. At the Avery company, for example, 459 men or 16 per cent of the organization went into service; at the Federal Truck, sixty-five or about 10 per cent; Kelly-Springfield, 160 or 21.3 per cent; Indiana Truck, 110 or 25 per cent; Gramm-Bernstein, 146 or 20 per cent of entire force.

One Company Lost 51 Per Cent of Its Men

As noted, the percentages of men entering the service from the different plants varied very considerably, running all the way from more than 50 per cent down to 5 or 6 per cent. This depended very largely on whether or not the concerns claimed exemption for their men. The parts makers had about the same experience, percentages varying considerably.

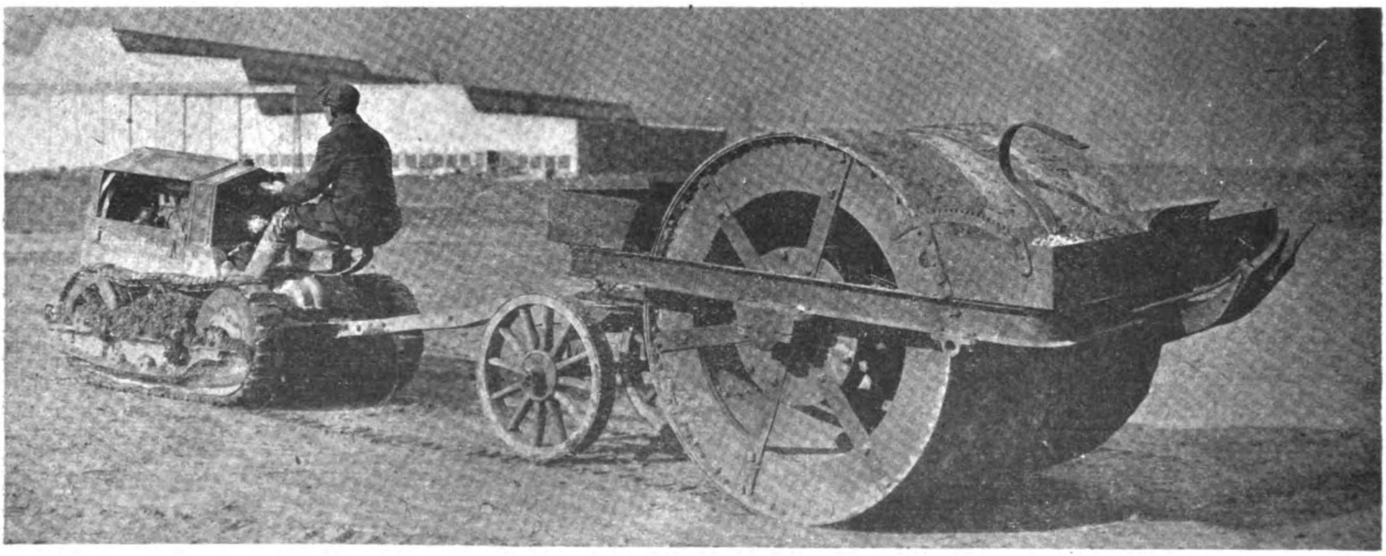
For instance, the Waukesha Motor Co. lost 51 per cent. of its force through enlistment or draft, while the Muncie Gear Works lost five men or about 3 per cent. The average is somewhere around 20 to 25 per cent. Continental, employing a large force of men, lost 1300 men through enlistment, this being about 21.6 per cent of the total employed and forming a fair average from which to base statistics.

The automotive industry contributed heavily from its executive officers to all branches of the service. Taking the office force, the percentages of those entering the service did not run so high, the average being somewhere around 12 per cent. The Willys-Overland Co. had about 175 of its office force in the service or about 18 per cent; Reo had about thirty or about 9 per cent; Haynes had eight or about 13 per cent.

Those entering the service from the offices of the commercial vehicle manufacturers ran somewhat higher in percentage, the average being about 20 per cent. The Lewis-Hall office force lost about 50 per cent through entering the service; Kelly-Springfield, fifteen or 25 per cent; United Motors, seven or 25 per cent; Gramm-Bernstein lost twenty-two from its office force or about 20 per cent of the total. These percentages are lower than the skilled and unskilled laborers, largely due to the exemption pleas entered by concerns for their executives, and also due to the predominating number of older men in the executive and office positions.

Parts Makers Released 20 Per Cent of Force

The parts makers averaged about the same as the truck manufacturers, 20 per cent being the approximate average. Probably as large a percentage as any in the parts making business is exemplified by the Empire Axle Co., which lost nine of its office force or about 75 per cent. The Sheldon Axle lost ten or about 10 per cent; Standard Parts, thirty-five or about 10 per cent; Warner Gear, fifteen or 10 per



Cleveland tractor pulling a road roller in preparing the flying field at the Glenn Martin plant at Cleveland

cent; the Grant-Lees lost 25 per cent; Muncie Gear, 25 per cent, so that, all in all, the average losses in the office staffs of the different companies was about 25 per cent.

The industry is gratified by the fact that many of its prominent members were selected for high civil and military positions. It is impossible to attempt to list the executives of automobile, truck and parts concerns who were commissioned and held high rank in the service. Practically every executive staff of the larger concerns in the business contributed its quota of majors, captains and lieutenants. These men entered the service and in many cases sacrificed large incomes in order to be of assistance to the government. Henry B. Joy, ex-president and director of the Packard Motor Car Co., was a colonel in the Signal Corps; J. G. Vincent, vice-president of engineering of the same company, was a lieutenant-colonel. H. L. Shepler, vice-president in charge of production at the Willys-Overland Co., was a major in the aircraft service. Howard E. Coffin, vice-president of the Hudson company, was chairman of the aircraft board and did much to frame the policy which was eventually developed in our aircraft service. Vice-President Alden of the Timken-Detroit Axle Co. became a colonel in the Ordnance Department and was in charge of the development of tanks. W. G. Wall of the National company became a lieutenant-colonel in the Ordnance Department and distinguished himself in the development of military tractors. This list could be made indefinitely long, telling of the contributions of the executive staffs of the different automobile factories of their men to important uniform and non-uniform branches of the service.

Executives on Patriotic Work

The important work done by executives of the automobile, truck and parts makers in helping the Liberty Loan and War Savings Stamp work cannot be overlooked. Many executives turned over a large percentage of their time to this work. As a typical example, J. D. Dort, president of the Dort Motor Car Co., may be mentioned. When war with Germany was declared, Mr. Dort turned his interests over to others and devoted his entire time to war work, becoming chairman of the Genesee County, Michigan, War Board, which exceeded its quota by $1,000,000 in voluntary subscriptions alone on the Fourth Liberty Loan.

There are many interesting sidelights in connection with what the different companies of the industry did and many fascinating human-interest stories. One of these is the rise of Edwin Denby, treasurer of the Denby Motor Truck Co., through the sheer force of personality. Mr. Denby entered the marines as a private and rose to a captain by the time the armistice was signed.

Spent $12,000,000 for New Buildings

The story of the Willys-Overland Co., which spent $12,000,000 for new buildings, equipment and for changing over old equipment in 19 months and 6 days in order to get into production, is noteworthy. John Willys went ahead and produced airplanes before he ever received an order for them, so sure was he that the government would need this product. Special machinery had to be made by the Overland company in order to produce the French 77-mm. gun carriage. There were over 1600 parts in this gun carriage, of which 146 are forgings, but by the time the armistice was signed the Overland company was putting these through at the rate of twenty-five a day. The manufacture and machining of 8-in. shells was another tremendous undertaking. As an example, every single shell manufactured had to be tested under a hydrostatic pressure of 8500 lb. per sq. in., and the shell had to withstand this or be rejected.

The utility of the type of internal combustion engine developed by the automotive industry proved itself in numerous ways. We are no longer surprised to hear of Cadillac eight-cylinder engines, which we at one time pictured as exclusively a passenger car proposition, actuating 2½-ton artillery or driving the winches for pulling down captive balloons. These and many other adaptations of well-known power plants were common in war service.

The White convoys were distinguished by being merited the Croix de Guerre, this being the first and only instance in French military history of a truck formation receiving this high honor. And yet all of the above is of necessity only a smattering of what was actually done; this country was only in the midst of diverting its entire automotive facilities to war work. Many factories were just converting themselves to their new lines when the armistice was signed and the contracts cancelled, allowing them to hurry back to their normal lines, and many are in the midst of the work of getting back to usual production at the present time.

Experimental Design and Testing of Airplane Ribs

(*Continued from page* 460)

been made on the Type "I" rib, as made in production. These tests were made with the load grading, as shown in Fig. 6, and the load grading as specified by the Army in sand loading of wings. These tests are not only for the standard rib, but for the rib in the section of the wing with the aileron cut out.

It will be noted that the weight of the various ribs started in at 15 oz. and ran as high as 20¼ oz. The average weights of ribs in production is 11½ oz.

The cost of manufacture of this rib as produced is much less than the standard type using veneer for the webs and cutting out various shaped portals.

All tests were made with certified glue, but later some ribs were built up with cold glue and apparently there was no difference in the results. But in production only certified hot glue is used.

The deflection in the table is given for each load of factor of safety of one, and is a convenient indication of rigidity. It is seen that the final type of rib held its original shape the best and that the aerodynamic characteristics will not be appreciably changed in normal flight. In the table on page 458 the deflection is shown for the center section. Space hardly permits of any more detail information on this.

Fig. 7 shows the contour of the rib and the dotted outline shows rib No. 31 with a load 8 times normal load. The total deflection is 23/64 in., or .043 in. deflection for normal load.

The Carburetion Temperature of Oil Mixtures

By C. A. Norman
Professor Ohio State University

THE present article gives a method of determining the temperature necessary to keep in a permanent state of vaporization any oil fraction contained in a carburized mixture. It gives curves applicable especially to the fractions of kerosene and derives the temperature necessary to form a permanent vapor mixture of kerosene and air. The knowledge of this temperature is of very great practical importance. If carburetion at a lower temperature is attempted, then partial condensation will most likely result; hence very incomplete combustion, high fuel consumption, dilution of the lubricating oil in the crankcase, carbon formation on the spark plugs and cylinder walls, unequal firing, etc.—all troubles too well known in kerosene engine practice. If the temperature is much exceeded then avoidable knocking may appear; likewise dissociation of the fuel with carbon even in the inlet passages; finally reduction of power. The point of perfect carburization ought then to be known.

Kerosene is a mixture of fractions with widely varying boiling points. A leading company has communicated to the author the following as a typical composition of kerosene:

	Deg. Fahr.
Boiling starts at	292
10 per cent off at	369
20 per cent off at	386
30 per cent off at	400
40 per cent off at	415
50 per cent off at	422
60 per cent off at	441
70 per cent off at	458
80 per cent off at	476
90 per cent off at	496
98 per cent off at	554

It is seen that nearly 10 per cent of the kerosene under atmospheric pressure boils off above 500 deg. Fahr. and 2 per cent above 550 deg. Fahr. It is tolerably safe to assume that no noticeable fractions boil above 600 deg. Fahr. Now, when these fractions occur in a kerosene air mixture their boiling points correspond, not to the total pressure of the mixture, but to the partial pressure of the fractions in the mixture. Thus, to aid in the distillation of lubricating oil, quantities of steam are blown into the still. Say that the pressure in the still is 15 lb., and that we blow in enough steam to maintain a pressure of 8 lb. of steam alone. Then the pressure of the oil distillate is only 7 lb., and its boiling point lowered to correspond to 7 lb. pressure instead of 15 lb.

The ratio of the partial pressures P_1 and P_2 of the gases occurring in a mixture in weights G_1 and G_2 is

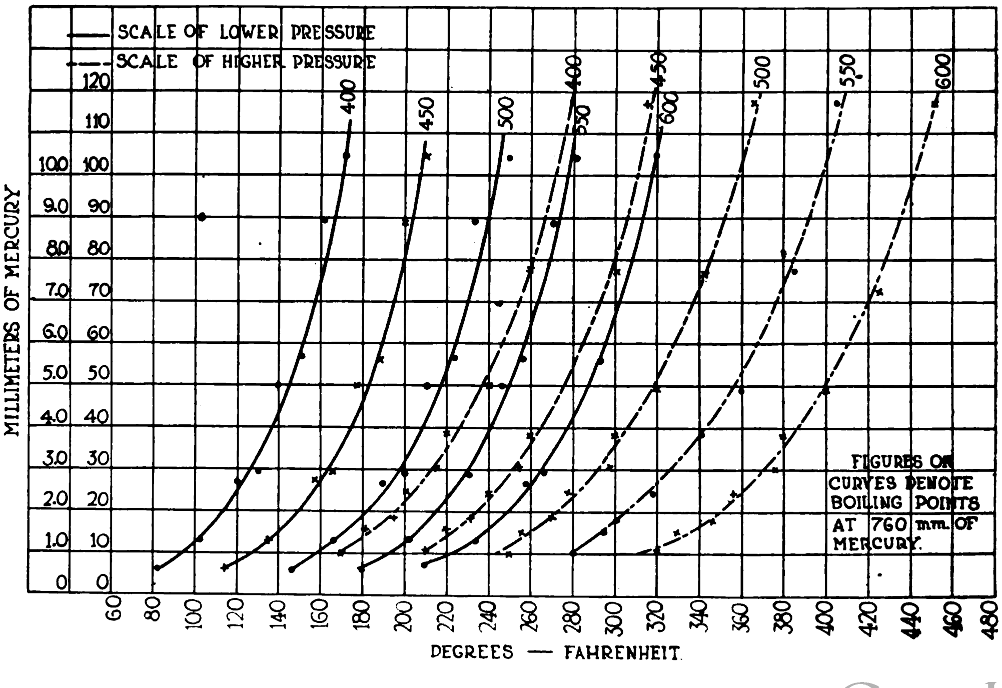
$$\frac{P_1}{P_2} = \frac{G_1 R_1}{G_2 R_2}$$

Here R_1 and R_2 are the "gas constants" of the mixtures.

The gas constant for any gas or vapor is very nearly equal to 1540 divided by the molecular weight of the gas. Thus for oxygen, O_2, the molecular weight is $2 \times 16 = 32$, and the gas constant, $1540 \div 32 = 48$; for nitrogen N_2 the molecular weight is $2 \times 14 = 28$ and the gas constant $1540 \div 28 = 55$; while for air a mixture of N and O with average molecular weight = 29.95. The gas constant is $1540 \div 28.95 = 53.2$.

In order to estimate the partial pressure of kerosene fractions in kerosene-air mixtures we have to find their gas constants with the aid of the molecular weights. These molecular weights can be figured directly from the chemical formula for the fraction. These formulas vary from kerosene to kerosene; but for most practical purposes we may assume the kerosene fractions to be either simple paraffins or naphthenes; in this country the former. The boiling points, molecular weights and gas constants are given in the table on page 491.

It is found that for highest power development it is often necessary to have a somewhat over-rich mixture. For complete combustion 1 lb. of kerosene requires about



Curves showing vapor tensions of paraffins derived by means of Ramsay's and Young's law from those of Octan and Dekan

15 lb. of air. Suppose we wish to be sure of the perfect evaporation of a mixture containing 1 lb. of kerosene to 13 lb. of air.

In the kerosene-air mixture listed in the table, only 2 per cent will at atmospheric pressure boil above 554 deg. Fahr. Let us, for the sake of safety, however, assume a kerosene with 10 per cent boiling at 600 deg. Fahr. In the mixture we would have 0.1 lb. of this fraction, 0.9 lb. of other kerosene and 13 lb. of air. The gas constant of air is 53.2; of kerosene we can assume it to be on an average 8.5.

For the whole mixture it is with sufficient accuracy

$$\frac{13 \times 53.2 + 1 \times 8.5}{14} = 50$$

For the heaviest fraction we shall, for the sake of safety, assume the gas constant rather high than low, say 6.5.

The pressure of the mixture will not exceed 14.7 lb. The partial pressure of the fraction is very low. Such low pressures are more conveniently expressed in millimeters of mercury, the unit usually employed in chemical works; 14.7 lb. correspond to 760 mm. of mercury.

We find the pressure of the heaviest fraction certainly not greater than

$$P = \frac{0.1 \times 6.5 + 760}{14 \times 50} = 0.7 \text{ mm.}$$

The drawing contains a set of curves showing the vapor pressure of various kerosene fractions for varying temperatures. Read from the vertical scale to the horizontal scale, it represents the boiling points, or perfect vaporization temperatures, of various fractions under various pressures. The full-line curves refer to the scale of lower pressures; the dotted curves, to the scale for higher pressures. We find that a fraction boiling at 600 deg. Fahr. at 760 mm. of mercury boils at about 210 deg. at 0.7 mm.

In other words, if the mixture has a temperature of 210 deg. or higher, the heaviest fraction will most decidedly be above its boiling point and no condensation will ensue. In a leaner mixture than the one here assumed the partial pressure of the fuel will be lower, the necessary vaporization temperature also lower. Since the lighter fractions occur in greater quantities, it might be advisable to check up what the average vaporization point for the kerosene will be.

We find

$$P = \frac{1 \times 8.5 \times 760}{14 + 50} = 9.2 \text{ mm.}$$

Taking the average boiling point to be 450 deg. at 760 mm., we find that this corresponds to a vaporization temperature of about 205 deg. Fahr. at 9.2 mm.

There is then no reason to doubt that almost any kerosene will give a permanently vaporized mixture at temperatures betwen 200 and 220 deg. Fahr.

It is very interesting to note that an unusually able experimenter in the field of kerosene carbureters, in private conversation with the writer, gave 220 deg. as the temperature in the intake manifold, at which his device worked most satisfactorily—giving abundant power without knock. Strange to say, at a temperature of around 180 deg. he found much less power with considerable knock.

It should be noted that the temperature of vaporization is not the temperature of the air before mixing. The evaporation of the kerosene consumes heat. The amount of this heat at reduced pressure is not accurately known, but will probably be around 250 B.t.u. per pound of kerosene, or about 20 B.t.u. per pound of air in a rich mixture. This corresponds to a cooling of the air amounting to about 80 deg. Fahr.

Name.	Formula.	Boil. Pt. deg. Fahr.	Molar Wt.	Gas Cnst.
Pentan	$C_{5}H_{12}$	100	72	21.4
Hexan	$C_{6}H_{14}$	160	86	17.9
Heptan	$C_{7}H_{16}$	208	100	15.4
Octan	$C_{8}H_{18}$	257	114	13.5
Nonan	$C_{9}H_{20}$	302	128	12.0
Dekan	$C_{10}H_{22}$	344	142	10.85
Undekan	$C_{11}H_{24}$	384	156	9.85
Dodekan	$C_{12}H_{6}$	418	170	9.05
Tridekan	$C_{13}H_{28}$	454	184	8.35
Tetvadekan	$C_{14}H_{30}$	485	198	7.75
Pentadekan	$C_{15}H_{32}$	519	212	7.25
Hexadekan	$C_{16}H_{34}$	549	226	6.80
Heptadekan	$C_{17}H_{36}$	578	240	6.40
Octadekan	$C_{18}H_{38}$	605	254	6.05
Nonadekan	$C_{19}H_{40}$	626	268	5.73

For perfect vaporization the air before mixing should then have a temperature around 300 deg. Fahr.

For a present-day gasoline with 10 per cent boiling above 400 deg. Fahr. at 760 mm. the computations carried out in the foregoing lead to a vaporization temperature of around 100 deg. Fahr. and an air temperature of, say, 160 deg. Fahr. A cold engine and a cold hood should therefore certainly not be expected to constitute ideal conditions for this fuel.

The curves have been derived from experimental curves for Octan and Dekan by means of Ramsay's and Young's law. This law states that for the same pressure the absolute boiling temperatures of two related chemical substances stand to each other in a fixed ratio. Thus, if Dekan at 760 mm. boils at 312 deg. Fahr. = 772 deg. Fahr. abs., and at 25 mm. boils at 140 deg. Fahr. = 600 deg. Fahr. abs., then a fraction boiling at 500 deg., at atmospheric pressure, will at 25 mm. boil at

$$\frac{(500 + 460)}{772} \times 600 = 746$$

deg. Fahr. abs. = 746 = 460 = 286 deg. Fahr.

With the aid of this law we can exterpolate the curves to any desired extent.

Suppose, for instance, we have a gasoline mixture which vaporizes completely at zero Fahrenheit = 460 deg. Fahr. abs. The partial pressure of the gasoline in the mixture may be 10 mm. What would be the average boiling point of this mixture at atmospheric pressure? We notice that the 400 deg. fraction under 10 mm. pressure boils at 170 deg. Fahr. = 630 deg. Fahr. abs. Consequently the gasoline at issue would at atmospheric pressure show an average boiling point of

$$\frac{460}{630}(400 + 460) - 460 = 165 \text{ deg. Fahr.}$$

In other words, an aviation gasoline vaporizing completely at zero degrees Fahrenheit boils considerably below the boiling point of water; yet does not, on the whole, need to be such an extremely volatile product.

The writer was led to the foregoing investigation through a conversation with Mr. F. W. Howe, chief engineer on motor trucks to the International Harvester Corp. To Mr. Howe the potential value of the data furnished had long been apparent.

It is to be noted that all above temperatures referred to carburetion by perfect vaporization. Carburetion by mechanical suspension resulting in a so-called fog mixture may be possible at lower temperatures.

HORSELESS AGE SUBSCRIBERS
Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation, Address 243 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries-The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Executives Who Understand Labor Needed

IT is a little surprising that we have not insisted upon the understanding of human principles and impulses in our industrial executives to a greater degree. We are prone to put men into executive positions, primarily, because they understand the products and the processes of manufacture when the principal problem which confronts them is the human problem.

This tendency to minimize the study of human affairs has resulted in the neglect of this study by most industrial executives to such a degree that each development of industrial disturbances finds us almost as far away from any idea of solution as before.

Fortunately, there is a distinct improvement in this direction. We no longer speak of labor as some abstract problem, not related to living and not concerned with social and political environment. We have thrown away the idea that labor interests us merely for so much time and so much physical accomplishment.

The rest must come. To successfully manage an industrial establishment in the future will demand a consideration of human affairs, deep enough to give a reasonable understanding and sympathetic enough to breed intelligent tolerance.

The struggles for self-expression and a measure of control in the management of his own destinies have impelled the man to turn his attention from political to industrial development and the recognition of this by the industrial executive must bring the study of causes and effects which is required for solution.

Wasted Money

HUNDREDS of thousands of shell blanks are lying in the yards of automobile and other factories that were working on shell contracts when the armistice was signed. The Government ordered in many instances that the work on these shells be stopped on Jan. 31. The purpose is to take the blanks to the Government arsenals and finish up the work later, perhaps under a different administration.

The question that naturally springs up immediately is: Why not finish up the shells in the plants where the blanks are stored? The forging companies finished their work and turned the blanks over to the plants where they were to have been machined. These plants were busy on machining work and in numberless cases had hundreds of workmen employed on the job when they had to lay off when the Government stepped in and stopped the work.

It is going to cost the Government additional money to move the blanks to the arsenals and there to set up the machinery and heat-treating apparatus to take care of the work. The plants could have efficiently finished the work on the spot and painted the shells and turned them over for storage. The men who were employed on this work could have been kept employed and not turned loose and it would have given the factories an opportunity to have gradually absorbed this labor into their normal lines.

The machinery was all set to do the work and to clear away these orders in fast time. Why stop them in the middle of the work? The machinery had to be taken down and stored and there it lies in these plants waiting for Government adjustment, while the blanks lie out in the factory yards, awaiting the time when the Government will move them away to the arsenal. This requires twice the transportation work, twice the manual handling of the forging and many times the work in setting up machinery instead of using what was already set up and running on regular production. It is indeed difficult to understand why the run was not carried through to the exhaustion of the blanks as long as the shells are going to be made anyway.

Keep Fuel in Mind

NOW that the excitement of the show season is passing like a wave over the country, and attention is swinging rapidly back to peace time channels, do not let us forget some of the big things that were brought to our attention during the past few weeks.

The fuel situation is a prominent case in point. It has always been difficult for the experimental department of a factory to get money appropriations when the production and sales departments were clamoring for funds, but it would be well for every factory in the business to set aside a sum of money for the research men to use in their studies of the fuel situation.

Do not let the movement for a fuel section of the Society of Automotive Engineers fail to go through to its logical conclusion. This is a matter which requires constant thought and study in order that the development on the engineering side of the business shall keep pace with what is sure to occur in the refining industry. We know from what unbiased experts told us at the S. A. E. meeting in New York that a continuance of the present fuel uses in the present manner and with the increased requirements due to trucks and tractors that the price is sure to advance materially.

The industry will be hampered by increases in the price of fuel, therefore the industry should do its part in forestalling these either by aiding in the development of engines or devices that will utilize other and more plentiful fuels. The money to carry on the necessary research work can readily be contributed by the industry either through its own companies, through the S. A. E. or both. There is no more vital problem confronting us to-day, and we would be failing in ordinary common sense if we did not continually study the fuel prospects of 1921 and 1922. If a reminder is needed, remember that the *curve of crude consumption has crossed the curve of crude production.*

Disposition of Railroads Important to Industry

THE statements made in and out of Congress in regard to the disposition of the railroads and the plans which have been brought up by the late Directer General and others who have given the railroad situation some study from the point of view of the necessities of the railroads or the political effect of certain methods of handling them, calls to our attention the fact that very little has been said about the effect of the disposition of the railroad problem upon the country's industries and economic development.

Perhaps this is to some extent the fault of the business men in this country who paid no attention to the railroad question in the past except to appear in Washington at regular intervals to fight against an increase in rate. Little discussion has occurred on this subject in the Chamber of Commerce and in the meetings of other business bodies which would indicate that the business men of this country fail to realize the intimate relation between the railroad problem and the possibilities of their own business.

Manufacturers in the automotive field drawing raw materials from many sources, depending upon transportation by railroads to a very large degree for the continuance of their supplies and for the operations of this tremendous industry, should be thoroughly concerned with the proposed methods of dealing with the railroad situation and should make it their business through their associations to see that their influence is exerted in favor of such a method of solving the future operation of the railroads as will assure the proper extension of railroad facilities in this country, the adequate increase of terminal and distributing facilities to keep pace with the growing traffic on the railroads and the adequate up-keep of the trucks and equipment so that the service upon the present lines will be maintained at its maximum.

The failure of the business men of this country to exert their influence for the proper extension of transportation facilities of all kinds in the past should only emphasize the lesson which has been pointed out by the war necessities, that is, that the growth of industry depends upon adequate extension and up-keep of transportation facilities to such a degree that no group of manufacturers can afford to have the matter decided at a peace conference or by political adjustment or without respect to the industrial necessities of the case.

The time is ripe for organized bodies to concentrate on the problem and possibly for the appointment of committees representing industry to investigate the matter and present the industrial view of the railroad question to Washington.

Will Road Racing Be Revived?

WILL racing be revived? There can be no question but that racing, properly and scientifically restricted racing, over highways for long distance provides the motor car engineer and builder with a means of testing for which there is no adequate substitute. It can be made, by suitable regulations, the supreme test of efficiency rather than a mere contest of speed. It is expensive and, therefore, requires commercial competition to influence the manufacturer to take it up. Perhaps that competition will be supplied by foreign makers who may find it desirable to revive racing in order to build up prestige for their products; we cannot say, but it seems to be at least a possibility.

Latest News of the

New Models and Strong Representation of Parts Makers at K. C. Tractor Show

Automobile Practice Adapted to Tractor Design—New Models Emphasize Tendency—Thorough Enclosure of Working Parts Popular—Parts Makers Show Realization of Tractor Importance by Complete Exhibits

KANSAS CITY, Feb. 26 (Special Telegram).—Clean-cut lines and thorough enclosure of working parts are strongly emphasized at the Fourth National Tractor show, which is running here this week. Most of the new models emphasize tendency and some of them are worthy additions to the few makes that have already worked toward this end.

A case in question is the new Twin City three-plow tractor which is undoubtedly one of the best jobs yet produced. It is a well balanced design, clean-cut in appearance and exceptionally accessible. The use of a 16-valve engine is an example of how automobile practice can be adapted to tractor design. The new four-wheel-drive Heinz is the simplest type of this drive yet produced, and its development will be watched with interest.

A large part of the show is devoted to implements designed exclusively for tractor use, and these are improved designs and stronger than those heretofore marketed for tractors. It is now recognized that more strength must be put into a tractor plow than a horse plow if satisfactory service is to be given. Other types of specially designed tractor implements are on hand in greater numbers than ever before, including disk harrows, corn planters, silo fillers, cultivators and threshing machines.

Enclosed Drive Through Axle

The show is not only the greatest tractor show ever held, but containing, as it does, exhibits of all the important tractor and tractor implement makers, as well as a most imposing array of makers of such parts as engines, transmission systems, ignition apparatus, carbureters, radiators, castings, forgings, stampings, etc., it ranks as one of the greatest shows of automotive apparatus ever had.

The general character of the show is high grade in every respect. It is staged in a one-story frame $40,000 building, erected in the last three weeks for the purpose and which will be torn down as soon as the show is over. In the mechanical line there is a good deal that is new, though most of the novelties are quite divergent in character, so that it is difficult to discover distinct new tendencies.

One exception must be made to this general statement, namely, that there is a recognizable tendency toward enclosed drive through the axle. This practice, almost unknown four years ago, is to-day found on a dozen tractor models and is constantly gaining ground.

Front Axles Clumsy

From an inspection of models exhibited it is evident there are two schools of design, which may be referred to as the strap iron school and the drop forging and casting school.

The first builds all the structural parts of rectangular bar steel and angle iron while the latter uses drop forgings or castings. The difference begins at the front axle, where one school uses a built-up construction and the other a drop forged one-piece axle. We had occasion last year to remark on the great number of clumsily designed front axles which were excusably only in experimental jobs. There has been little change since. In explanation it should be stated that during the war it was impossible to get dies made for forgings and since the armistice there has not been sufficient time to allow makers to redesign. On the whole, It may be said with assurance that front axles are a part in which there is much room for improvement.

There is one factor which is retarding progress along sound engineering lines, and that is that many farmers do not appreciate good engineering. A farmer examining one of the best tractors exhibited, remarked that there was too much fine machinery in the tractor. He recognized the quality of construction, but it actually repelled him. Some day he will probably learn that fine machinery is not synonymous with delicate machinery and that a machine carefully designed with respect to stress imposed on its parts is sure to give greater satisfaction than one bearing marks of crudeness all over.

Increased Use of Springs

Springs are used to an increased extent, especially in front. Some employ semi-elliptics while others use coils on the steering knuckle pins. While the spring action may be made the same in both, it is evidently accompanied by more sliding motions where coils are used and where the machine has frequently to work in a cloud of dust the sliding motion should be reduced to minimum. Spring suspension at the front end can be readily obtained and as it eliminates some of the short period vibrations which make it so difficult to hold parts together in a tractor it will become a universal feature in time.

Little Change in Frames

There is little change in frames, but more designers are dispensing with a separate frame. In this way weight is saved and in some cases increases the accessibility of important parts.

Several new engines are exhibited, including the Walker overhead camshaft type, and entirely new type in the tractor field. It tends toward clean-cut design as all moving parts are enclosed. There is a considerable number of excellent tractor engines on the market and any concern about to enter the field as an assembler will have no difficulty in securing an engine suitable to requirements.

No departures in practice are noticed in carburetion and ignition, but the size of temperature regulators and indicators is making headway. This is not surprising when it is remembered that the successful burning of kerosene depends so much on proper engine temperatures.

Lengthwise Worm Drive Gaining

In transmissions and final drives there is a wide variety of layouts. Some accomplish the necessary gear reduction which for conventional engine speeds and drive-wheel diameters range between 40 and 50, in a single step, while others use as many as five distinct steps for gear reduction. It is not necessary to state that, other things being equal, the fewer the reduction steps the better, as each transmission of power from one shaft to another is accompanied by loss. The all-spur type of drive continues with several adherents, though most newer designs have the engine lengthwise. Worm-drive is gaining. There is a notable tendency to use the worm in first gear reduction and spur gears or chain drive for final reduction. This overcomes the difficulty of enormous tooth pressures and thrust loads encountered where the worm is used for final drive.

There are a few striking departures from established practice. The Heinz is one, which is a four-wheel-drive type in which the complication ordinarily asso-

Automotive Industries

Citroen Post-War Car Out

Has First French Post-War Car—$1,450 to $1,960—Plans 100 Daily

PARIS, Feb. 12—André Citroen will produce the first really post-war automobiles in France. It will be on the market in about one month. His production will be 100 per day from the middle of April. Although a few other French manufacturers have cars almost ready for delivery, nobody else has got down to a production basis, nor has any other firm announced prices.

Citroen is specializing on a single model 10 hp., four-cylinder block engine of 65 x 100 bore and stroke. It has forced feed lubrication, high tension ignition, a three-speed gear box and final drive by Citroen herring-bone gears; left-hand steering is fitted; Michelin steel disk wheels have been adopted; wheel base of this car is either 98 in. or 110 in.; track is 46 in.; weight of the car is 1450 lb., completely equipped; speed on the level is 40 m.p.h., and gas consumption is 31 miles per American gallon. The car is equipped with electric lighting and starting.

As a three-seater, this car will be put on the market at $1,450. Price with four-seater body is $1,590, with inside steering body the price is $1,600 and as a town coupé, $1,960. The same chassis is also built with an express delivery body carrying a load of 550 lb., the price of this being $1,480.

Before the war, Citroen was engaged in the production of gears for automobiles. Before the signing of the armistice he was producing 50,000 shells per day. As the factory has never before built automobiles, the change over from a war to a peace basis is exceedingly rapid. None of the old French automobile firms have been able to get back to automobile production in such a short time. In addition to automobiles, Citroen will produce bicycles and sewing machines.

Columbia Six to Be Exhibited at Lyons Fair

DETROIT, Feb. 24—The Columbia Motors Co. will exhibit one of its model sixes at the fair in Lyons, France. The car was shipped a month ago.

Briscoe Has Space at Lyons

JACKSON, MICH., Feb. 19—The Briscoe Motors Corp. will exhibit one of its cars at the Lyons Fair through Messrs. Dutrieu & Co., Paris.

Provisions in the Revenue Bill

Three per cent tax on motor trucks and trailers.
Five per cent tax on passenger cars.
Five per cent tax on tires, parts, accessories and inner tubes.
Ten per cent tax on shows.
Ten dollars annual tax on taxicabs seating 7 or less.
Twenty dollars annual tax on taxicabs carrying more than 7 persons.
Three per cent of transport cost for freight by truck in competition with rail or water.
Five per cent of transport cost for express by truck or passenger car in competition with rail or water.
Eight per cent of transport fee for carrying passengers by truck, passenger car or motorcycle in competition with rail or water.

Signs New Revenue Bill

Law in Force at Once—Will Tax Trucks, Passenger Cars and Accessories

WASHINGTON, Feb. 24—President Wilson to-day signed the new Revenue Bill.

The law becomes effective beginning Feb. 25. The provisions, which were published in detail in a recent issue of AUTOMOTIVE INDUSTRIES, include a tax of 3 per cent on motor trucks, trailers and the equipment, including tires, tubes and other parts; 5 per cent on passenger cars and all other automobiles, including equipment, excepting on tractors, which are not taxed, and 5 per cent on tires, inner tubes, parts and accessories made for automobiles and sold to any person other than an automobile manufacturer. A tax of 1 cent for each 10 cents is assessed on tickets of admission and supplies to automobile or parts shows held during the year.

The tax of 3 per cent on motor truck haulage where it competes with rail or water transportation of freight remains in the bill, and there is a tax of 1 cent paid for motor truck express where it

(Continued on page 501)

Stage for Makers' Aero Exhibit Set

Eighty-Five Exhibits Scheduled—Cabinet Officers to Be Present

NEW YORK, Feb. 25—Preparations for the Aeronautical Exposition of the Manufacturers' Aircraft Association are completed and arrangements have been made for displays by 85 exhibitors in Madison Square Garden and the 69th Regiment Armory for the two weeks beginning March 1. The semi-official character of the show has brought about the co-operation of the war, naval, post-office and interior departments, and the program as arranged designates Monday, March 3, as Army Day, when Secretary of War Baker will deliver an address. It is expected that Secretary Burleson of the Postoffice Department, Secretary Daniels of the Navy Department and Secretary Lane of the Interior Department will also be present.

The largest airplane on display is the F5L U. S. Navy flying boat, capable of carrying fifty people. The letter F stands for Felixstowe, the British Naval Construction Station. The figure 5 designates the series number and the letter L indicates that the plane is equipped with the Liberty engine. This ship is an adaptation from a British flying boat. During the war it is used as a submarine chaser, has an upper wing span of 103 ft. 9 in. and a lower wing span of 74 ft. 4 in. Its length over all is 49 ft. 4 in. It stands 8 ft. 9 in. from the ground to the top wing. The chord is 8 ft. and the gap 8 ft. 10 in. Although its gross weight is 13,000 lb. it has a maximum speed of 87 m.p.h. and can climb to 2625 ft. in 10 min. It is equipped with two Liberty engines.

That the exposition will have a distinctly international character is assured by the exhibit of the American built adapted Handley-Page, the Caproni triplane, Spad scout, Breguet, a captured German Fokker D-7 and other foreign planes.

The Glenn L. Martin bombing plane, a biplane engined with two Liberty engines, will be displayed. Both wings are of the same span, 71 ft. 5 in. The length overall is 44 ft. 10 in. The height is 14 ft. 7 in. It has an inner surface of 1070 sq. ft. Its gross load is 9663 lb. In speed it outstrips all of its huge rivals, being officially credited with 118 m.p.h. and a climb of 10,000 ft. in twenty-one months. Another type of British machine will be the SE5, which at one

time during the war created consternation among the Germans.

Another feature of the Italian section will be the SVA Gabriel D'Annunzio, the Italian poet, used in his propaganda trips in Vienna.

There will also be a Nieuport Breguet and a LaPere. The latter plane was built in this country by the Packard company at Detroit.

The balloon exhibit will take up a large portion of the air space in Madison Square Garden.

—

List of Exhibitors at Aeronautical Exposition March 1 to 15, 1919

Empire Art Metal Co., College Point, L. I.
Arthur Johnson Mfg. Co., New York.
Dodge Mfg. Co., Mishawaka, Ind.
Valentine & Company, New York.
Zenith Carbureter Co., Detroit.
Wellington, Sears & Co., New York.
John A. Roebling's Sons Co., Trenton, N. J.
Eastman Kodak Co., Rochester, N. Y.
Motor Compressor Co., Newark, N. J.
Cold Light Mfg. Co., New York.
Livingston Radiator Corp., New York.
American Balsa Co., New York.
Jones Motrola Company, New York.
Champion Ignition Co., Flint, Mich.
Dayton Eng. Lab. Co., Dayton.
Ajax Auto & Sheet Metal Co., New York.
Stone Propeller Co., Dayton, Ohio.
Aerial Age, New York.
Splitdorf Electrical Co., New York.
National Cash Register Co., Dayton.
Jamestown Propeller Co., Jamestown, N. Y.
American Propeller & Mfg. Co., Balt., Md.
Hartzell Walnut Propeller Co., Piqua, Ohio.
Dayton Wire Wheel Co., Dayton.
Lunkenheimer Co., Cincinnati.
General Ordnance Company, Groton, Conn.
Society of Automobile Engineers, New York.
Gardner Moffat Company, Inc., New York.
Torrington Company, Torrington, Conn.
Simms Magneto Co., East Orange, N. J.
Triplex Safety Glass Corp., Mount Vernon, N. Y.
Radium Dial Co., Pittsburgh.
American Bosch Magneto Co., New York.
Detroit Accessories Corp., Detroit.
Sterling Engine Co., Buffalo.
Perry Austen Mfg. Co., Grasmere, S. I.
Dayton-Wright Airplane Co., Dayton.
Curtiss Aeroplane & Motor Corp., Buffalo.
L. W. F. Engineering Corp., College Point, L. I.
Wright-Martin Aircraft Corp., New Brunswick, N. J.
Aeromarine Plane & Motor Co., New York.
Thomas Morse Aircraft Corp., Ithaca, N. Y.
Burgess Company, Marblehead, Mass.
Gallaudet Aircraft Corp., East Greenwich, R. I
B. F. Sturtevant Company, Hyde Park, Boston, Mass.
Packard Motor Car Company, Detroit, Mich.
Lawrence Aero Engine Corp., New York.
Gio Ansaldo & Co., New York.

Cantilever Aero Co., New York.
L. Sperry Aircraft Co., Farmingdale, L. I.
Boeing Aeroplane Co., Seattle.
Glenn Martin Co., Cleveland.
Stewart Hartshorn Co., New York.
Matthews Bros. Mfg. Co., Milwaukee.
Budd Wheel Corp., Philadelphia.
A. G. Spalding & Bros., Nassau St., New York.
Titeflex Metal Hose Corp., Newark, N. J.
Doehler Die Casting Co., Brooklyn.
Norma Co. of America, New York.
Stromberg Motor Devices Co., New York.
United Aircraft Engineering Corp., New York.
Anderson Forge & Machine Co., Detroit.
Wyman-Gordon Co., Worcester, Mass.
Standard Parts Co., Cleveland.
Mossberg Co., Attleboro, Mass.
Aero Science Club, New York.
Dural Rubber Corp., Flemington, N. J.
Aeronautical Society of America, New York
Rich Tool Co., Chicago.
Hess-Bright Mfg. Co., Philadelphia.
Liberty Starter Corp., New York.
Ericsson Mfg. Co., Buffalo, N. Y.
B. F. Goodrich Co., Akron.
Champion Spark Plug, Toledo.
U. S. Light & Heat Co., Niagara Falls.
Standard Turnbuckle Co., New York.
A. J. Meyer Mfg. Co., West Hoboken, N. J.
Junior Plattsburg, Inc., New York.
Class Journal Co., New York.
Edison Electric Appliance Co., Inc., New York

France Will Need 40,000 Tractors

More Than 8,000,000 Acres to Be Cultivated Mechanically—Only 3033 Tractors in France

By W. F. Bradley

PARIS, Feb. 15—France can absorb 40,000 agricultural tractors during the next four or five years, according to an estimate made by Representative Compère-Morel of the Agricultural Commission. This estimate, which appears to be a very moderate one, is based as follows:

In the period immediately preceding the war, France had 44,500,000 acres of land under cultivation for grain, potatoes and beets. It is estimated that one-quarter of this area, or 8,600,000 acres, will be cultivated by mechanical means within a very short time. These 8,600,000 acres will have to be plowed in 100 days, on an average; but two-thirds of this land, which is made use of for autumn sowing, will have to be plowed in a period of about sixty days. This gives, therefore, 5,500,000 acres of land to be worked in sixty days, or 98,000 acres per day. It is estimated that a tractor will plow 2 2/5 acres per day. This is probably a rather liberal estimate. On this basis, therefore, 40,000 tractors are required.

A short time ago, figures were issued showing that France possesses only about 800 agricultural tractors. These figures were incomplete. The total number of tractors in service at the end of December, 1918, was 3,033, composed as follows: One thousand eight hundred and thirty-five belonging to French farmers, 898 belonging to the Government and loaned to farmers on special terms, 300 tractors in Government's reserve. Of the 898 practically all were of American origin, for only forty-seven had been bought from French manufacturers, as follows: Filtz, 20; Doizy, 12; De Dion-Bouton, 3; Tourand-Latil, 10, and Julien, 2.

In the opinion of Representative Compère-Morel, the immediate requirements of France will have to be met by gasoline tractors. But the greatest development, he considers, will be with electrically propelled tractors, the electric current being generated either from water power or from wind mills. At the present time all tractors are either gasoline or steam driven.

—

Big Merger Rumor

DETROIT, Feb. 24—The automotive world awaits with interest the announcement expected any day of a big merger of automobile, truck and tractor companies into an organization patterned after General Motors. Norval A. Hawkins, former sales manager of the Ford Motor Co., is busy upon the project but has made no statement regarding his plans. He is said to be backed by Kuhn-Loeb Co., a New York banking house.

Many Detroit companies have been mentioned as possible units in the proposed corporation. It is said to-day that the following five concerns may form the nucleus of the Hawkins organization. These companies are the Commerce Truck Co., the Signal Truck Co., Grant Motor Car Corp., the Doble-Detroit Steam Motor Co. and the Lincoln Motor Co. The Saxon Motor Car Co. and the Hupp Motor Car Corp. have also been mentioned, but officials of these two concerns emphatically deny the rumor.

—

NEW YORK, Feb. 25—Kuhn-Loeb Co. deny that any plans for financing or organizing a merger of automobile interests under Norval Hawkins is contemplated. The bankers state that they have heard the rumors for several weeks, but disclaim any knowledge of them other than as current gossip.

—

Record Flight from Washington to New York

WASHINGTON, Feb. 24—Lt. Frank H. Harmon, pilot of Bolling Field, Anacostia, made a record flight from Washington to New York in a La Pere plane, landing at Hazelhurst, N. Y., 85 minutes after his take-off at Bolling Field, on Feb. 19. In this flight a straight distance of 269 miles was covered, making the average speed 189.9 m.p.h.

—

Agreement Reached on Informal Contracts Bill

WASHINGTON, Feb. 26—After a long disagreement by the Senate and House conferees over the bill to validate informal war contracts a compromise was reached to-day that gives promise of early action and passage of the law. The deadlock was over the payment of contracts for metals and minerals ordered and production of which had been stimulated by the war contracts. The bulk of the contracts validated by the bill total over $2,000,000,000 and include business with the automotive industry of more than $300,000,000.

—

Air Regulations Under Department of Commerce

WASHINGTON, Feb. 26—President Wilson to-day recommended that aerial licensing and regulation be placed under the Department of Commerce as suggested by the National Advisory Committee for Aeronautics, and asked Congress for the necessary legislation. Secretaries Baker, Daniels and Redfield also indorsed the plan.

The legislation would give the Department of Commerce authority to issue licenses for civilian flyers and includes an appropriation of $250,000. Without some sort of regulation and control of licenses, it was pointed out, there would be many fatalities caused by amateur flyers, and in addition airplanes might be used for smuggling from Mexico or Cuba.

Organizing Federal Highway Committee

All Bodies Interested in Road Contruction to Be Fully Represented

WASHINGTON, Feb. 21—As a result of the meeting of various organizations interested in highway construction in Chicago recently the National Highway Committee is being organized to represent practically every organization for the construction of roads and those interested in this work and to secure intensive industrial support for road construction.

S. M. Williams, president of the Highways Industries Association, has appointed the State Highway Commissioners and Engineers and various prominent men throughout the country to the committee, giving each State representation of three or more and in each case selecting men known for their present interest and activity in highway development. Total membership of the committee will be about 300 and will include the presidents of various prominent national organizations such as the American Road Builders' Association, National Automobile Dealers' Association, etc.

Although the Federal Highway Committee is not yet completed, it is already assuming important proportions. Following is the organization as formed to date:

Federal Highway Committee

W. T. White, Cleveland.
F. A. Seiberling, Akron.
R. D. Chapin, Detroit.
A. G. Batchelder, Washington, D. C.
Coleman du Pont, Wilmington, Del.
F. A. W. Vesper, St. Louis.
A. H. Blanchard, New York.
Chas. H. Davis, Cambridge, Mass.

Half Billion Planned to Build Highways

WASHINGTON, Feb. 24—Expenditures for highway work in the United States this year are likely to amount to a half billion dollars, according to the Bureau of Public Roads. The bureau estimates the expenditures for roads and bridges at \$385,000,000, or \$110,000,000 more than the average expenditures for 1916 and 1917. This does not include additional Federal funds which will be available if the amendment to the Post Office Appropriation bill, making \$50,000,000 immediately available and \$75,000,000 more on July 1, is enacted into law.

Estimated work under control of the state highway departments includes \$45,000,000 for the construction of 5,000 miles of road now under contract, \$30,000,000 for 4,000 miles of construction ready for contract, \$100,000,000 for 16,000 miles of contemplated construction, and \$60,000,000 for maintenance of 200,000 miles. Expenditures of counties, and local districts are estimated at \$100,000,000 for the construction of 150,000 miles and \$50,000,000 for maintenance of 100,000 miles.

Federal Highway Plan Outlined in Bill

Provides for Commission of Five Members and National System of Main Highways

WASHINGTON, Feb. 25—The bill to create a Federal highway commission, to establish a National highway system and promote road construction, introduced by Congressman Townsend, provides for a commission of five members, to be appointed by the President. Provisions are made for a complete system of highways and post roads, and specifies that no less than two main trunk line roads are to be in each State. The commissioners will receive \$10,000 yearly salary. They will have complete control of highways with power to determine types of construction and improvement, repair and maintenance.

The War Department is authorized to deliver to the commission any vehicles needed for use in the construction and control of highways, without charge, and in addition, any road machinery and equipment requisitioned.

Road building along economic, scientific lines, will be given a tremendous impetus the country over by the passage of the bill, in the opinion of Roy D. Chapin, former chairman of the Highways Transport Committee of the Council of National Defense and chairman of the Highways Committee of the National Automobile Chamber of Commerce.

"The United States is on the eve of a revolutionary epoch in highways transportation," said Mr. Chapin. "Hundreds of millions of dollars are available now for construction throughout the country and scarcely a day passes that we do not hear of some new movement looking toward better highways.

"The Townsend bill provides a sure means for such a program and it is safe to say that all who understand the importance of efficient highways transportation will be solidly in favor of its adoption by Congress at the earliest possible moment."

No State will benefit from expenditures of Federal money for highway construction until it approves this bill. The bill was read to the House and referred to the Committee on Post Offices and Post Roads. There is little chance that it will pass during this session. Following is the complete bill:

That there is hereby created a Federal highway commission, and to provide a connected system of main highways adequate to sustain the demands of interstate commerce, to provide adequate post roads for the transportation of the United States mails and parcel post, and to provide for the common defense and promote the general welfare of the people of the United States there is hereby authorized to be established, constructed, and maintained a system of highways, hereinafter referred to as the national highway system, to comprise not less than two main trunk-line roads in each State, and joining the national highway system in the adjacent States and countries. The term "commission" used in this act shall mean the Federal highway commission, hereinafter referred to as commission; a highway, within the meaning of this act, shall be deemed to include the

Elysee-Palace Hotel for Auto Sales

Citroen Buys Hotel for Sales Building—Avenue Champs Elysees Auto Row

PARIS, Feb. 10—The Elysée-Palace Hotel, the biggest and the most luxurious of the hotels of Paris, situated in the Champs Elysées, recognized as the finest avenue in the world, has been purchased by André Citroën, and it is declared that it will be used as an automobile showroom and business headquarters.

This hotel belonged to the Compagnie Internationale des Wagons-Lits, and Citroën has secured it by the purchase of a predominant number of shares in this concern. The public is at a loss to understand how Citroën can make use of such a huge building as automobile showrooms and office. The hotel must have not less than 1000 rooms, including several handsome halls. It is at present occupied by the Quartermaster and Signal Corps of the American Army, but, being much too big for these services, they will move out at an early date.

Citroën is only just entering the automobile field, and the car he is producing is of a popular type, sold at a very moderate price. It is not the class of cars usually associated with the luxurious Champs Elysées showrooms.

The Avenue des Champs Elysées is becoming more and more commercialized by the automobile industry. Originally the trade was located in the Avenue de la Grande-Armée, which is a continuation of the Champs Elysées. It is on the north side of the Etoile Monument. Now manufacturers and dealers are coming to the more luxurious south side of the monument. In addition to Citroën, those who have secured or are preparing to secure showrooms in the Champs Elysées are: Fiat, Rolls-Royce, Panhard & Levassor, Renault, Delaunay-Belleville, Lorraine-Dietrich, Braiser, Sizaire-Berwick, Bellanger and Berliet. The German Mercedes showrooms in this avenue have been used by a war charity organization for the past two years, and probably will be taken by some French automobile firm as soon as normal conditions are restored.

Committee to Standardize Petroleum Specifications Asks State Co-operation

WASHINGTON, Feb. 24—In appealing to the Governors of the various States for co-operation in standardizing petroleum specifications for the entire country, letters have been sent to the Governor of each State containing memorandum as to the laws for gasoline inspection in each State along with the bulletins issued by the Committee on Standardization of Petroleum Specifications. This committee has been investigating the subject for months, and a series of standards are gradually being developed which are put out from time to time in bulletin form.

EXPORTS OF PASSENGER AUTOMOBILES IN 1914 AND 1918

Country	Twelve months Ended Dec. 31, 1918 No.	Value	Twelve months Ended June 30, 1914 No.	Value

	10,308	$26,814,952	784	$1,181,611

According to the committee, the variety of standards prevailing in different localities tends to raise the price of gasoline and other petroleum products for the consumer. Common standards, it is believed, would also improve quality. In this communication to the State Governors it is also pointed out that although the Fuel Administration will cease to function after peace is declared, the Committee on Standardization of Petroleum Specifications will continue for six months after that time.

U. S. May Now Ship to Finland

WASHINGTON, Feb. 25—Arrangements have been made by the War Trade Board whereby both export shipments and import shipments from Finland can be resumed. All shipments for export to Finland must be governed by the import certificate issued by the Inter-Allied Trade Committee at Helsingfors. Exporters should apply for licenses to the Bureau of Exports, Washington, but before filing applications must have advice from the prospective importer in Finland that a certificate has been issued by the Inter-Allied Trade Committee approving the proposed consignment.

St. Louis Show Huge Success

ST. LOUIS, Feb. 22—Judging by the attendance, the twelfth annual auto show being staged here at the Exhibit Building is a remarkable success. All past records have been broken. Facilities had been arranged to handle 16,000 people at the doors and the great crowds caused a call for special police details. More than 20,000 people clamored for admission.

Change in Post-War Exports Expected

Truck Exports to Decrease, Passenger Car Exports to Grow

NEW YORK, Feb. 24—That a radical change may be expected in the exportation of passenger cars and trucks with the ending of the war is the view of the National Automobile Chamber of Commerce. During the war, it is pointed out, yearly exports of cars more than doubled over the pre-war shipments, due to the inability of European makers to meet export demands. A much more pronounced effect, however, was noticeable in motor truck exports, which averaged 13,300 per year with an average value of $42,500,000 as against 888, valued at $1,459 for the fiscal year ended June 30, 1913 and 1914.

As the military demands of Europe greatly increased the truck shipments, it is now anticipated that there will be a drop that will bring truck shipments near their former proportion to passenger car exports.

A report of motor vehicle exports to all countries during 1918 shows that 10,308 trucks, valued at $26,814,952, and 36,936 passenger automobiles, valued at $36,278,292, were shipped abroad last year. In the fiscal year ended June 30, 1914, the last 12 months' period before the war, we exported only 784 trucks, worth $1,181,611, and 28,306 passenger automobiles, worth $25,392,963.

Analysis of the exports in 1918, as compared with 1914, shows that while the exports of passenger cars to England, France, Germany, Russia and British South Africa decreased notably and increased only slightly in Australia, they doubled to Canada, increased 28-fold to Japan, 12-fold to Mexico, nearly 9-fold to Chile and Spain, 6-fold to Cuba and China, more than 7-fold to Uruguay, more than quadrupled to the Dutch East Indies and almost doubled to Argentina.

Of the truck exports last year, on the other hand, more than half of the 10,308 went to England and France alone, while in 1914 less than one-third of the 784 shipped abroad went to these two.

M. A. M. A. Closes Washington Office

WASHINGTON, Feb. 24—The Motor and Accessory Manufacturers' Association office here was closed to-day, and R. M. McConnell, who has been in charge of it, is returning to Detroit. The office was a temporary one used chiefly to keep in touch with the Congressional action in the matter of the "Bill to Pay Informal Contracts."

Ontario to Build Roads

TORONTO, Feb. 24—The Ontario Government will spend $5,000,000 on highway construction this year. This means that with federal aid $8,333,333 will be expended for roads in Ontario this year.

British Aero Mfrs. Society Permanent

All Makers Are Members of Society of British Aircraft Constructors

LONDON, Feb. 2—One of the war organizations which will take its place as a permanent organization of peace days is the Society of British Aircraft Constructors formed in the early months of 1916, when aircraft manufacture was taking on the stature of an industry, and when it was apparent that all makers engaged in different phases of the work must co-operate to the fullest extent to give the necessary output of aircraft.

To-day every maker of aircraft in Great Britain is a member of this society. The list includes not only the makers of planes and engines, but those producing parts, dope, materials, steel in all forms, textiles, etc. There is no rivalry between those firms who before the war represented the aircraft industry on the one hand, and those new firms born of the war, that have become the greatest producers of aircraft.

There are two grades of membership: Poll members, made up of manufacturers of planes and engines; and associate members, representing makers of parts, materials, etc. Steel and aluminum makers also have membership in the society.

In the plan of organization the Committee of Management, composed of 14 members, manages the society. The membership is divided into sections according to manufacturing interests. Thus there is the dope section, the engine section, metallurgical section, etc. One section, known as Aerial Transport, has as its specific task all matters relating to aerial navigation. The government consults this section whenever it wishes advice from the manufacturers.

So far it has been impossible for the society to take any action relating to cross licensing of patents, as the government took over all aircraft patents in the early days of the war and still controls them. It is not known what action regarding patents may be taken when government control is released, if it ever is released with reference to patents.

The society has left the entire work of aircraft standardization in all its ramifications to the British Engineering Standards Committee, which is the final authority on all work relating to standardization in the British Empire. No manufacturing specification becomes a standard until so designated by the B. E. S. C. All standards for all industries come under its control. The actual steps in arriving at different standards are largely carried out by the members of the industry concerned, but the approval of any specification as a standard must come through the B. E. S. C.

During the war the society had little to do with government contracts except to work for their uniformity, and if manufacturers had complaints with reference to them these reached the government through the channels of the society rather than by direct representation of the manufacturer concerned.

—

French Racers for Indianapolis

PARIS, Feb. 21 (Special Cable. Delayed in Transit).—René Thomas, Albert Guyot and Bablot will race at Indianapolis on May 31.

Guyot drove one of the Sunbeams on the occasion of its first appearance in this country in 1913. The following year he came in third, driving a Delage, at Indianapolis. On his discharge, the result of wounds received, from the French Army, in which he saw active service as an airplane pilot, he entered into partnership with N. Causan and engaged in the profession of consulting engineer. The partner, who collaborated to produce successful car and boat engines for the Delage Co. and others, is particularly interested in racing and aviation development.

—

Ready for S. A. E. Air Meeting

Will Discuss Commercial Future of Airplanes, Aircraft Radiators and Dirigibles

NEW YORK, Feb. 25—The program for the meetings of the Society of Automotive Engineers, to be held in conjunction with the Aeronautical Exposition on March 7, is practically complete, and will include afternoon and evening sessions with a dinner at 6.30 p. m. The meetings and dinner will be held at the Engineering Societies Building, 29 West Thirty-ninth Street.

The afternoon session will include a paper on the commercial future of airplanes from the engineering standpoint by C. H. Day, chief engineer of the Standard Aircraft Corp.; a paper on aircraft radiators by Archibald Black of the United States Navy and former chief engineer of the L. W. F. Engineering Co., and a paper on dirigibles by Ladislas d'Orsy, editor. Pictures will be used to illustrate the discussions.

The dinner, which will be given at 6.30, is particularly intended to afford the members to become acquainted with one another and to allow for informal discussions on aviation. The evening session following the dinner will include addresses by officers of the United States Army and Navy and members of the automotive industry, whose names cannot yet be announced, as the evening program is not definitely completed.

The S. A. E. is also conducting an exhibit at the Aircraft Exposition on standards.

It is expected that there will be a large attendance at these sessions, when C. H. Manly, the newly elected president, will preside.

Auto Export Chiefs Will Meet

To Discuss All Pertinent Questions of Foreign Trade—Addresses Already Scheduled

NEW YORK, Feb. 25—A convention of automobile export managers will be held in the city March 7 under the auspices of the National Automobile Chamber of Commerce. Foreign trade opportunities, foreign credits, service abroad, packing for foreign shipments and the effect of the revenue bill on exports will be among the many subjects discussed. The meeting is being held as a result of the numerous export problems now facing the industry, and because of the new and unparalleled foreign conditions which are so intricate that co-operative discussion and action are made necessary.

Addresses already scheduled for the convention include:

"Trade-Marks in Foreign Countries." By James L. Stuart, of Stuart & Perry.

"What Our New Ships Can Do for Exporters." By Ira Campbell, U. S. Shipping Board, Washington.

"Definite Things We Must Do to Advance Export Trade." By Roy S. McElwee, Assistant Chief, Bureau of Foreign and Domestic Commerce, Department of Commerce.

"How to Use the Webb-Pomerene Law Providing for Combination of Competitors for Export Selling." By Allen Walker, Mgr., Foreign Trade Dept., Guaranty Trust Co.

"Automobile Publicity in Foreign Lands." By Peter S. Steenstrup, Export Manager, General Motors Export Co.

"Straight Side Tires and Right Hand Drive for Foreign Markets." By D. B. Richardson, Export Manager, Studebaker Corporation.

"Financing Foreign Trade." By G. A. O'Reilly, Foreign Trade Representative, Irving National Bank.

The meeting will be at the direction of the Export Committee of the N. A. C. C., which includes J. Walter Drake, chairman, Hupp Motor Car Co.; H. M. Robins, Dodge Brothers; D. B. Richardson, Studebaker Corp.; B. S. Steenstrup, General Motors Corp.; J. Rathburn, White Co., and R. T. Williams, Willys-Overland Co.

—

Mexican Oil Imports Increase

WASHINGTON, Feb. 24—Regardless of embargoes and other restrictions imposed by the Mexican Government, oil imports from there to the United States are steadily increasing, according to the Department of Commerce. During the period between July 1 and Jan. 13 last, crude oil imports from Mexico amounted to 1,060,615,650 gal. and refined to 26,744,049, valued in total at $15,500,000. This was a greater amount than the imports for the entire year 1917.

—

Tax Mexican Parcel Post Imports

WASHINGTON, Feb. 22—The Mexican decree of Jan. 7 provides a special surtax of 15 per cent of the respective customs duties on all goods imported or exported by parcel post.

England Standardizes Steels

Institution of Automobile Engineers Evolving Complete Standards Program

LONDON, Feb. 4—With the signing of the armistice activities connected with the Institution of Automobile Engineers have taken on renewed interest. In the first days of war the institution's work was greatly hampered. In fact, it was throughout the war, but the organization was maintained, and a more or less depleted office force carried along.

A monthly schedule of meetings has been drafted and carried out. The attendance at the last two meetings was greater than at any previous meetings during the war. Meetings are held on the 5th of each month.

The program for the remainder of the winter and spring season follows: Feb. 5, "Efficient Invention," by Douglas Leechman, a leading patent attorney and agent; March 5, "Lubrication," by Capt. G. W. A. Brown of the Arrol-Johnston Co.; April 5, "Electric Vehicles," by Carl Opperman, who has been closely associated with electric vehicle matters for many years; May 5, "Diesel Engines," by J. Day of Mirrless, Bickert & Day, makers of Diesel engines. At the Jan. 5 meeting L. H. Pomeroy's address on "Valve-in-the-Head Engines" was heard by over 200 members and guests.

The war almost completely disrupted the standardization program of the institution, but since Nov. 11 the go-ahead has been given, and a comprehensive committee organization has been created and pushed into action.

Standardize 20 Automobile Steels

The 100 per cent turning of the automobile industry to electric lighting and starting has called for quick standardization decisions on all such apparatus. The work on battery standardization has just started. The holding of a preliminary meeting represents accomplishments to date. It is quite certain that plate dimensions will be standardized, and the desire is to work as closely with American standards as possible.

With electric starting motors outside dimensions are going to be standardized. The committee is under way in this work. No decisions with regard to electric generators have been made. The committee has not yet started work on this. A committee is working on carbureter flanges, but as yet it is not very active and little progress has been made.

The greatest standardization work accomplished to date is that on 20 different automobile steels. All of the research work on these has been done and the specifications decided upon as well as the physical tests each must meet. In this work the steel manufacturers co-operated to the fullest extent with the automobile engineers. In 11 months from the start of the work it was completed, and by that time ten of the standard steels were in production by the steel men. The specifications of these steels appeared in a recent issue of AUTOMOTIVE INDUSTRIES.

In tire standardization much work has been done, but as yet Great Britain has more standard sizes than the United States. The sentiment in the I. A. E. is to still further reduce the number of sizes and if possible adopt the same standards as in America. Standardization work on magnetos and spark plugs has been completed.

The final adoption of any standard does not rest with the I. A. E., but with the British Engineering Standards Committee, an organization for standardization which represents all British industries, and whose approval is necessary before any standard in any industry can be officially recorded.

The automobile industry works through the B. E. S. C. in all standardization. In fact, the preliminary work is all done by committees of the I. A. E. and other automobille organizations. There is what is known as the Technical Committee of the Motor Industry, which is composed of representatives of three leading industrial groups, namely, (a) the Institution of Automobile Engineers, (b) the Society of Motor Manufacturers and Traders, (c) the Association of British and Allied Manufacturers, (d) representatives of other concerned organizations. This Technical Committee does the preliminary investigating work on any standard, and presents its conclusions to the B. E. S. C., which takes action as seems best.

Resumption of Trade with Bulgaria, Turkey and Black Sea Ports

WASHINGTON, Feb. 24—The War Trade Board has authorized trade and communication between this country and Bulgaria and the Turkish Empire, both in Europe and Asia Minor, subject to its rules and regulations. Russian Black Sea ports, Roumania and all ports on the Black Sea are now open to trade with the United States.

Applications will be considered for licenses to export and import all commodities to or from such territory.

The War Trade Board has received no official statement as to what the import regulations into this territory, if any, will be. Prospective exporters should therefore communicate with their customers abroad before making shipments, to comply with any import regulations that may be in effect.

U. S. May Now Ship to British Guiana

WASHINGTON, Feb. 25—Proclamations which restricted the importation of motorcycles and side cars, motor cars, including spare parts, farm tractors and trucks into British Guiana from the United States, have been revoked, according to a consular report. This revocation removes all restrictions on imports that were enforced in British Guiana during the war.

New Line of Hinkley Heavy-Duty Engines

Truck and Tractor Types Built on Design Standards of Class B Army Model

DETROIT, Feb. 24—The Hinkley Motors Corp., Detroit, is now producing a line of truck and tractor engines built around the standards of design and workmanship employed in the construction of the class B government engine. These are known as the Hinkley class B. In addition, models HA and HAA are built along similar lines, and show the same characteristics with reference to appearance and performance.

The line is rated at 55 hp. at 1400 r.p.m.; 45 hp. at 1500 r.p.m. and 35 hp. at 2000 r.p.m. for the respective models, and the engines are respectively suitable for 4-6 ton, 3-4 ton and 1½-2½ ton trucks, or 4 plow, 2-3 plow and 1-2 plow tractors.

The class B military engine has been described frequently and the Hinkley class B is similar in all essential respects. It is a 4¾ x 6-in. job with block cast cylinders. Model HA is 4½ x 5½ in. and is constructed along similar lines to the class B. Model HAA is 3¾ x 5¼ and is also adapted for cylinders of 4 in. bore for the purpose of being used with a maximum load capacity truck of 2½ tons. Detailed specifications and illustrations will appear in an early issue of AUTOMOTIVE INDUSTRIES.

New English Motorcycle

LONDON, Feb. 10—A motorcycle produced by the Sopwith Aviation Co., Ltd., which first made its appearance before the war, is now being put on the market. Because of the war, work on this machine, the A. B. C., was stopped, while the company centered its efforts on aviation design.

The frame of the new machine is suspended on long leaf springs, both fore and aft. In the rear the chain stays are pivoted on roller bearings. At each end the springs are rigidly clamped, giving the effect of the cantilever pattern. A horizontally opposed 3 hp. twin-cylinder engine sets across the frame and is bolted to an aluminum gearbox, giving four speeds controlled by a gate lever. The flywheel and clutch are also enclosed, the drive being taken care of through bevel pinions and a slow-running chain to the back wheel. An elastic coupling in the driving sprocket absorbs any snatch in the transmission.

A positive lubrication system supplies both the gear and the engine, the oil being contained in a common pump. The valves are in the cylinder heads, which are of cast iron, and detachable. The cylinders are turned with their cooling ribs from the solid steel billet. Pistons are of aluminum alloy. The connecting rods have roller bearings running on a hardened crankshaft.

Road Builders Hold Annual Convention

Proceedings Based on Principle That the Motor Truck's Needs Are Paramount

NEW YORK, Feb. 26—As this issue of AUTOMOTIVE INDUSTRIES goes to press, the sixteenth annual convention of the American Road Builders' Association is holding its daily sessions at the Hotel McAlpin.

Although the convention is far from its close, a number of fundamental principles have been laid down. First and foremost, the general consensus of opinion tends very strongly to the axiom that roads must be built with due regard to the strains and stresses imposed by heavy automotive traffic. It has been, and is being, emphasized in no uncertain way that the motor truck is the king of the road, and that it is imperative that not only main highways but connecting roads shall be so constructed as to be fully capable of standing up under intensive motor-propelled traffic.

Highway engineers who may have hitherto considered road problems on a horse and wagon basis are now obviously fully alive to the fact that mechanical road transport has arrived, and whether they may be advocates of bitumenized or brick surfaces or cement or macadam foundations they have adapted themselves to the new order in no half-hearted way and, without exception, have declared themselves staunch supporters of whatever type of highway is most suitable for the truck.

Evidence of the realization of the coming of the motor truck as the standard method of highway transport was given over and over again. For example, the Hon. Francis M. Hugo, Secretary of State for New York, stated that it was with a full realization of the importance of the motor truck that appropriations covering road construction for the present and future years were made and that, moreover, 90 per cent of the increase in 1918 registrations for the State of New York were accounted for by the increase in the number of commercial motor vehicles in service.

National Tractor Demonstration for Wichita

KANSAS CITY, Feb. 27—The Demonstration Committee of the National Implement and Vehicle Association has decided on Wichita for the 1919 National Tractor Demonstration, to take place some time in July. No definite date has yet been fixed. Exhibitions for Walla Walla and Macon have also been given official sanction.

Industrial Board for Price Readjustments

WASHINGTON, Feb. 27—The Industrial Board of the Department of Commerce has been formed, composed of representative men from industry, labor and the Government, who are being selected under the chairmanship of George N. Peek, formerly vice-chairman of the War Industries Board. They are to put into practical effect a program for the readjustment of prices for basic materials in such a fashion as to create a firm foundation on which the consumer can base his future purchases, and the producer can form necessary estimates. The Industrial Board has the assistance of the Council of National Defense.

President Signs Tax Bill

(*Continued from page* 495)

competes with rail or water express and a tax of 8 per cent of the transportation fee for carrying of passengers by motor truck, passenger car or motorcycle when it is in competition with rail or water carriers.

There is no floor tax or tax on motor fuels in the new Revenue act signed by the President Monday nor is there direct tax on car users except that persons carrying on the business of operating or renting passenger automobiles for hire are taxed $10 annually for each automobile seating more than one or less than eight passengers, and $20 a year for automobiles seating more than seven.

The tax situation regarding the exporting of automobiles, tires, parts and accessories therefor, is changed, so that under the new law, all such articles "sold or leased for export and in due course exported," are not subject to the tax. This is in compliance with the Federal Constitutional provision against taxes on exports.

There are some complicated provisions in section 1312 of the new law to the effect that on contracts for the sale or lease of cars and parts, etc., made prior to the date when this new law was first discussed in Congress, the purchaser or lessee must reimburse the seller or lessor for the tax that the latter has to pay.

Those liable for the tax on automobiles, tires, parts and accessories, must make monthly returns under oath in duplicate, to the local collector of Internal Revenue and pay the taxes due to this collector without further notice. If the tax is not paid when due, there is added a penalty of 5 per cent together with interest at 1 per cent per month.

Although it will be obligatory to report outputs of cars, trucks and accessories for each month on the last day of the month, manufacturers are being granted a 30-day grace for the few days between Feb. 25 and March 1, and do not need to report their output for these several days until the last day of March, when the reports can be turned in with the statements of March outputs.

The tax on automobiles, tires, parts and accessories becomes due when the article is sold or leased. This means, in the case of sales, when the legal title passes from the buyer to the seller or when the article ceases to be the property of the seller and becomes the property of the buyer, and in case of a lease, the lease is effective generally when the lessee receives possession of the article. Therefore, all sales and leases by automobile manufacturers and accessory manufacturers made on and after Feb. 25 are subject to the tax rates of the new law. All sales and leases made prior to Feb. 25 are either tax free or subject to the old tax rate, as the case may be.

Tax for Trucks In Canada

Fear Multiple Taxation by Different Municipalities—Not on Own Business Use

MONTREAL, P. Q., Feb. 25—An amendment to the Motor Vehicle act of the Province of Quebec gives municipalities power to tax commercial motor vehicles and horse-drawn vehicles and truck owners fear that the authorities may neglect to provide distinctly that an owner of a commercial motor vehicle be only taxed by one municipality. Owing to the fact that the saddling of this tax by municipality is entirely optional, a motor owner might own several commercial vehicles in an adjoining municipality which did not levy a tax, yet that owner might use the streets of Montreal or of another municipality far more than those of his own municipality and, therefore, it would be manifestly unfair that he should go absolutely untaxed. On the other hand, provided that all municipalities take advantage of this amendment the burden upon the owner of the vehicle would be very heavy if he were called upon to pay a tax in every municipality in which he operated. Owing to the fact that motor vehicles are designed to cover long distances and comparatively few of them operate within a single municipality, it is felt that if the scope of this amendment is not clearly and definitely outlined in its construction that this clause may lead to confusion and hardships.

The amendments that are to be made to the motor vehicle law to allow municipalities to levy a business tax on motor vehicles by the Legislature will not apply to those firms who use automobiles, whether they be trucks or light delivery vans, for their own business, unless they be cabmen or common carriers.

Firms who use motor vehicles for delivering orders, such as the big department stores, will not have to pay any municipal tax, but only their provincial license fee. Those who use their trucks for hire, such as cartage and express companies, will, however, come under the Act, and will be liable to a tax by the municipality within whose limits they have their place of business, and not be liable to a tax by any other municipality within whose limits they may travel in the course of their business.

There is nothing specified in the bill as to the amount of this tax, but this will probably be amended so as to ensure that municipalities shall not charge a business tax greater than that specified for a 4-wheeled wagon with two horses, which is $12 for general carriers.

Kelly-Springfield Gross Profits, $7,187,834

NEW YORK, Feb 21—Gross profits of the Kelly-Springfield Tire Co. for the year ended Dec. 31 amounted to $7,187,834, as against $4,323,955 for 1917, and the surplus after dividends were paid was $2,939,992, an increase of $1,486,407 over 1917. The general surplus of $9,197,858 is an increase of $3,492,226 over $5,705,632 in 1917.

The company's balance sheet for the past two years follows:

Assets	1918	1917
Cash on hand	$1,392,729	$772,448
Accounts receivable	1,467,296	1,748,346

General surplus	9,197,858	5,705,633
Total	$19,147,995	$15,395,835

Jordan Dividends

CLEVELAND, Feb. 24—A dividend of $3.50 per share to stockholders of record Jan. 31 was declared at the meeting of the board of directors of the Jordan Motor Car Co., on Feb. 12. The total production for 1918 was about 300 cars less than 1917. The following officers were elected for the ensuing year: President, Edward S. Jordan; vice-president, T. E. Barton; secretary and treasurer, Paul Zens. Besides the officers, the directors include Russell S. Begg and P. H. Withington.

Dunlop Profits $3,250,000

LONDON, Feb. 12—A large increase in profits is reported by the Dunlop Rubber Co., which held its twentieth annual meeting yesterday. A gain of $1,057,000 over 1917 profits was made by the company last year, the profit being $3,250,000, compared with $2,175,000 in 1917. The profits for 1918 were stated to be the largest in the history of the company. The company did not include in this statement of profits a sum of approximately $1,625,000 which has been retained for development and as additional working capital in the rubber estates and subsidiary companies and for the special plant and buildings depreciations. Thus, the actual earnings for the year are brought up to $4,875,000.

The solid tire business showed a large increase, amounting to nearly 60 per cent. The company is now planning new additions to increase its production. The new works at Fort Dunlop are in the process of enlargement. Approximately $2,000,000 will be expended by next August on these additions and it is expected that the pneumatic tire production will as a result be increased doubly and the solid tire production about 50 per cent.

The retiring directors and auditors were re-elected and Sir Arthur de Cros, chairman and managing director, was elected for life as president. Alfred de Cros has been nominated as vice-president. Harvey du Cros, the founder and president of the company, died during the war.

Goodrich Sales Increase 41 Per Cent in 1918

AKRON, Feb. 24—Net sales of the B. F. Goodrich Co. for 1918 amounted to $123,470,188, an increase of $36,315,116 over the $87,155,072 sales in 1917. After deducting for bills payable, taxes, etc., a net profit of $15,637,115 remained, $5,092,437 more than for 1917. After dividends were taken off the surplus was $10,442,609, against $5,257,491 in 1917.

The balance sheet of Dec. 31 last, compared with that of 1917, shows:

Assets	1918	1917
Real estate, etc	$74,859,587	$76,381,661
Investments	5,206,363	4 410,002
Pref'd treasury stock	930,700	865,700
Inventories, accounts receivable, cash, etc.	59,795,520	63,499,294
Deferred charges	446,258	970,589
Total	$141,238,427	$146,127,246
Liabilities		
Capital stock	$85,500,000	$86,400,000
Accts. payable	16 770,900	33,649,867
Reserve	3,847,540	2,300,000
Appropriation for redemption of pfd. stock	......	3,600,000
Surplus	35,119,988	20,177,379
Contingent liabilities.	501,117	655,768
	$141,238,427	$146,127,246

National Sales $2,880,757

INDIANAPOLIS, Feb. 24—Net sales of the National Motor Car & Vehicle Corp. totaled $2,880,757 last year, according to its report for 1918. After deducting $2,395,793 for cost of sales, gross profits of $484,964 remained. Operating expenses and reserve equalled $236,502, miscellaneous income $18,325, and gross income $266,787. Subtracting interest amounting to $63,178 and $65,000 for income and war taxes, the net income was $138,609.

Detroiters Organize New Foundry Co.

DETROIT, Feb. 21—The D. J. Ryan Foundry Co., of Ecorse, Mich., has been organized and purchased the property of the Ecores Foundry & Machine Co. The capacity of the plant will be doubled. The manufacture of motor castings is now going on at full speed. D. J. Ryan is president of the company. Other officers are: Vice-president, Louis J. Felton; secretary, R. J. Lamb, and treasurer, Chester A. Trathen.

Bower Bearing Co. Surplus $299,073.55

DETROIT, Feb. 24—The Bower Roller Bearing Co. reports a surplus of $229,073.55 on Jan. 1. The capital stock is $600,000.

Hayes Wheel Co.'s 1918 Sales Total $7,655,249

NEW YORK, Feb. 26—Government contracts, increased maintenance and depreciation costs, and a falling off in production as a result of these contracts, are reflected in the financial statement of the Hayes Wheel Co., Jackson, Mich., for 1918. Notwithstanding these conditions, sales amounted to $7,655,249 on a production of 2,006,405 wheels, compared with sales of 3,571,681 wheels in 1917, valued at $8,674.370.

The falling off in number of wheels produced in 1918 was due to the output being partly of escort wheels for the Government, costing six to seven times more per wheel than automobile wheels. Escort wheels were not made after December, 1918. The company is now back on a peace basis and its production for 1919 is scheduled for more than 4,000,000 wheels.

Net profits for 1918 were $314,502, giving an average of $454,714 for the last three years, or 6½ times the $70,000 total annual requirements for interest on the $1,000,000 first mortgage bond issue. The company has an accumulated surplus of $822,673 and this added to its capital stock of $1,500,000 gives it an invested capital of $2,322,673.

The financial statement for the past two years follows:

Assets	1917	Jan. 31, 1919
Real estate, plant and equipment	$1,438,222	$1,429,794
Seourities	26,000	26,000
Accounts receivable	786,254	602,162
Inventories	1,400,130	1,704,508
Liberty bonds and cash value of insurance	60,400	39,156
Cash	393,953	412,333

White Dividends

White Motor Co., Cleveland, regular quarterly dividend, $1 per share, payable March 31 to stockholders of record March 15.

Fire Wrecks Wilson Body Plant

DETROIT, Feb. 22—The five-story brick assembly plant of the C. R. Wilson Body Co. burned to the ground Friday night. The loss, estimated at between $400,000 and $500,000, is covered by insurance.

Production will not be greatly handicapped. About 400 men are made idle by the blaze, but arrangements are being made to transfer them to the other plants of the company here and at Bay City. Assembly work will be shifted to other building units and the big plant will be operating normally again in a week or ten days.

Dorris Car Up $250

ST. LOUIS, Feb. 24—The Dorris Motor Car Co. has raised the price of its touring car from $3,500 to $3,750, to become effective March 1.

Moon Getting Back to Car Production

ST. LOUIS, Feb. 24—The Moon Motor Car Co. will resume production of automobiles March 15. Owing to the fact that it was engaged in shell work during the war, returning to motor cars was somewhat delayed. The new buildings, erected especially for shell work, will be equipped for motor car production.

Will Make 15,000 Hupps

DETROIT, Feb. 25—The Hupp Motor Car Corp. will produce 15,000 cars in 1919. This is an increase of 5500 cars over last year. During the last half of January this company ran up its production to forty cars daily, and further increase is contemplated.

Dorris Adds 3½-Ton Truck

ST. LOUIS, Feb. 22—The Dorris Motor Car Co. has added to its line a 3½-ton truck, styled model K-7, to sell for $3,800. The company's 2-ton vehicle sells for $2,985.

Allen on 1919 Production

FOSTORIA, O., Feb. 22—The Allen Motor Co. is getting into 1919 production and its schedule calls for the production of between 4000 and 5000 cars this year. With exception of refinements, the 1919 car differs only slightly from the standard 1918 model.

Johns-Manville Distributes 20 Per cent Bonus

NEW YORK, Feb. 21—The H. W. Johns-Manville Co. will distribute to all its salaried employees who were in continuous service for the full year, 1918, 20 per cent on the salaries paid them during that year. The company also did this for 1917. The extra compensation for 1918 will cost approximately $1,000,000.

2000 Clydes This Year

CLYDE, OHIO, Feb. 24—The Clyde Cars Co. plans to build 2000 trucks in 1919, which is double the 1918 output.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Moline-Knight Will Not Cut Price

MOLINE, ILL., Feb. 21—Moline-Knight dealers are being notified by the Root & Van Dervoort Engineering Co., makers of the car, that there will be no price decrease in the Moline-Knight during the present year. As an assurance that the present schedule will be continued, dealers are guaranteed refunds for their customers for the amount of any reduction that might be made before Jan. 1, 1920.

Moline Addition

MOLINE, ILL., Feb. 22—To take care of increased production, the Moline Plow Co. is adding a new 160 x 28 building to furnish more convenient shipping facilities. It will be utilized for storing the finished machines prior to shipment.

Willys Export Co. Formed

TOLEDO, Feb. 22—The John N. Willys Export Co. has been incorporated in Delaware with capital of $100,000 by John N. Willys and associates to engage in export work.

Miller Rubber Yearly Sales

AKRON, O., Feb. 24—The board of directors of the Miller Rubber Co. was re-elected and all other officials reappointed at the annual meeting of the company. Charles E. Wetzell was chosen assistant secretary. Inability of the auditor to submit a report made it necessary to omit the annual statement. It was stated, however, that the gross sales were over $16,000,000 in 1918, a 45 per cent increase over 1917.

Lee Tire Earns $30,000 More Than 1917

NEW YORK, Feb. 22—The Lee Rubber & Tire Corp. showed earnings of $250,000 for 1918, as compared with $220,000 for 1917, after all necessary deductions were made. Sales for January, 1919, are about 30 per cent larger than for the same month last year. Although the company's financial position is understood to be good, there is no prospect of a disbursement to the stockholders for some time.

Paige-Detroit Ahead of Schedule

DETROIT, Feb. 22—The Paige-Detroit Motor Car Co. is producing between 40 and 45 cars daily, which is a greater production than the January and February schedules called for. By March production will exceed 65 cars. This company, when the armistice was signed, was working 90 per cent capacity on war contracts, totaling approximately $15,000,000. About 60 per cent of these contracts were completed.

Cadillac Producing 60 Cars Daily

DETROIT, Feb. 24—The Cadillac Motor Car Co. has run its production up to 60 cars daily, and anticipates producing between 90 and 100 shortly. The 1919 production schedule will probably equal that of 1918, which called for 18,000 cars.

Standard Tool Co. Getting Back to Normal

DETROIT, Feb. 22—The Standard Tool & Mfg. Co. is getting back to peacetime production and is now running at 75 per cent capacity. This concern was engaged at its full capacity on war work up to the signing of the armistice.

9000 Commerce Trucks 1919 Output

DETROIT, Feb. 24—The Commerce Motor Car Co., makers of Commerce trucks, will build 9000 machines this year, according to their proposed production schedule. The company is turning out 20 cars daily, but will increase production 50 per cent within 30 days.

Appersons Ready for Delivery May 1

KOKOMO, Feb. 22—Owing to the postwar material situation, it was impossible to have the standard Apperson models ready in time for the various automobile shows. Deliveries on the open-body models are assured for May 1, but the enclosed models in both seven- and four-passenger types will not be ready till early fall.

Canadian Ford Guarantees Price

DETROIT, Feb. 24—The Ford Motor Co. of Canada, Ltd., states that 1919 will bring no change in the price of Ford cars. The prices follow:

Runabout	$660
Touring Car	690
Coupe	875
Sedan	1075
Standard Chassis	625
One Ton Truck Chassis	750

Dividends Declared by Goodyear

Goodyear Tire & Rubber Co., Cleveland, regular quarterly dividend, 3 per cent, common stock, payable March 1 to stockholders of record Feb. 15.

$1,800,000 American Bosch Notes Sold

NEW YORK, Feb. 22—The $1,800,000 American Bosch Magneto Corp. 7 per cent gold notes have all been sold.

Inter-State to Complete 15-20 Per Cent of War Orders

MUNCIE, IND., Feb. 24—The Inter-State Motor Co. will be required to complete 15 to 20 per cent of the Government order, and manufacturing will be continued with this end in view. At the same time the engineering and experimental departments are going ahead with modifications and improvements in the Model T chassis which has a four-cylinder engine. The service department has been re-established.

Rickenbacker Back in Civil Life

NEW YORK, Feb. 25—Capt. Ed. V. Rickenbacker has received his honorable discharge from the army and has returned to this city. Although the American ace of aces has received attractive offers from motion picture producers and from publishers he has not yet decided what business he will engage in.

—

Samuel E. Ryder, for a number of years in the employ of the Motometer Co., Long Island City, is now affiliated with the Detroit branch of the company opened recently.

—

W. B. Fowell has been appointed sales manager of the Stan-Par Axle division of the Standard Parts Co.

—

Frank M. Lee, manager of the Milwaukee branch of the Fisk Rubber Co., New York, has resigned after a term of continuous service of twenty-five years. He will go to California for a rest of several months.

—

Thomas W. Brickley has succeeded F. L. Warner as manager of the Milwaukee office of the Central Electric Co., Chicago.

—

G. M. Rymarczick, until recently supervising senior inspector of the magneto section of the Bureau of Aircraft Production, is now connected with the Simms Magneto Co., East Orange, N. J., as production engineer.

—

John B. Giovanoli, formerly with the Willys-Overland Co., has become tool superintendent of the Fuller & Sons Mfg. Co., Kalamazoo, Mich.

—

Captain A. E. Callanan has been appointed general purchasing agent of the Cleveland Tractor Co. He was formerly in charge of production of de Haviland battle planes at the Dayton-Wright Co., Dayton.

—

J. H. Hardig, formerly advertising manager of the Remy Electric Co., has been appointed assistant advertising manager of the motor equipment division of the United Motors Corp., Detroit.

—

E. H. Walker, for eight years Detroit district manager for the Vanadium-Alloys Steel Co., Pittsburgh, has resigned to become secretary-treasurer of the Michigan Metal Supply Co., Detroit.

—

R. J. Snowhook, for three years connected with the Willys-Overland Co., Toledo, Ohio, has joined the advertising department of the Nash Motors Co., Kenosha, Wis.

—

Lieut.-Com. Benjamin Briscoe of the Briscoe Motor Co., Jackson, Mich., has returned from Europe, where he was in charge of navy airplanes, air bases and supply depots.

Men of the Industry

Changes in Personnel and Position

Frank Jay Heads Stanley Motor Carriage

NEWTON, MASS., Feb. 25—Frank Jay was elected president and general manager of the Stanley Motor Carriage Co. at the annual meeting of the company held on Feb. 20.

—

Albert L. Jones, for twenty years with the White Co., is in charge of the assembling branch of the Fulton Motor Truck Co., San Antonio, Tex.

—

C. M. Strieby, former advertising and sales manager of the Smith Motor Truck Corp., Chicago, has been appointed advertising manager of the Fulton Motor Truck Co., Farmingdale, L. I. He was formerly connected with the Maxwell Motor Car Co. and with the Studebaker Corp.

—

Capt. Albert G. Waddell has returned to civil life and resumed his duties as advertising manager of the Chevrolet Motor Co., Oakland, Cal.

—

H. S. Quick has been appointed manager of the Chicago office of Robert H. Hassler, Inc., which has recently been opened at 2007 Michigan Avenue.

—

R. G. Ames has joined the Black & Decker Mfg. Co., Baltimore, as branch manager in charge of the Chicago office. For the past ten years he was with Edward A. Cassidy Co., New York.

—

Lieut. F. M. Young, formerly in the aviation service, has returned from overseas and is now sales engineer with the Perfex Radiator Co., Racine, Wis.

—

Detroit S. A. E. Officers Nominated

DETROIT, Feb. 26—W. A. Brush, of the Brush Engineering Association, has been nominated to head the Detroit section of the Society of Automotive Engineers for the season of 1919-1920, to succeed J. Edward Schipper of the Class Journal Co. E. G. Gunn, carriage engineer of the Packard Motor Car Co., has been nominated for the vice-chairmanship; E. W. Seaholm, Cadillac Motor Car Co., treasurer, and Ralph H. Sherry, metallurgist General Motors Co., secretary. The nominating committee consisted of D. McCall White, vice-president Cadillac Motor Car Co.; C. C. Hinkley, Hinkley Motors Corp.; O. E. Hunt, engineer Packard Motor Car Co., and Benjamin G. Koether, Hyatt Roller Bearing Co.

Lodge Heads Candler Radiator Co.

DETROIT, Feb. 25—The Chandler Radiator Co. held its annual meeting, at which the following officers were elected: President, John C. Lodge; vice-president, George V. Candler; secretary and manager, John A. Hinger; directors, A. V. Breault, George V. Candler, W. R. Candler, John A. Hinger, James S. Holden, John C. Lodge and D. E. Murray.

—

Stout With United Aircraft Corp.

NEW YORK, Feb. 25—W. B. Stout, formerly aircraft engineer of the Packard Motor Car Co., has been appointed sales and aircraft manager of the United Aircraft Engineering Co., New York.

—

Col. Edwin S. George has been honorably discharged from the Army, where he acted as chief of the motors branch of the Motors and Vehicles Division, office of Director of Purchase and Storage. He has joined his family in Miami, Fla., and will return to Detroit in April.

—

Harmon J. Kline, formerly designing engineer for the Olds Motor Works, Lansing, has been released from the service, where he was a lieutenant in the Ordnance Department, and has joined the engineering staff of the Packard Motor Car Co.

—

Bruce J. Miles, formerly with the Cadillac Motor Car Co., has been made manager of the sales department of the Cadillac unit of the General Motors Export Co., New York City.

—

Joseph C. Faust, director of the production of advertising art for the Packard Motor Car Co., has resigned to become associated with Voelker & Scharfenberg, advertising agency.

—

A. E. Wingert, for three years connected with the sales department of the Chalmers Motor Co., has resigned, effective March 1. He will announce his future plans shortly.

—

C. F. Troupe, who represented the Fisk Rubber Co. in the East and South, has succeeded Frank Lee as sales manager of that company in Wisconsin and upper Michigan.

—

C. S. Puttman has been appointed manager of the Detroit branch of the United States Tire Co. He has been with that company since 1911.

—

Collier Annual Meeting

BELLEVUE, OHIO, Feb. 22—At the annual meeting of the Collier Motor Truck Co. on Monday, the following officers were elected; President, R. A. Palmer; vice-president, S. H. Penfield; secretary and treasurer, J. F. Corl. M. E. Crow has resigned. Otherwise the Board of Directors was re-elected, including the officers and F. W. Steinen and Charles Matz.

AUTOMOBILE SHEET PRICES

(Based on No. 22 Gage. Other gages at usual differentials)

	Primes only per 100 lbs.	Primes when seconds up to 15 per cent are taken per 100 lbs.
Automobile body stock	$5.95	$5.85
Automobile body stock, deep stamping	6.20	6.10
Automobile body stock, extra deep stamping	6.45	6.35
Hood, flat, fender, door and apron, or splash guard stock	6.05	5.95
Crown fender, cowl and radiator casing, extra deep stamping	6.55	6.45
Crown fender, cowl and radiator casing, deep stamping	6.30	6.20

Automobile Sheet Extras for Extreme Widths:
Nos. 17 and 18 over 36 in. to 44 in., 10c. per 100 lb.
Nos. 19 and 21 over 36 in. to 44 in., 30c. per. 100 lb.
Nos. 22 to 24 over 26 in. to 40 in., 40c. per 100 lb.
Nos. 22 to 24 over 40 in. to 44 in., 80c. per 100 lb.

Blank Sheet Extras to Apply to Narrow Widths:
Oiling, 10c. per 100 lb.
Patent leveling, 25c. per 100 lb.

Resquaring, 5 per cent of gage price after quality, finish and size extras have been added.

Seconds 10 per cent less than the invoice Pittsburgh price for corresponding primes.

FOREIGN TRADE OPPORTUNITIES

WASHINGTON, Feb. 21—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has inquiries for the agencies of automobiles and tractors. Full information regarding each of the following can be secured by addressing the Bureau of Foreign and Domestic Commerce, Department of Commerce, and referring to the foreign trade opportunity number.

A firm in India desires to purchase and to secure an agency for the sale of motor cars, tires, tubes and accessories. References have been filed. Foreign Trade Opportunity No. 28,449.

A commercial agency in Honduras desires to represent firms for the sale of farm tractors. Quotations should be made f. o. b. American port. Correspondence may be in English. No. 28,452.

A firm in Italy desires an agency for the sale of farm tractors for work in the mountains as well as on the plains. Correspondence may be in English. References have been filed. No. 28,440.

A company in England desires the sole agency for the sale of automobiles. References have been filed. No. 28,441.

A Belgian importer in England desires an agency for the sale of bicycles, motorcycles, automobiles and tractors. References have been filed. Foreign Trade Opportunity No. 28431.

A man in England wishes to secure an agency for the sale of farm tractors in England and France. References have been filed. No. 28434.

A company is Switzerland wishes to secure an agency for the sale of farm tractors, motor trucks and accessories. No. 28437.

A man in Australia desires an agency for the sale of motor car accessories. References have been filed. Foreign Trade Opportunity No. 28,414.

An agency is desired by a man in Belgium for the sale of motors, automobiles and trucks. No. 28,417.

A firm in Denmark desires an agency for the sale in Poland of automobile accessories. Correspondence may be in English. References have been filed. No. 28,419.

A commercial agent in France wishes to secure an agency for the sale of farm tractors. Correspondence may be in English. References have been filed. No. 28,420.

New Models and Strong Parts Show at Kansas City

(*Continued from page* 494)

ciated with four-wheel-drive is avoided by steering on creeper type; that is by applying a brake to one or the other of the differential shafts. This plan obviates the need for extra differentials and universal joints in the axle shafts. The advantage sought is to make all the weight available for traction.

Heretofore most tractors have been designed specially for use in plowing and other tractor work on the farm has been incidental. It is well known that most other farm operations, such as corn planting, harrowing, disking and hauling, mowers and binders, require much less power than the engine of the conventional three-plow tractor is capable of giving. Hence in doing this work the tractor operates at low efficiency, not only because the engine is running at partial load but more particularly because the power expended in moving the heavy tractor is not commensurate with the power called for by the implement.

Considerations of this nature have induced some makers to bring out tractors of one-plow capacity which, while somewhat at disadvantage in comparison with large machines as regards to plowing, are superior for other work. The lower first cost will make its appeal to the prospect. Single plow tractors are shown by Allis-Chalmers and Indiana.

Motor cultivators are shown in variety for the first time in both single and double-row types. The operator steers by steering wheel and guides the cultivator by pedals, a foot rest not unlike a stirrup being provided on the beams. It is difficult to see the possibilities of a single-row cultivator as its capacity is little greater than a horse one, but it is not necessary to feed it all the year in order to use it for one or two months.

The motor cultivator must necessarily be developed along with the tractor because the corn belt farmer cannot dispense with any of his horses so long as he cannot do both plowing and cultivating by motor. As the two principal crops of the country, corn and cotton, both need it in cultivation the possibilities of this field are enormous.

In conclusion, regarding exhibit of parts at the show, the tractor industry is much more fortunate than was the automobile industry at a corresponding state of its development, considering the variety of highly developed carbureters, magnetos and friction bearings and other standard components the tractor designer has to choose from, and the fact that the makers of these components are so strongly represented at the show indicates that they all anticipate a rapid growth of the tractor industry.

Entertains Directors of M. A. M. A.

NEW YORK, Feb. 25—Following the usual monthly meeting of the Motor and Accessory Manufacturers Association, C. E. Thompson, president, gave an informal dinner. H. M. Swetland, president of the Class Journal Co., as a guest of Mr. Thompson, talked of his European experiences during the war. He was much impressed by the stability and solidity of the English as based on the principle, "not how quickly but how well" can their plants turn out merchandise.

"Don't overlook the fact, too," said Mr. Swetland, "that the English have learned the value of quantity production, and are now prepared in many lines to produce on a quantity basis articles of high quality." Among other things he mentioned the conferences he attended with leading political and industrial leaders of France and England. He also told of his visit to the great allied fleet, where he was entertained by Admiral Sims, and graphically described scenes in devastated France.

Besides C. E. Thompson, president of the Steel Products Co., and H. M. Swetland, president of the Class Journal Co., there were present: E. H. Broadwell, first vice-president of the M. A. M. A. and vice-president of the Fisk Rubber Co.; E. W. Beach, president of the Manufacturers Foundry Co.; G. W. Yoeman, treasurer of the Continental Motors Corp.; E. P. Hammond, president of the Gemmer Mfg. Co.; C. W. Stiger, president of the Stromberg Motor Devices Co.; A. W. Copland, president of the Detroit Gear & Machine Co.; M. L. Heminway, acting manager, and Sidney S. Meyers, counsel for the M. A. M. A.

"Aviation Weather" Conditions Reported in England

LONDON, Feb. 11—The announcements of aviation weather conditions appearing daily in a local newspaper show to some extent the progress of British development of aviation commercially.

Forecasts are given on wind, direction and velocity in the upper air, together with reports of similar conditions the previous day. These cover Scotland, England, Ireland, Wales and the Midlands. Under the heading, "Flying Prospects To-day," readers are advised on wind velocity at certain elevations, visibility, cloud formations and other conditions affecting cross-country work within certain areas.

Under another heading, "Aviation Weather," a chart shows the wind direction and velocity in the above sections during the previous day, in the morning, noon and evening, at elevations of 1000 to 15,000 ft. Velocities are given in miles per hour. The cloud-level over the entire British Isles is also added.

A weather chart, supplied by the Meteorological Office, indicates air conditions, temperature, velocity and weather.

Grease Cups on Cadillac

In AUTOMOTIVE INDUSTRIES on page 249, Jan. 30 issue, the Cadillac car is mentioned as having oil shackle lubrication, whereas grease cups are used and not oil cups.

High Tariffs and Prohibition Hold Industry Back

(*Continued from page* 455)

shut out our low-priced cars unless she is prepared to manufacture such vehicles herself for her tens of thousands who who want them. Her public will not permit of it. The British public, for example, may abide by such prohibition for a time but no government can withstand such a prohibition for long.

In this whole situation of our high tariffs and Europe's prohibition there is too much of the old story of "one's afraid and the other dare not."

Let us grant that European nations who have been at war for 4 years have a right to a period of protection, particularly for the types of cars they make, but should they endeavor to prohibit what they cannot produce and what in many cases they are not contemplating producing.

Europe is not going to the class of production that America has built her reputation on and neither is America going to the class of high-grade workmanship that characterizes European factories in the majority of her production jobs. The result on both sides will be a compromise. We will increase our quality and Europe will increase her production. There is enough room for all, but let us not hold back the market by political moves that serve the more selfish ends of a few but work generally against the good of the many.

The French Baby Renault Tank

(*Continued from page* 470)

men. A shell which will destroy a Renault 6-ton tank will usually eliminate a 35 or 40-ton tank. But the former, owing to its higher speed, greater handiness and smaller area, is much less liable to be hit than the latter. The personal element counts very considerably in the French army. There is no doubt that a certain weight of armament divided into twenty units, each one of these units being more or less independent and acting on its own initiative, will secure far better results than the same grouped into one or two colossal tanks. Great credit is due to Louis Renault for realizing this important fact.

Used to Haul Canal Barges

Since the signing of the armistice some of the Renault tanks have been made use of for hauling canal barges. Where two horses hauled one barge, a single Renault tank will haul three barges at 25 per cent increase in speed. The suggestion is also made that the tanks be made use of for agricultural work on heavy ground. They appear to be very suitable for this class of work if stripped of their heavy armor plating. The gasoline engine and the reducing gears are completely protected against dust and mud, and only one man is required to handle the machine.

Federal Highway Plan Outlined in Bill

(*Continued from page* 497)

necessary bridges, drainage structures, signs, guardrails, protective structures, and housing.

SEC. 2. That the commission shall consist of five members.

SEC. 3. That the commissioners shall be appointed by the President, by and with the advice and consent of the Senate; not more than three commissioners shall be of the same political party, and shall be chosen from different geographical sections of the United States.

SEC. 4. That the commissioners first appointed shall continue in office for the terms of three, four, five, six, and seven years, respectively, from the date of their appointment; the term of each to be designated by the President, but their successors shall be appointed for the term of seven years, except that any person chosen to fill a vacancy shall be appointed only for the unexpired term of the commissioner whom he shall succeed and have similar qualifications.

SEC. 5. That the commissioners shall receive a salary of $10,000 per annum, payable in the same manner as the judges of the courts of the United States.

SEC. 6. That the commission shall choose a chairman from its own membership. It shall be the duties of the members of the commission to devote the entire statutory time required of other governmental officials to their work.

SEC. 7. That the commission shall appoint a secretary who shall keep a journal of proceedings, minutes of each meeting, record all proceedings, make true copies of all notices to be published, and shall perform such other duties as the commission may designate and require.

SEC. 8. That it shall further have authority and power to employ, at a fixed compensation, a chief engineer, engineers, special experts, attorneys, and clerks as it may from time to time find necessary for the performance of its duties. All other employees of the commission shall be a part of the classified civil service, and shall enter the service under such rules and regulations as may be prescribed by the commission and by the Civil Service Commission.

SEC. 9. That the commission shall have an official seal which shall be judicially noticed.

SEC. 10. That a vacancy in the commission shall not impair the right of the remaining commissioners to exercise all the powers of the commission, and three members of such remaining commissioners shall constitute a quorum.

Shall Select Highways

SEC. 11. That the commission shall select from time to time, subject to such changes as it may deem advisable under the provisions of this act, the highways to be comprised in the National Highway System and shall determine the order in which such highway shall be constructed, reconstructed, and improved. In determining the highways to be comprised in the National Highway System the commission shall request the State highway departments to recommend the routes to be followed in their respective States. The National Highway System shall not include any highway in a place having a population, as shown by the latest available Federal census, of 5000 or more, except that portion of any such highway along which the houses average more than 200 feet apart.

SEC. 12. That the commission shall determine the types of construction and reconstruction and the character of improvement, repair, and maintenance of all highways included in the National Highway System, and shall direct, supervise, and control the making of the surveys, the preparation of the plans, specifications, and estimates, and the construction, reconstruction, improvement, repair, maintenance, and administration of such highways, or may arrange with the State highway departments in their respective States to make the necessary surveys and plans and to pay therefor. Only such durable types and adequate widths of surface shall be adopted for any highway as will effectively meet the traffic conditions thereon and the probable future traffic needs.

SEC. 13. That the Secretary of War may, in his discretion, deliver and turn over to the commission from time to time and without charge therefor, for use in the construction and maintenance of national highways, such vehicles, motor vehicles, road machinery, and equipment as may be suitable for the use of the commission; and the commission is hereby authorized to use the same, in its discretion, in the construction and maintenance of national highways, and to pay the necessary expenses thereof out of the appropriation made under the provisions of this act.

SEC. 14. That no money shall be expended in any State under this act until its legislature shall have assented to the provisions of this act, except that until the final adjournment of the first regular session of the legislature held after the passage of this act the assent of the governor shall be sufficient. In consideration of the benefits to be derived by the State from the construction, reconstruction, improvements, repair, and maintenance of the highways comprised in the National Highways System, and as a condition precedent to the construction of any such highways in any State a right of way therefor, not less than 60 feet in width, except at such points where existing buildings or structures are of such value that the cost of their removal would in the opinion of the commission be excessive, shall be furnished to the United States without expense to it by, for, or on behalf of such State or any civil subdivision thereof. Any land of the United States may be appropriated as rights of way for the highways herein provided for, and the consent of the United States is hereby given to any railroad or canal company to convey to the United States for such highways any part of its right of way acquired by grant from the United States. The highways comprised in the National Highways System shall be constructed, reconstructed, improved, repaired, maintained, and administered entirely at the expense of the United States, except State police powers, but the State or its civil subdivision shall maintain any such highway prior to the construction, reconstruction, or improvement thereof under this act.

Shall Regulate Use of Highways

SEC. 15. That the commission is authorized to prescribe and promulgate such regulations governing the use of highways comprised in the national highway system as the commission may find necessary and reasonable in order to preserve and protect such highways and to facilitate and insure the safety of travel and traffic thereon. Whoever shall wilfully or maliciously injure or destroy any part of a highway embraced in the national highway system or property or material owned or controlled by the United States in connection with such highway, or shall use any such highway or part thereof without complying with the regulations prescribed and promulgated by the commission hereunder, shall be fined not more than $1,000 or imprisoned for not more than one year, or both. Nothing in this act shall affect the jurisdiction of the State, either civil or criminal, over persons and property upon such highways, except so far as the regulation of the use thereof are concerned; that is to say, the State wherein any such highway is situated shall not, by reason of establishment thereof, lose its jurisdiction, nor the inhabitants thereof their rights and privileges as citizens, or be absolved from their duties as citizens of the State.

SEC. 16. That it shall be the further duty of the commission to encourage the proper use of all highways and to stimulate the interests of the States, communities, and rural districts in the most efficient and economical transportation over all highways in the United States, to ascertain by experiment and collect all data on new developments in highway transportation, construction, and maintenance, and to publish the same for the benefit of the people at large.

SEC. 17. That it shall be the further duty of the commission to take over and perform all duties, powers, functions, and other obligations of all Federal agencies having jurisdiction and control of highway and experimental road work and all Federal agencies of educational and investigative character relating to highway transportation. Said departments or agencies shall be so co-ordinated and consolidated as to be made most effective: *Provided, however*, That agencies dealing with all highways under control of the United States Army or Navy in military or naval reservations, or are used solely for military or naval purposes, shall not be so taken over, but shall remain under the jurisdiction and control of said agency.

SEC. 18. That, in addition to the authority conferred by the preceding sections, the commission is authorized to make all rules and regulations necessary for the efficient execution of this act. The commission may let to contract or perform in any other manner which it may deem proper any work under the provisions of this act.

SEC. 19. That, for the purpose of carrying out the foregoing sections of this act there is hereby appropriated out of any money in the Treasury not otherwise appropriated, $50,000,000, which shall become available July 1, 1919, and $75,000,000 for the fiscal year beginning July 1, 1920, and $100,000,000 for each of the three succeeding fiscal years; in all, $425,000,000, which shall be available until expended. Out of such appropriation there shall be available to the commission for each fiscal year, and until expended, such amounts as they may determine to be necessary for the payment of such administrative expenses, including such rent, printing and publications, the purchase of such supplies and equipment, and the employment of such persons and means, and the fixing of compensation therefor, in the District of Columbia and elsewhere, as may be deemed necessary for carrying out the provisions of this act. The amounts so made available to the commission may also be used for the erection and maintenance of buildings outside the District of Columbia and for the operation of housing and subsistence facilities and commissary stores, including the purchase and sale of commodities for the benefit of employees and others engaged upon work under this act, the receipts from such operations and sales to be credited to and become part of appropriation made by this section and to be available for expenditure in the same manner as the remainder of such appropriation. The commission is authorized to purchase, lease, rent, operate, and maintain such motor and other transportation facilities as it may deem necessary in performance of its duties under this act. The commission is authorized and empowered to issue permits, licenses, and franchises for openings in and the use of any portion of the right of way comprised in the national highway system, and may require such payment from the beneficiaries thereof, and in such manner as may seem equitable; and the receipts therefrom shall be credited to the appropriations made by this act, to be expendable in the same manner.

That the commission, after making the deductions authorized by this section, shall apportion the remainder of the appropriation for each fiscal year among the several States in the following manner; One-third in the ratio which the area of each State bears to the total area of all the States; one-third in the ratio which the population of each State bears to the total population of all the States as shown by the latest Federal census; one-third in the ratio which the highway mileage of each State bears to the total mileage of all the States as shown by the official bulletin issued by the Secretary of Agriculture for the year 1914; *Provided*, That if any State desires to immediately improve any section of the national highway within the State, which has been designated by the commission the commission may enter into an agreement with the State highway department of such a State to finance the construction or reconstruction of said highway or section thereof; *Provided, however*, That the amount so advanced shall not exceed the amount apportioned to said State for construction or reconstruction, and the commission shall authorize the repayment to the State highway department of the amount annually set aside for construction or reconstruction until the full amount so advanced has been repaid.

Authorized to Contract for Purchases

SEC. 20. That the commission is authorized to enter into arrangements with any public or private agency for purchase, easements, construction, installation, operation, and maintenance of any facilities which it may consider necessary in the use of the National Highway System, and to pay such part of the cost thereof out of the appropriations under this act as it may deem equitable.

SEC. 21. That in order to increase the effectiveness of an act entitled "An act to provide that the United States shall aid the States in the construction of rural post roads, and for other purposes," approved July 11, 1916, said act is hereby amended by enactment of the following provisions:

Section 2 of the act hereinbefore referred to is amended by striking out the word "may" and substituting therefore the word "can."

Paragraph 2 of section 6 of the aforesaid act is hereby amended by striking out the words "nor shall any such payment be in excess of $10,000 per mile, exclusive of the cost of bridges of more than 20 feet clear span."

SEC. 22. That for the purpose of carrying out the provisions of said act as herein amended, there is hereby appropriated, out of any money in the Treasury not otherwise appropriated, in addition to amounts set forth in said act, $25,000,000, which shall become available for expenditure July 1, 1919, and the sum of $25,000,000, which shall become available for expenditure July 1, 1920, which sums shall be expended along with and in the same manner and under the same provisions as directed in the aforesaid act and as herein amended.

SEC. 23. That not later than the first Monday in December of each year the commission shall make a report to Congress showing the operations and expenditures, under the foregoing provisions of this act, for the preceding fiscal year.

SEC. 24. That this act shall be in force from and after the date of its passage.

Calendar

ENGINEERING

S. A. E. Meetings

Feb. 27—Kansas City. S. A. E. tractor meeting at Sweeney School Auditorium; dinner at Hotel Baltimore.

March 5—Minneapolis Section, S. A. E.—Hotel Radisson. "Tractor Service and Sales."

March 7—New York. S. A. E. Aircraft Meeting at Engineering Societies Bldg.

April 2—Minneapolis Section, S. A. E.—Hotel Radisson. "Implements Designed for Tractor Belt Power and Their Characteristics."

SHOWS

Feb. 22-March 1—Hartford, Conn. Hartford Automobile Dealers' Assn., Inc., Broad Street Armory. Ben F. Smith, Manager.

Feb. 22-March 1—Atlantic City, N. J. Auto Trades Assn. of Atlantic City.

Feb. 22-March 1—New Castle, Pa., Lawrence County Association of Automobile and Accessory Dealers.

Feb. 22-March 1—Reading, Pa. Reading Auto. Trade Assn.

Feb. 23-March 1—Cedar Rapids. Auditorium, Automobile Dealers' Assn.

Feb. 24-March 1—Burlington, Ia. Second Annual.

Feb. 24-March 1—Kansas City, Mo.—Kansas City Motor Dealers' Assn. E. E. Peake, Manager.

Feb. 24-March 1—Springfield, Mass. Automobile Dealers' Assn. Harry W. Stacy, Manager.

Feb. 24-March 1—Springfield, O. Auto. Trade Assn.

Feb. 24-March 1—Portland, Ore. Ninth Annual Dealers' Motor Car Assn., Automobile Palace. M. O. Wilkins, Manager.

Feb. 24-March 1—Duluth, Minn. Duluth Automobile Dealers' Assn.

Feb. 25-March 1—Erie, Pa., United States Garage.

Feb. 26-March 1—Mason City, Ia. Fifth Annual, Mason City Auto Show Assn.

Feb. 26-March 1—Madison, Wis. Seventh Annual, Automobile Dealers' Division of Madison Assn. of Commerce, Union Transfer Bldg.

Feb. 26-March 1—Quincy, Ill. Cars, Quincy Automobile Trade Assn. Armory.

Feb. —Wheeling, W. Va. Automobile Show at Market Auditorium.

March 1-8—York, Pa.

March 1-8—Detroit, Mich. Detroit Automobile Dealers' Assn. H. H. Shuart, Manager.

March 1-15—New York Aeronautical Exhibition, Manufacturers' Aircraft Assn., Madison Square Garden and 69th Regiment Armory.

March — Scranton, Pa. Thirteenth Regiment Armory, Scranton Automobile Assn.

March—Utica, N. Y. Utica Motor Dealers' Assn. W. W. Garabrandt, Manager.

March—Philadelphia, Pa. Philadelphia Automobile Trade Assn. Passenger cars.

March 3-4—Bristol, Conn. First Annual, Bristol Automobile Dealers' Assn., Armory.

March 3-5—Quincy, Ill. Trucks and Tractors. Armory.

March 3-8—Muskegon, Mich. Third Annual, Armory, Muskegon Lodge No. 274, B. P. O. E. John C. Fowler and George M. Friant, Managers.

March 3-8—Dayton, O., N. A. C. A. Building.

March 3-8—Columbus, O. Columbus Automobile Show Co., Memorial Building. W. W. Freeman, Manager.

March 3-8—Raleigh, N. C. Third Annual. H. B. Bolton, Manager.

March 3-8—Scranton, Pa. Ninth Annual, 13th Regiment Armory, Scranton Automobile Assn. Hugh B. Andrews, Manager.

March 3-8—Buffalo, N. Y. Buffalo Automobile Dealers' Assn.

March 3-8—Richmond, Va. Third Annual, Richmond Automobile Trade Assn., Gray's Armory.

March 3-8—Worcester, Mass. Annual Show, Casino Auditorium.

March 5-8—Lancaster, Pa. Automobile Trade Assn., Rowe Motor Co.'s Bldg. R. W. Shreiner, Manager.

March 8-15—New Brunswick, N. J. Armory, New Brunswick Motor Trade Assn. William Kuehle, Manager.

March 8-15—Philadelphia, Pa. Philadelphia Automobile Trade Assn., Commercial Museum. A. L. Maltby, Manager.

March 10-12—Lancaster, Pa. Truck Show.

March 10-15—Paterson, N. J. Paterson Automobile Trade Assn., Fifth Regiment Armory. H. MacGinley, Show Manager.

March 10-15—Salt Lake City, Utah. Sixth Annual, Bonneville Pavilion. W. D. Rishel, Manager.

March 10-15—Syracuse, N. Y. Syracuse Automobile Dealers' Assn. Harry T. Gradner, Manager.

March 10-15—Omaha, Neb. Fourteenth Annual, Omaha Automobile Trade Assn., Auditorium. Clark G. Powell, Manager.

March 12-18—Peoria, Ill. Passenger cars, 12 to 15; trucks, 17 and 18.

March 15-22—Boston, Mass. Boston Automobile Dealers' Assn. Passenger cars only. Chester I. Campbell, Manager.

March 15-22—Harrisburg, Pa. Harrisburg Motor Dealers' Assn., Overland Warehouse. J. Clyde Myton, Manager.

March 17-22—Great Falls, Mont. Montana Automobile Distributors' Assn.

March 17-22—Philadelphia, Pa. Motor Truck Assn., Commercial Museum.

March 19-22—St. Joseph, Mo. St. Joseph Automobile Show Assn., Auditorium. John Albus, Manager.

March 19-22—Norfolk, Neb. Norfolk Automobile Show Assn.

March 19-22—Warren, Pa. Third Annual, Warren Automobile Dealers' Assn.

March 22-29—Pittsburgh Automobile Dealers' Assn. of Pittsburgh. John J. Bell, Manager.

March 22-29—Passenger Cars. April 1-5—Trucks, Brooklyn. Brooklyn Motor Vehicle Dealers' Assn. I. C. Kirkman, Manager.

March 24-29—New Orleans, La. Henry B. Marks, Manager.

March 24-29—Greenfield, Mass. Greenfield Automobile Dealers' Assn., State Armory. James J. Callahan (Pittsfield) Manager.

March 24-29—Utica, N. Y. Utica Motor Dealers' Assn.

March 26-29—Watertown, N. Y. Tenth Annual, State Armory, Automobile Dealers, Inc. Arthur E. Sherwood, Manager.

March 28-30—Peru, Ill. Illinois Valley Auto Show.

Third week March—Trenton, N. J. Trenton Auto Trade Assn. John L. Brock, Manager.

April 5-12—Bridgeton, N. J. Fourth Annual, Automobile Dealers' Assn.

April 5-12—Montreal, Can.—National Motor Show of Eastern Canada, Victoria Rink. T. C. Kirby, Manager.

April 13-19—Bristol, Tenn. Cars, trucks, tractors, airplanes and accessories. Bristol Chamber of Commerce.

April 14-19—Bristol, Va.-Tenn. Cars, Trucks, Tractors. C. W. Roberts, Manager.

Not decided—Bridgeport, Conn. Auspices of City Battalion. B. B. Steiber, Manager.

Not decided—Indianapolis, Ind. Indianapolis Auto Trade Assn. John B. Orman, Manager.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

TRACTOR SHOWS

Feb. 24-March 1—Kansas City, Mo. Fourth Annual Tractor Show. Sweeney Building, Kansas City Tractor Club. Guy H. Hall, Sec.

RACES

March 15—Santa Monica, Cal. Speedway.

March 23—Los Angeles. Ascot Speedway Assn., Ascot Speedway, 150 miles.

May 17—Uniontown, Pa., probably 112½ miles.

May 31—Indianapolis. Indianapolis Motor Speedway Assn., 500 miles.

July 5—Cincinnati, O., Speedway.

July 19—Uniontown, Pa. Speedway race.

July 26—Sheepshead Bay, L. I. Speedway race.

March 7—Automobile Export Managers Convention, N. A. C. C. headquarters, New York.

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago—National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

War Department May Lend Aviation Engines for Educational Work

WASHINGTON, Feb. 24—The Senate has passed an amendment authorizing the loan of aviation engines and aircraft material to educational institutions. Two or three such institutions, including the College of the City of New York, have requested the War Department to lend them Liberty engines for the use of students. The War Department was willing to do this, but has not had the authority. By this amendment the War Department has authority to make such loans at its own discretion, reserving to the Government the title to the motors and all other material.

The text of the resolution reads as follows:

"That the Secretary of War is hereby authorized and empowered, for the purpose of aiding, fostering and promoting educational experimentation work, to loan aircraft motors and aircraft equipment to such educational institutions in the United States as provide advanced mechanical and technical instruction, under such rules and regulations as the Secretary of War may prescribe."

The amendment was agreed to and the joint resolution was reported to the Senate as amended. The amendment was concurred in by the members of the Upper House and passed.

Air Information by the A. A. A.

NEW YORK, Feb. 25—The American Automobile Assn., which has for years made and provided maps for motorists, has now added the production of air maps for flying, and will show at the aeronautical exhibition gigantic maps of the United States with the established air lanes, landing fields and prominent landmarks, together with compass readings. It will also display strip maps adapted to the needs of the aviator. An aero map of Long Island will be seen for the first time. Permission has also been secured to display some of the special Government aerial maps which the organization helped to prepare.

CONTINENTAL MOTORS · AMERICA'S STANDARD

Powerful as the Nation

The Red Seal Continental Motor Appeals to Every Member of the Family

To those who consider the purchase of an automobile the motor is invariably the central point of interest.

Literally, the motor makes the motor-car. Almost all the main qualities of a car—its power, its speed, its silence, its reliability, its flexibility—are elements of the motor.

These essential qualities are assured in advance to those who buy Continental-powered cars. For behind each Red Seal Continental Motor stand hundreds of thousands of other Continental Motors, each of which has proved itself worthy of the Red Seal of character. Standing, as it were, at the side of every prospective purchaser of a Continental-powered car are hundreds of thousands of owners, who say:

"Take our advice. Buy the car with the Red Seal Continental Motor. Then you'll be *sure* of 100% motor value."

Lyons Fair Discloses New Post-War Models

About One-Third of French Makers Have Entirely New Products—Remainder Have Pre-War Products—Electric Starting and Lighting Universal

TENDENCY TOWARD STANDARDIZATION PLAINLY APPARENT

Block Cylinders, Detachable Heads and Other Modern American Characteristics Come to the Front

By W. F. Bradley
AUTOMOTIVE INDUSTRIES' *European Correspondent*

LYONS, FRANCE, March 2—*Special Cable*—Europe's first great exhibition of post-war models—the Lyons Fair—was thrown open today and holds a record number of exhibits with those of automobile manufacturers grouped prominently together in one big hall. All told there are 90 separate automobile exhibits and though it was hardly to be expected that the fair would disclose a great deal that is new in the way of post-war models, it has, nevertheless done so.

Trend Toward Standardization

Perhaps the most striking feature of the automotive exhibits as a whole is the marked trend toward greater standardization and the use of engineering practices which long have been features of American products. This applies particularly to the universal use of electric lighting and starting equipment, the use of block cylinders with detachable heads and the fitting of practically all low and moderate price cars not only with bodies but with all other equipment as well.

As the Lyons Fair not only takes the place of that of Leipsic, but aims to surpass it in every sense, it is of interest to note that the number of exhibitors passes all previous records, the actual number being 4,700. Naturally, the French exhibitors predominate with a total of 2,994, but the United States makes a very creditable showing with a total of 618.

Few Foreign Cars Exhibited

Apart from the general interest surrounding the first after-war efforts of manufacturers to display their products on a really large scale, the fair holds much of interest for the American manufacturer of automotive products. It is true that automotive exhibits are relatively few, but the interest is still there. In all, there are six exhibits of cars of European make other than those of French manufacture. This small total is doubtless due to the fact

Pronounced Engineering Tendencies at Lyons Fair

1—*Increasing use of cantilever springs.*

2—*Two-unit lighting-starting systems.*

3—*Adoption of detachable cylinder heads.*

4—*Unit construction of engine and gearbox.*

5—*Spiral bevel final drive.*

6—*Detachable wheels with clincher rims.*

7—*Transverse pump and magneto shafts.*

8—*High class cars, six-cylinder.*

9—*Only one eight, no twelves.*

10—*Low-priced cars all fours.*

that at the present time the importation of automobiles to France is prohibited owing to causes relating to internal commercial economics. So far, there is but one American car, the Columbia, actually on exhibition, but it is anticipated that there may be others represented before the fair is in full swing.

About one-third of the French exhibitors are showing entirely new models, the remainder exhibiting pre-war cars with the addition of electric lighting and starting equipment. It is significant that no car shown is minus a complete electrical system, in view of the fact that hitherto starting and lighting, as looked upon in America as forming part of the regular equipment of a passenger car, has been either absent or in some few cases has been installed as an extra at additional cost.

Cantilever Springs Featured

Dominating tendencies, as applied to general production, have been conspicuous by their absence in European engineering practice in the past. Each factory has, rather, relied on its engineer's expression of individuality in its product. It is a sign of a new order of things that there is now a decided tendency to the use of cantilever springs, detachable cylinder heads, two-unit starting and lighting systems and spiral bevel final drive. Power plants, where the engine, clutch and gearset combine to form a unit, are another feature which is much in evidence and which evinces a trend toward American practice.

Detachable Steel Wheels

Magneto ignition is practically universal, a condition which is far different from that obtaining in the United States. Detachable wheels with permanent rims of clincher type are popular; in fact, the clincher type of tire attachment fully maintains its popularity. There is considerable use of detachable steel wheels, usually of Michelin make.

Individually designed bodies have always been a point with the European manufacturer and the fair discloses that sombre colors predominate. Detachable upholstery is featured and a departure from pre-war practice is indicated by the fact that all the lower-priced cars now are offered complete with all accessories.

No Twelves; Only One Eight

In the higher-priced grades engines having six cylinders predominate practically to the exclusion of all others; there are no twelves and the only eight-cylinder is the De Dion Bouton, a model which has been on the market for some years. The announcement has been made that the Lorraine-Dietrich company will build a twelve and also two six-cylinder models.

The Delage, known in the United States through its success as a racing machine, has a striking exhibit of a six-cylinder model with block-cast engine and bore and stroke of 80 x 150 mm. This engine is designed to develop 70 hp. and is fitted with a starting motor operating through a Bendix drive. Brakes are fitted on all four wheels, operating on 15-in. drums and designed to stop the car in 100 yd. or less at 60 m.p.h. High-class work and refinement of detail are in evidence throughout this car, which sells in France for approximately $5,700. This car is equipped with wire wheels.

Few New Manufacturers

But few new firms have entered the automotive industry, doubtless owing to the limitations placed on private enterprise by the universal need for the production of war munitions. An exception is that of the Voisin Aeroplane Co., which is building a car powered with a 40-hp. Knight engine. The Citroen Co. is building a light four-cylinder machine and the Swiss Picard-Pictet Co. is now backed by the manufacturers of the well-known Gnome rotary airplane engine.

Mayen, the biggest aviation engine builder in

France, is producing Hispano-Suiza cars under license and it may be said that the three most prominent European builders to-day are Peugeot, Fiat and Citroen. Much attention is being given to the production of light four-cylinder cars and it is in this connection that these three concerns are mentioned. The light-weight Fiat comes out at 1400 lb., the Peugeot at 1350 lb., and the Citroen is the same weight as the Fiat.

Left Steering, Center Control

Although the Fiat is considered to be a popular model, in a relative sense, it is of especially high-class construction. Cylinders are block-cast and have a bore and stroke of 65 x 110 mm., heads are detachable, the crankshaft has three bearings, the power plant is a unit and lighting and starting are included as regular equipment. Final drive is spiral bevel, the wheels have detachable steel spokes and the rear axle is of full-floating type.

A new Peugeot is, in effect, an enlargement of the well-known Baby Peugeot of former years. Bore and stroke are 60 x 100 mm. and the crankcase is a single casting, the only example in the fair. This car has left-hand steering—unique in European practice—and center control. Detachable wood wheels are fitted and the springs are of cantilever type.

Frame Construction Changing

The new Citroen has a block-cast engine of 65 x 100 mm. bore and stroke with detachable cylinder heads. Here, again, is left-side steering featured in conjunction with center control. The crankshaft has two bearings, final drive is through Citroen herringbone gears and the rear springs are single quarter-elliptics. Double quarter-elliptic front springs are fitted, one above and the other below the axle. The price of the two-seater is approximately $1,450. In this class car the usual frame construction embodies three cross-members, power plants being carried on three-point suspension.

This three cross-member feature is also incorporated in higher grade cars, but in these the engine is carried on four points in order to stiffen the frame. Front crankcase webs are carried out, avoiding the use of underpans and a material increase in the depth of the frame side-members is evident.

Five Makers Produce Tractors

Panhard and Levassor are producing both Knight and poppet valve models, but, except in the case of the Voisin company, there is no extended use of the Knight type of engine. There are no new valveless engines.

Automobile firms which are engaged in the production of farm tractors are Peugeot, Fiat, Paris Omnibus Co., Schneider and Latil, but it is reported that the Renault and Panhard companies are also building tractors, although they do not exhibit them. The Fiat tractor is built generally along the lines of the Fordson, but is larger and heavier, using a 4-ton truck engine.

The Peugeot tractor is of track-laying type with a modified truck engine and the Paris Omnibus Co.'s machine is built under the British Saunderson license. Trailers for commercial service occupy an important position at the fair for the first time, their importance as shown in war-service having led the firms producing them to develop them for use under normal conditions. They are exhibited in two and four-wheel types and invariably have rubber tires.

Lowest Priced Car Costs $950

The lowest priced car at the fair is exhibited by the Lyons Aviation Co. It is a four-seater with electric lighting and starting, two-cylinder, two-cycle engine with a bore and stroke of 75 x 120 mm. and a wheelbase of 123 in. The body is of enameled sheet steel, the four seats are adjustable and the weight is 1300 lb. Present price is approximately $950, but it is stated that if 10,000 cars are sold by the end of March the price will be reduced by about $40.

Announcement was made to-day that an automobile show would be held in Paris next fall, but the actual date is not yet determined, nor has it been decided where it will be held.

Trends in European Body Design

1—*Increasing use of detachable upholstery.*

2—*Sombre color schemes the rule.*

3—*Cheaper cars completely equipped.*

4—*Left steering, center control increases.*

5—*Many detachable steel wheels.*

6—*New fours light in weight.*

Element of Practical Business at Aeronautical Exposition

Few Commercial Adaptations But Plenty of Promise—Extensive Army and Navy Exhibits

NEW YORK, March 1—The first aeronautical exhibition since the war ended, which opened here to-night in Madison Square Garden and the 69th Regiment Armory, under the auspices of the Manufacturers' Aircraft Assn., is notable from at least three points of view:

1—It demonstrated by the huge crowds it attracted the tremendous public interest in the latest means of rapid transport;

2—It provided fruitful opportunities for students of modern aerial warfare, amateur and professional, to become acquainted with the very latest developments of both military and commercial machines;

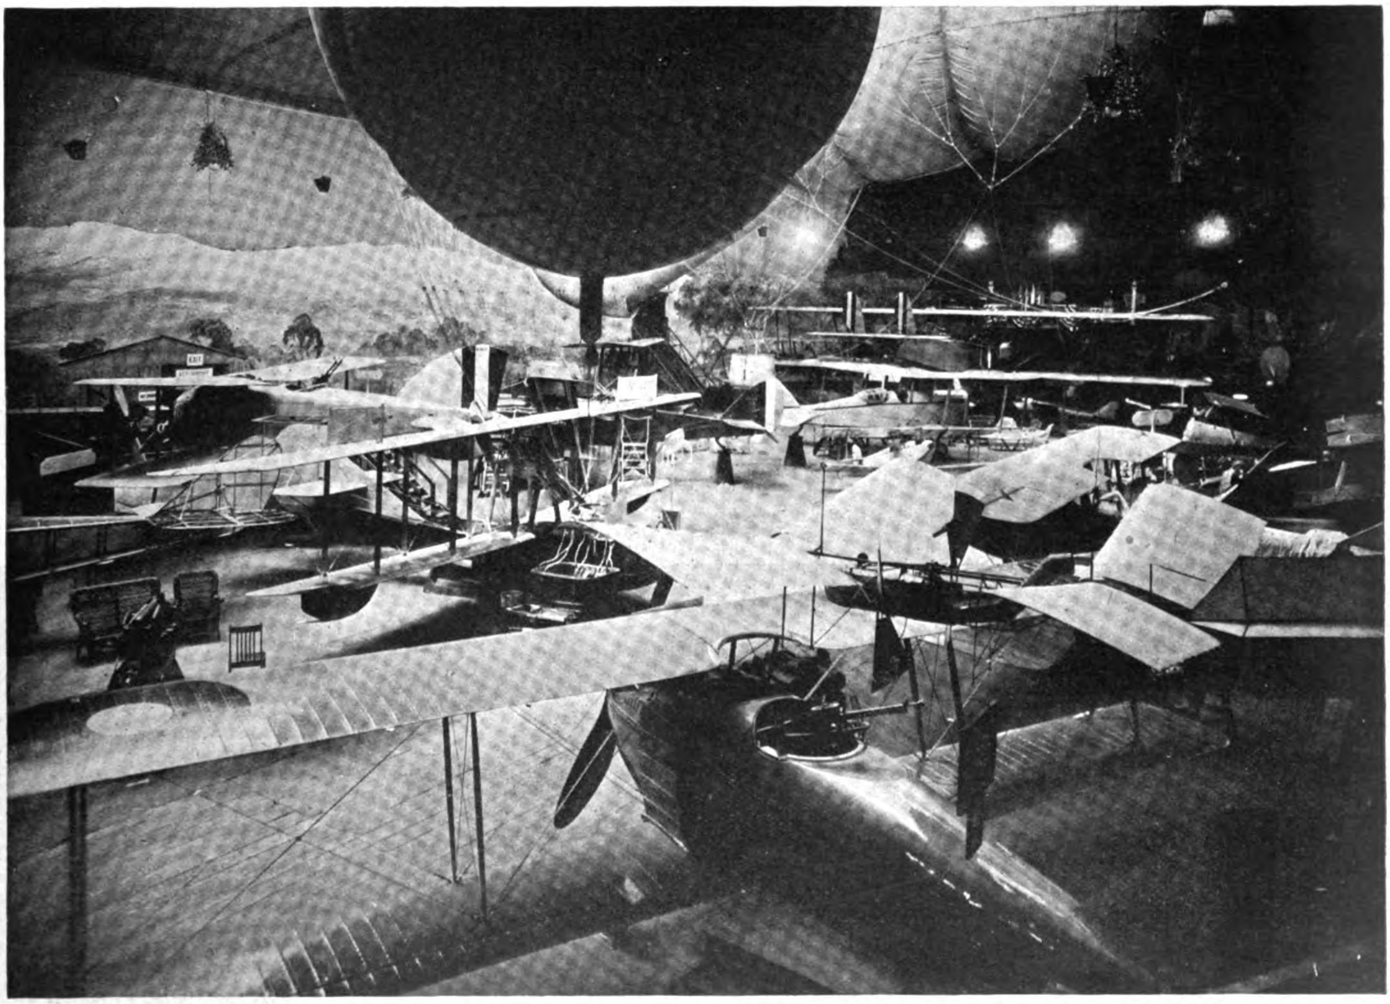
3—And, perhaps most important of all, it sounded an unmistakeable keynote of energy and optimism on the part of the aeronautical industry.

The present show differs from all previous shows, both in this country and in Europe of pre-war days, in the introduction of the element of practical business.

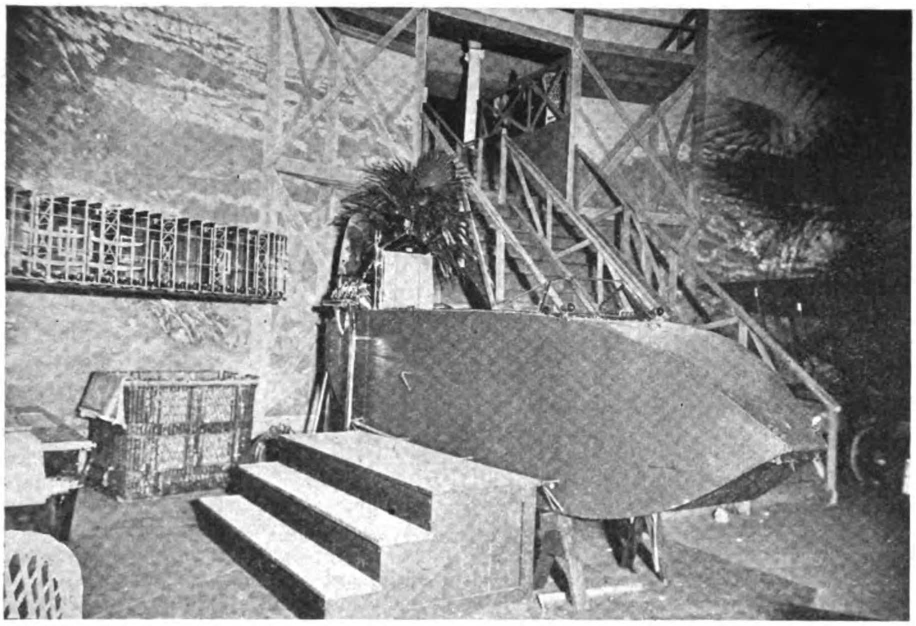
Although the exhibits are dominated by aircraft built solely for war purposes, there is easily recognizable in the spirit of the show the determination of the industry to switch over a large share of its energy to civil aeronautics.

It is true that there are no special dump bodies or attachments for the carrying of merchandise on exhibition but not much imagination is required to transform the bomb-carrying devices of the larger planes and air-boats into equipment for peaceful purposes.

The big Caproni triplane, which spans one end of the Armory, has a large structure under the lowest wing that carries 3300 lb. of bombs. And many of the smaller planes, seating one or two passengers, carry three or four guns, an appreciable weight that would be made available for freight in the commercial airplane.



General view of the aeronautical exhibits in Madison Square Garden. Suspended at the right is the steam-driven plane designed and flown by the pioneer Langley twenty-three years ago



A corner of the Goodyear company's exhibit, showing a dirigible car equipped with a Curtiss 100-hp. engine designed for 28 hr. continuous flight with four men aboard. To the left is a scale model in skeleton of the car for a proposed 1,000,000-cu. ft. dirigible to carry twenty-four passengers

But in spite of the probable early demand for commercial load-carrying aircraft, the feeling seems to be general among the manufacturers who have specialized on the smaller military machines that the readiest means of establishing themselves on a sound basis lies in the appeal to the sportsmen of the country first and afterward to the larger business of passenger and freight carriers.

Having developed machines that are satisfactory for military or training purposes, they intend to continue turning them out with as little change as possible for a class of user who is likely to make the quickest response. There can be no doubt that the sportsman aviator already exists in appreciable numbers, and the manufacturers have started out to meet him in the New York show by displaying a number of single and two-seated planes and flying boats with a strong sporting appeal.

Enter the Sport Plane

Typical of these machines is the Packard, which seats two in tandem; the Curtiss MF two-seated flying boat, in which the passengers sit side by side; the L. W. F. hydro airplane; the Messen-

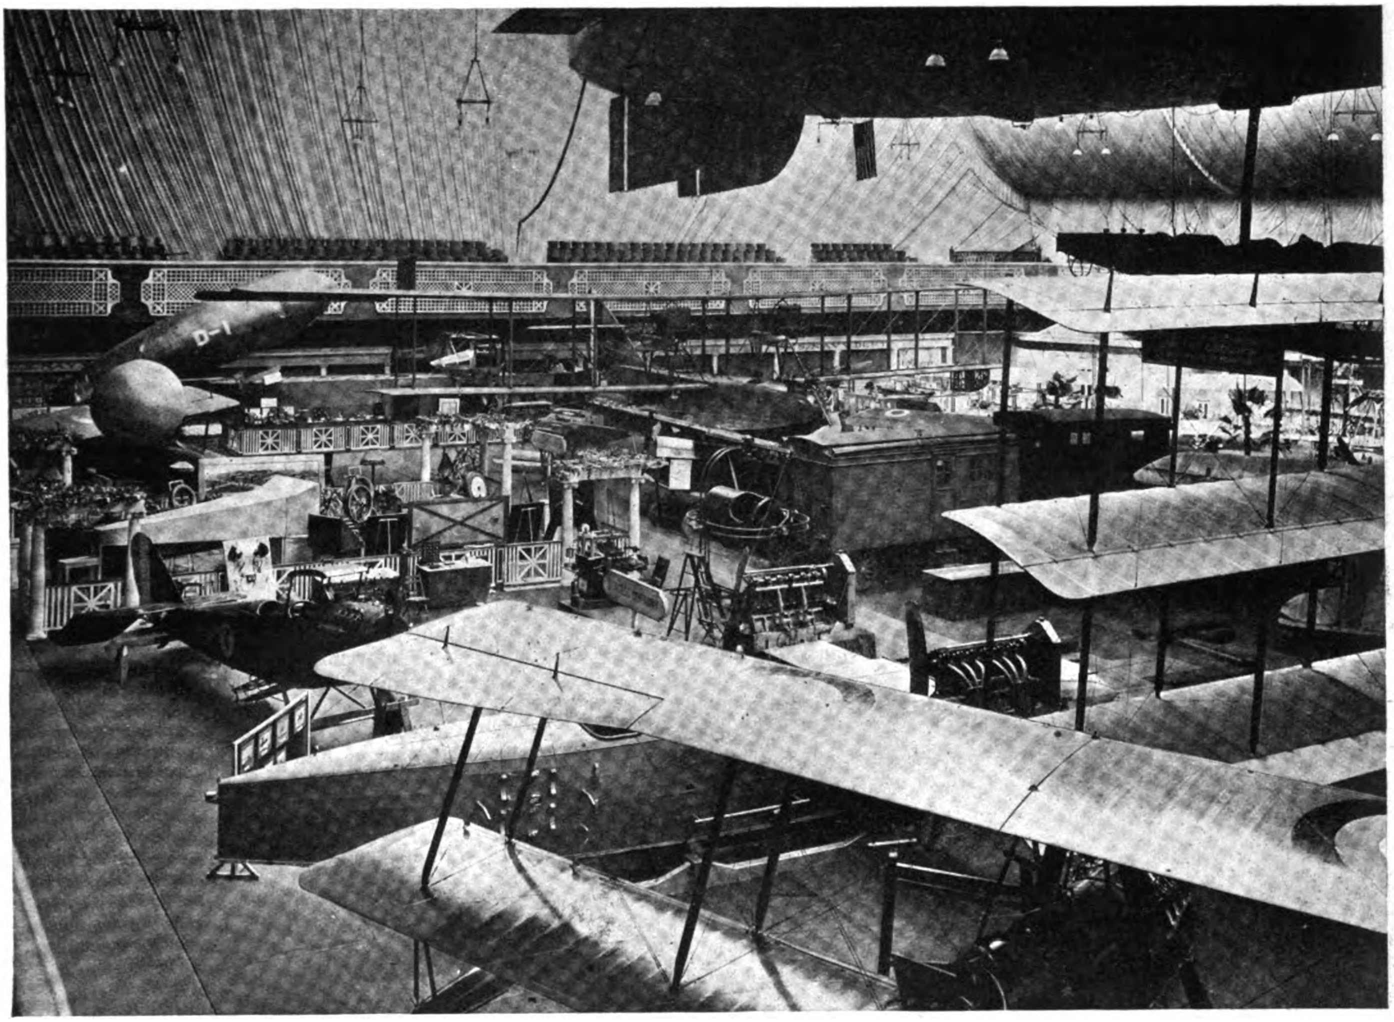
The new Aeromarine six-cylinder 125-hp. aero engine



General view of the 69th Regiment Armory section of the New York show, showing overhead the Navy Coast Patrol dirigible which has seen 17 months' service for the Government. In the background is the big F-5-L Navy flying boat

ger of the Dayton-Wright Co., a tiny one-seater biplane with a span of only 19 ft., and the flying boat of the Aeromarine Co., which seats two passengers under a celluloid top in addition to the pilot.

The features that will differentiate civil from military craft have not had time to develop since the signing of the armistice, but there is ample evidence that the industry is hard at work on these problems.

Several planes at this show boast of refinements that indicate this tendency. Windowed cowls that protect the occupants from the elements, superior body finish, ease of mounting, luxurious comfort of upholstery, beauty of body lines and color strongly resembling and obviously borrowed from the best motor car body practice are a few of these that strike the eye of the visitor. That more of these features were not in evidence is due solely to the fact that there had not been time to develop them. Most of the makers of military craft are anxious to continue production of proven models with only those changes that are necessary to turn them into everyday airplanes for civil use, mail and parcel carrying and sporting types.

That there is a prospective market for the really small machine, a sort of motorcycle of the air, is suggested by the appearance of a tiny monoplane with floats, called the Loening Kitten, almost hidden under the shadow of the Navy F-5-L flying boat in the Armory, and one or two others scarcely any larger.

The Kitten has a wingspread of only 18 ft. and is equipped with an air-cooled Lawrence engine of 60 hp. It is a practical-looking machine with characteristics resembling the well-known Loening accepted by the Government for fast military work.

Another small plane with radical departures from standard construction is shown by the Gallaudet Aircraft Corp. The power plant consists of two Indian motorcycle engines connected through clutches and bevels to a pair of propellers on each side of the fuselage behind the

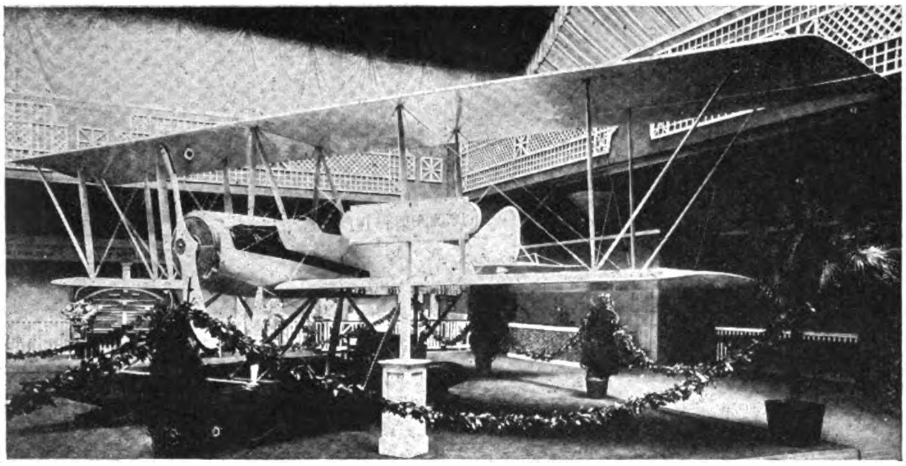
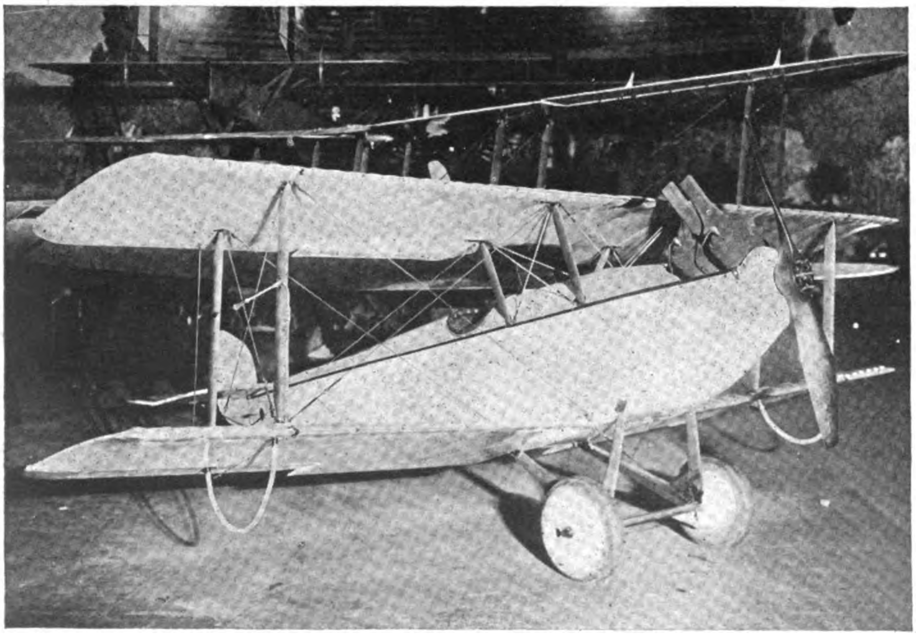
The three-passenger flying boat of the Aeromarine Plane & Motor Co.



The sporting model hydro-airplane brought out by the L. W. F. Co. is equipped with a 120-hp. Sturtevant



The Dayton-Wright company's single-seater "Messenger" has a span of only 19 *ft.*

wings. The Dayton-Wright Messenger, already mentioned, is also equipped with an air-cooled engine, of 37 hp. There seems to be a desire to try out the possibilities of air cooling to avoid the weight and complication of radiators and connections.

The Curtiss flying boat is fitted with a Spanish cedar hull that glows with the polish and finish of the high-priced automobile. The upper wing has a span of 49 ft. 9 in. and the lower 38 ft. 7 in. The landing speed is 45 m.p.h. and the maximum is 70 m.p.h. It is equipped with a Curtiss 100-hp. eight-cylinder engine with a bore and stroke of 4¼ in. and 5¼ in.

The so-called Honeymoon Express shown by the Dayton-Wright Co. is suggestive of the refinements that are to come. It seats two passengers in a comfortable canopied compartment with the pilot's seat in front. The interior is upholstered and fitted with vanity and lunch boxes and even a mirror. Its cost ranges from $15,000 to $20,000. The motive power is a Liberty 12.

A sporting plane has been brought out by the Thomas Morse Aircraft Corp. with tandem seating for two, a landing speed of 38 m.p.h. and a flying maximum of over a hundred miles an hour. Another model, the S-7, has a side-by-side seating arrangement. Its maximum is 90 m.p.h. Both models use 80-hp. Le-Rhone radial engines.

Constructional Development

Of construction interest there is much to be seen. Several machines have streamline noses, with the radiator mounted in the wing. There is a noticeable tendency to more rugged construction throughout, in landing gear strut work and engine mounting. Already salesmen have discovered selling points and these are exhibited in the same way that automobiles are sold. On the Packard sliding doors on the side of the engine casing give access to the carbureter and the crankcase.

A model showing the progressive stages in the making of the monocoque fuselages for the L. W. F. planes is shown. This body has given entire satisfaction with regard to strength and streamline possibilities. It is made of successive layers of linen and wood set spirally over a former which collapses when the work is finished.

This company exhibits two marine models, one, the G-o, carrying seven machine guns and bomb-dropping devices. With these removed there would be ample provision for the carrying of mails or parcels. It is equipped with a Liberty engine and sells for about $15,000. An L. W. F. sport hydroairplane is also shown. This model has a wing spread of 46 ft. and has two pontoons 18 ft. long. It seats two, is driven by a Sturtevant 120-hp. engine fitte dwith a starting motor and has a flying speed of 80 m.p.h.

Among the engineering exhibits is the Sturtevant company's solution of the problem of maintaining full power at high altitudes by feeding the carbureter automatically with air at a constant pressure. The device consists of an air pump driven by a belt from the crankshaft at

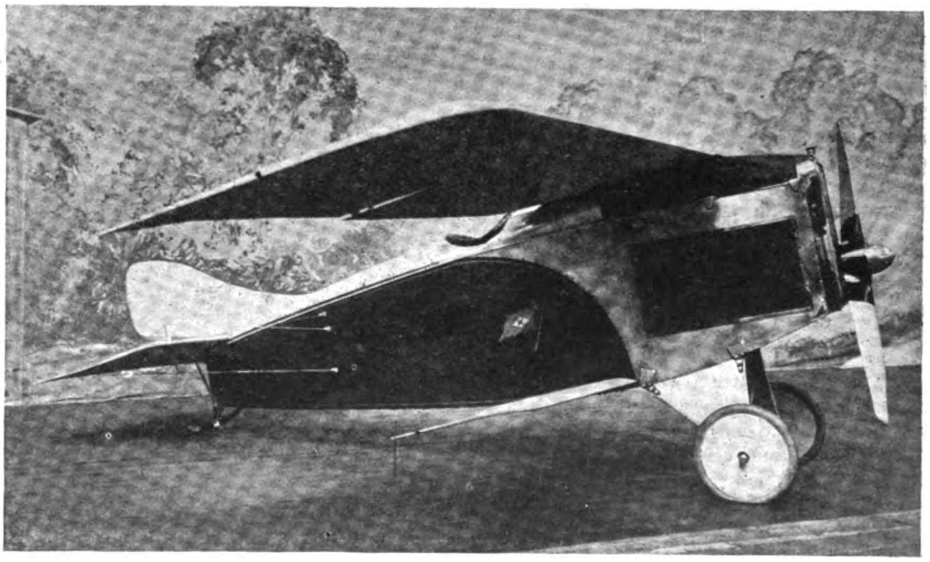
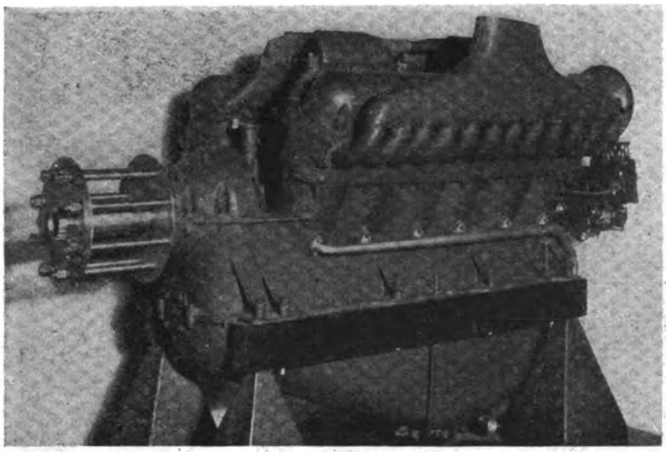
The Navy Coast Patrol dirigible built by the Goodrich company occupied most of the sky space in the Armory. This ship has covered 23,000 miles in Government service. It is 167 ft. long, has a volume of 80,000 cu. ft. and is driven by a 100-hp. engine

Curtiss model 18-B biplane, said to be capable of 170 m.p.h. The fuselage is similar to that used in the Curtiss K triplane



The Christmas "Bullet" has no exterior supports for the wings



The Curtiss 375-hp. twelve-cylinder aero engine has its cylinders set at a 45-deg. V. The bore and stroke are 4½ in. by 6 in. It weighs 680 lb.

a speed varied according to the altitude by an air controller. This controller is a small cylinder and spring supported piston open to the atmosphere. The position of the piston controls the tension of the belt. It is said to consume about 0.6 of the engine horsepower which represents a considerable increase on the available horsepower of an engine with the carbureter air inlet open to the atmosphere, at high altitudes.

The Navy exhibits, shown in an accompanying table, are of great interest. The big F-5-L flying boat is exhibited with one half of body and wing completely stripped, exposing the construction, the bomb release mechanisms, instruments, controls, gasoline tanks, guns, ammunition racks, etc. This machine is of the type which has done so much work in convoying transports and merchant ships. It carries a crew of five men and ammunition and bombs for 8 hr. at a speed of 80 m.p.h. The total weight, fully equipped, is almost 14,000 lb. Other Navy exhibits are the various instruments, clocks, compasses, barometers, etc., used in aviation work. A small model of a dirigible filled with helium, the new non-inflammable gas with a buoyancy only slightly less than hydrogen, is also shown.

Of Lighter-Than-Air Interest

The lighter-than-air side of the industry is well represented, and there is evidence of the same optimism and planning for the future. The Goodyear company is showing an army fuselage for dirigibles, equipped with a 100 hp. Curtiss engine, designed for 28 hours continuous flight with four men aboard. This company also shows a scale model for a passenger car for a proposed dirigible with a cruising radius of 5000 miles without landing. This ship will be 450 ft. long. The car is 50 ft. x 7 ft. and has accommodation for twenty-four passengers.

From the decorative point of view the exhibition surpasses anything hitherto staged in these buildings. The always difficult problem of combining conventional design with naturalistic treatment has been avoided by leaving out the conventional geometric pattern entirely. The entire wall surface of the Garden is a vast scenic painting representing rocky country, with great distances and a sky which meets the blue gauze which covers the entire roof. The whole effect is magnificently spacious and particularly appropriate to the nature of the exhibits.

"Farm Mechanics" a New Trade

WASHINGTON, March 3—The extensive use of motor trucks, farm tractors, passenger cars and lighting and power systems on farms will soon create a demand for specially skilled "farm mechanics" on farms of 100 acres or more, according to the opinion of the Federal Board for Vocational Training. These "farm mechanics" it is expected will operate and repair all farm machinery operated by gasoline engines.

Worthy Merchandising Features at Kansas City Tractor Show

Cutaway Chassis—Better Painting and Well Arranged Booths

By David Beecroft

KANSAS CITY, MO., March 1—More attention to the merchandising of tractors was shown by the manufacturers at the Fourth National Tractor Show this year than at any previous show, and if the spirit that was evidenced here is carried on as it should be, it augurs well for a high standard in the future.

Several exhibits are deserving of special mention. They were good in themselves and their influence on the show was splendid. They expressed a new thought in tractor expositions. They possessed a practical appeal.

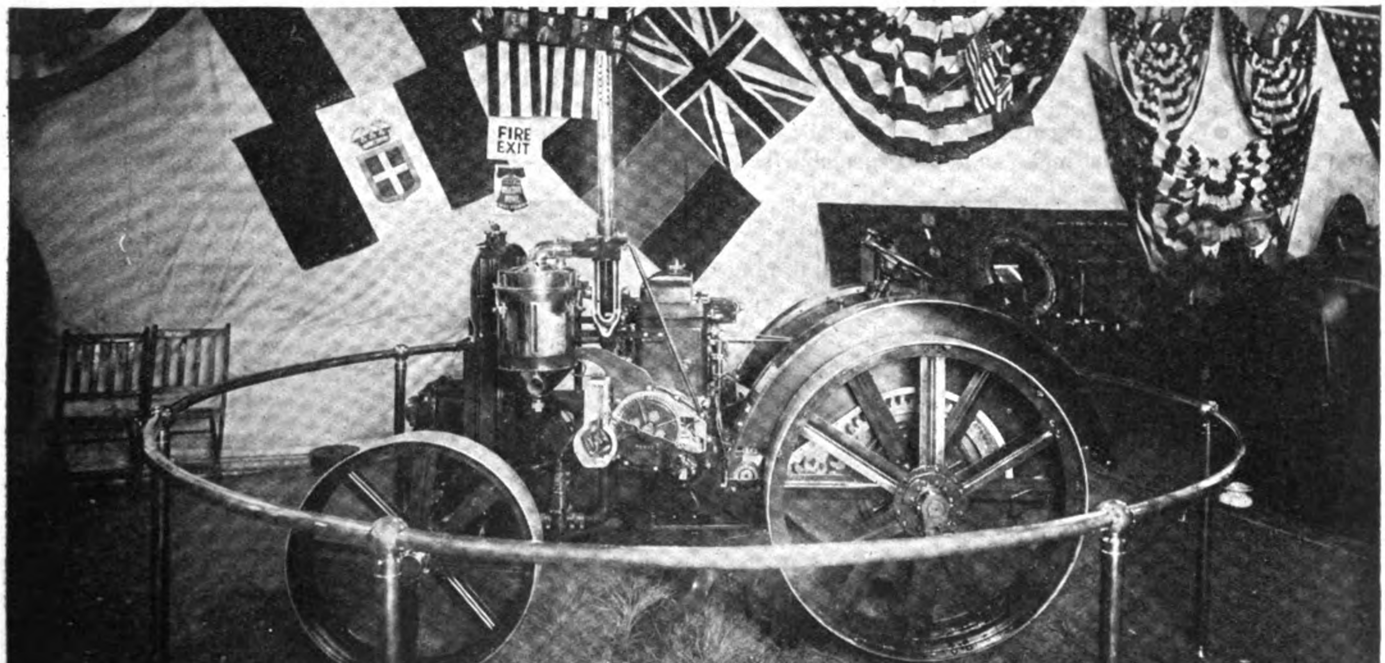
A word of merit goes to the Bates exhibit, which, while unusually attractive, was entirely suitable for the show and carried with it an appeal that must have carried home the new thought of what a revolution the tractor is to work on the farm. It constituted an appealing, well-written chapter on motorized farming. The photographic reproduction tells most of the story.

For a total expenditure of scarcely $300, a plain area of unpainted floor space was converted into a few acres literally extracted from the country. There stood the Bates steel mule in white hitched to a plow in the same color and both in their native element. By means of a platform, a few bushels of good black soil and a few square yards of real grass that grew greener as the show progressed, it was possible to build up a landscape for which a colored farm scene made a fitting background and completed a typical agricultural landscape of the kind we hope to see in all of our forty-eight states within the next decade. The plows were deep in the furrows. You could scarcely tell where the platform stopped and the painting started.

But this was only a part of the exhibit. To the left of this was a raised platform on which the Bates tractor traveled to and fro from the opening of the show until it closed each day. An electric motor and an automatically controlled switch did the job. It was a fine example of motion in an exhibit.

Clever Cutaway Chassis

To the J. I. Case T. M. Co. goes the credit of staging the first high-class cutaway chassis display ever seen at a tractor show in America. One of the two-plow models finished in gun metal with cutaway sections painted in red and white was mounted on a heavy metal pedestal on which it was slowly revolved by an electric motor. There was another electric motor that propelled the mechanism



The Case tractor with cutaway parts was the finest exhibit of its kind ever seen at a tractor show. The finish on the chassis was as good as any on any automobile chassis at an automobile show

of the chassis so that as it revolved on the pedestal the observer had an opportunity of seeing every portion of it working.

As a cutaway chassis it deserves the highest praise, and as an effort to bring class into the tractor industry and impress on every one that the tractor is a beautifully designed, well-finished engineering job, the work could scarcely have been done better. The castings were cut away to show practically every bearing used in the gear-set, transmission system and axles. Never did a motor car chassis go to a New York or Chicago show better worked out to carry its merchandising message.

Surrounding the exhibit with a brass rail permitted many to examine the chassis from all sides with equal ease and satisfaction. It is impossible to think of a better way to disclose good workmanship and design; and where a maker puts these assets into his product he is losing possibilities if he does not follow some such scheme as this to carry the message into the hearts of prospects. We do not know what this exhibit cost, but as a factor in elevating the standard of tractor exhibitions and as a means of silently telling to farmers and dealers the status of tractor design it is unparalleled.

The Value of Color

A new thought in tractor merchandising was expressed by J. B. Bartholomew of the Avery Co., who had the complete line of Avery tractors and cultivators painted white, with gold striping. It represented a great improvement over the implement red that is too frequently seen on tractors. This Avery act recalls a story told by C. F. Kettering, inventor of the many Delco systems, including Delco light. Kettering had an investigation made before putting out Delco light to discover the color of paint most used on farm implements and most asked for by farmers. The majority favored red. That settled it with Kettering. He would paint his Delco light apparatus any other color but red. It simply must not be red.

Here is why: The Delco apparatus was the highest class piece of apparatus Kettering could build and he decided that if it ever went onto the farm painted implement red it would be treated just as any other bit of farm machinery painted red.

It must not go on the farm as such. It must go as a high class job and it must make an appeal as such. There is a strong silent message in the color a machine is painted and if the Delco light was to be cared for as it should and respected as it should then such a continual command should come from the apparatus because of its color. At least color should not be a handicap.

There is an application of this in the color of tractors. The tractor must not fall into the farm machinery class so far as being cared for on the farm is concerned. It is too expensive a product for that. It must carry an appeal for special care. It must carry an appeal that it is a well-designed, well-built, costly yet efficient piece of machinery. The color it is painted will help immensely.

The Avery white line, as it was called at the show, carried a message. There was a good thought back of it, and while tractors would not be serviceable to go into the field in white and gold, the show is a good place to remind the farmer of the value of the machine. The use of white and gold was not limited to Avery, as the American Bosch had a fine exhibit with the center piece in this color, and Bates used it to advantage in his landscape exhibit.

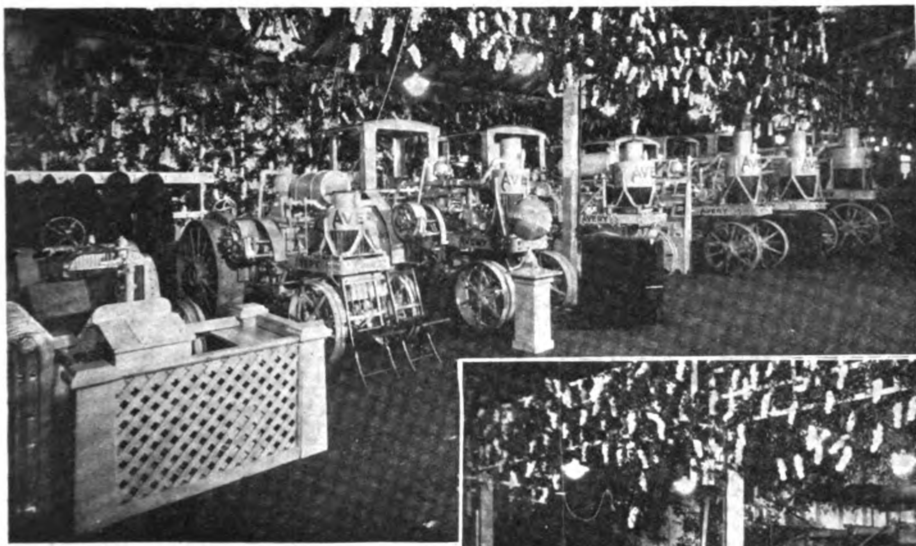
The American Bosch center piece was a Fordson tractor placed on a dais to exhibit its magneto attachment for the tractor. The magneto as well as the gear-case housing the driving gears was in gold. It was the only gold on the chassis and as you passed along the aisle it did not require the services of a salesman to tell you the purpose of the exhibit and explain why a Fordson was in this magneto booth.

Clever Merchandising-Advertising Stunts

Another excellent bit of American Bosch merchandising was a series of large sized photographs telling in sequence every step you had to take in removing the Fordson timer and mounting the magneto system in its place. The pictures told a better story than any salesman could. They were mounted on a large revolving rack adjacent to the front end of the Fordson.

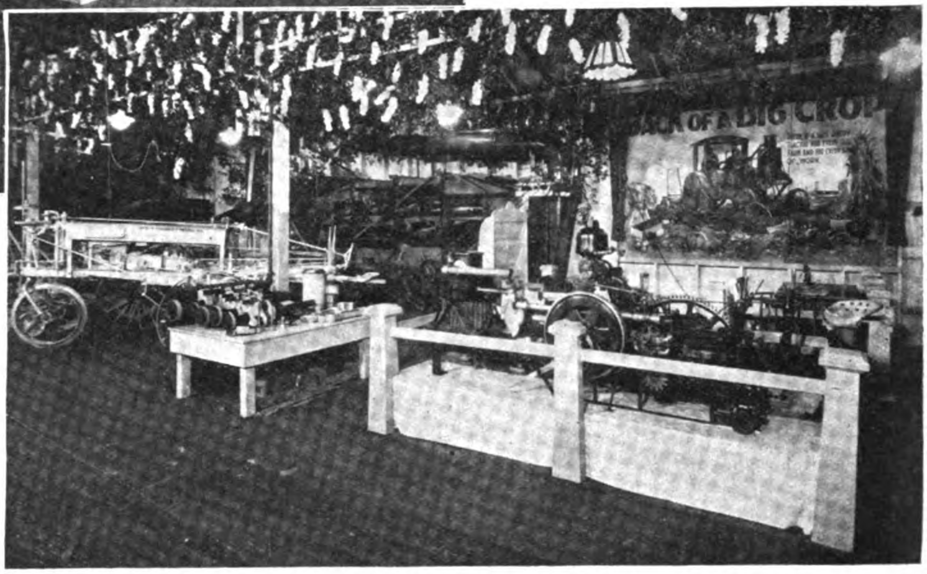
Hyatt took advantage of the show in a merchandising sense; perhaps it would be fairer to say in an advertising sense. This took the form of a goodly sized brown paper portfolio which was for carrying catalogs. So general was its distribution that everybody carried one under his or her arm and the usual littering of the floor with catalogs was not noticed. Hyatt did a good service to the show by this clever scheme and also did a service to every

The center of the American Bosch Magneto stand contained a Fordson tractor painted white, with the Bosch magneto in gold, showing all attachment parts



Manufacturers' Merchandising at the Tractor Show

The long line of Avery models was all painted white with gold stripes, a scheme of uniformity not employed by anyone else, and a pleasant change from red so often used



other exhibitor by insuring more catalogs being carried to the thousands of homes represented at the show. It was fitting that such a pioneer in the tractor field should come out with such a generously useful feature.

Credit is due Strom bearings for a clever display of all bearing types and sizes on a large polished wood pyramid. It stood so high that some exhibitors thought it was too conspicuous and lodged a complaint with the show management, but it was permitted to remain. Exhibits of this character add materially to the interest of a show. The exhibit was a duplicate of one which is now being used at the great Lyons trade fair at Lyons, France.

The use of an automatic steering device for the Cleveland tractor was well shown by having the tractor mounted on what was intended to be a plowed field, with the entire steering mechanism carrying a polished finish and the wheels of the steering apparatus resting in a real furrow of earth. It caused everyone to pause, take a look, grasp the story and generally make some favorable comment before passing.

Never before at a tractor show has there been such an effort to make exhibits pleasing to the eye, attractive and also useful from an educational and merchandising point of view. The show has taken a place in the front rank of exhibition merchandising in this respect. Timken had, for example, one of the yokes which carries the creeper of a Cleveland creeper to show how its bearings are used to carry the idlers as well as the sprockets.

The Cleveland company had a similar yoke exhibit to show the improvements that have been made in the sprockets and other parts.

Rock Island had a moving exhibit of its Heider tractor in the form of a back and forward movement of it.

Most of the tractor concerns had their machines driven by electric motors.

There was a lack of uniformity in size of cards giving information about the tractors, such as rating, weight, price, and a few other essentials. These cards should not necessarily all be the same color but they should be standardized in information given and size.

There is opportunity to make the exhibits of parts such as engines, ignition apparatus, sheet metal goods, bearing materials, castings and other tractor parts more interesting than merely spreading them on the top of a burlap-covered table. That may be the easiest way to exhibit them, but it is far from being the most potential way. Endeavor to put some thought into your exhibit. If you only want it to look pretty without regard to the useful, go ahead and do the best you can. If you want to tell an engineering story think out means of doing it. It may be your mission to incorporate a merchandising story in your exhibit; if so, think out an unusual plan.

Start now planning your exhibit for the fifth tractor show next year. Decide on what message you wish to convey. Make the planning of the exhibit a subject for two, three or perhaps more conferences of factory heads that are interested in the product. Start early.

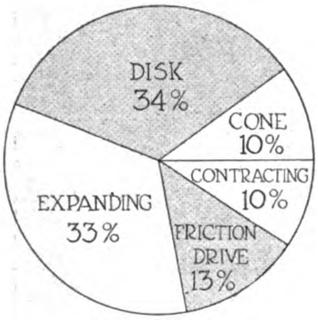
Do your part to elevate the merchandising of tractors and their equipment.

IT is the general view among steel men that the application of the electric furnace in steel refining and steel melting is limited by the cost of electric power. This subject was dealt with in a recent paper by H. Etchells before the Birmingham Metallurgical Society, who said that when electric power was generated with 30 per cent efficiency at the generating station electric furnaces would compete as regards fuel cost with other types. The success of the electric steel-making furnace was due to the utilization of scrap materials hitherto of little value; the production of a class of steel with slightly improved physical properties and of much greater reliability, and easy manipulation and facilities for installing small or large units, as desired.

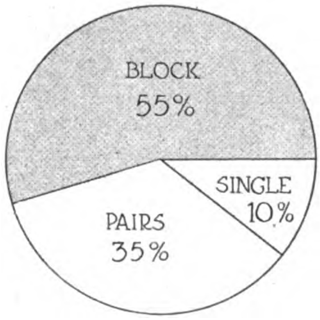
An Analysis of Tractor Specifications

Showing Representation of Different Features of Design on a Percentage Basis—Engine Weight Per Belt Horsepower and Per Cubic Inch Displacement—Average Tractor Weight

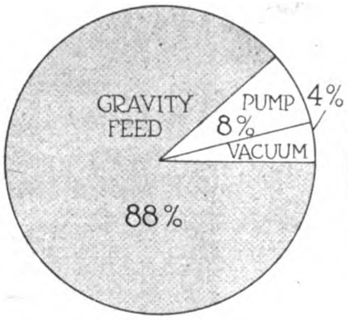
By P. M. Heldt



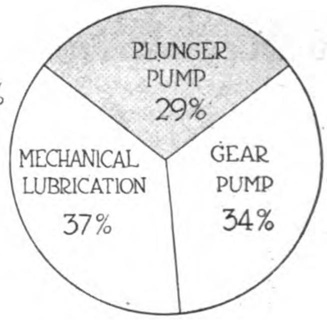
Clutch Types



Cylinder Construction



Fuel Supply



Lubrication

Charts showing the percentage of various constructional features of American tractors

FOR years it has been the custom of AUTOMOTIVE INDUSTRIES to analyze the specifications of automobiles gathered annually on the occasion of the New York Show. The figures thus obtained, showing the prevalence of various practices in percentages, furnish a valuable guide in later years with regard to tendencies in design. In fact, they are about the only basis on which an opinion regarding the trend of engineering practice can be formed. We have often noted how erroneous impressions are obtained from the practice of a few concerns very much in the public eye, which, however, happens not to be in accord with the general lines of progress.

In the following article the specifications of tractors gathered for the Statistical Number of AUTOMOTIVE INDUSTRIES are analyzed. Most of the data collected were published in tabular form, but some had to be omitted from the table on account of space limitations. This is the first time that we are making such an analysis, and, therefore, no comparison with previous practice is possible.

Of the tractors listed 86 per cent were of the wheeled type and 14 per cent of the track-layer type. In the latter class are included both those tractors having tracks only and those running on tracks and wheels.

Three-Plow Preponderates

It was shown some time ago by a questionnaire sent out to farmers in the state of Illinois that the majority of farmers in the corn belt of the Midwestern states consider the three-plow tractor best adapted for their requirements, and the greatest number by far of the tractor models listed are of this capacity. It is quite likely, however, that as many two-plow tractors as three-plow have been manufactured, for, although the number of two-plow tractor models listed is only 13 per cent of the total, the makers of these tractors include most of the largest producers in the country.

The one-plow tractor has only just arrived and represents only 2 per cent of all the models listed. There are indications, however, that next year's analysis will show an appreciable gain for this type, as there is a noticeable tendency among tractor manufacturers to develop machines that are specially suited to such light farm operations as corn cultivating, seeding, etc., and which when used for plowing must be hitched to a single plow.

The four-plow tractor has a greater representation than the two-plow, namely, 22 per cent, while tractors capable of pulling five or more plows make up 14 per cent of the total number listed.

Engine-Plow Ratio

The writer considered it of interest to determine the average piston displacement of two, three and four-plow tractors respectively. The comparison suffers somewhat from the fact that although most of the ratings are based on 14-in. plows, this does not hold in every case.

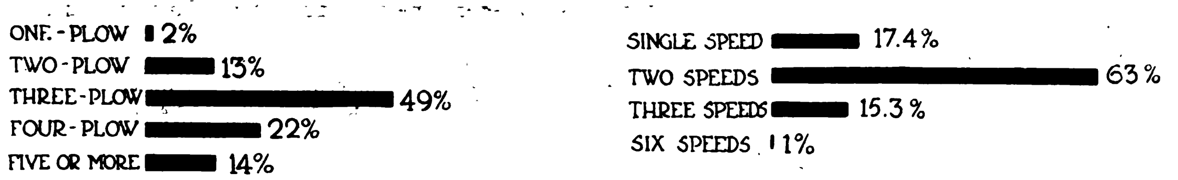
It was found that the average piston displacement of the engines on two-plow tractors is 240 cu. in.

The corresponding figure for three-plow tractors is 370 cu. in.

For the four-plow tractors it is 450 cu. in.

It will thus be seen that the piston displacements are very closely proportional to the working capacity of the tractors and plows, which is as it theoretically should be.

It is a well-known fact that a great majority of modern tractors are equipped with four-cylinder engines, and an analysis of the specifications shows that the four-cylinder and the two-cylinder together practically control the field. Only 1 per cent of the tractors have a single-cylinder engine, and the same percentage is equipped with an eight-cylinder engine. Four-cylinder



Charts based on a count of American-built tractors, showing at the left the relative percentage of one to five-plow sizes and at the right the number of speeds provided in the gearsets

engines are found on 82 per cent of the tractors and the two-cylinder on 16 per cent.

It might be supposed that all of the four-cylinder engines at least were vertical engines, but such is not the case, as is shown by the fact that only 72 per cent of all the engines are vertical, while 28 per cent are horizontal.

The following analysis of the method of casting the cylinders is limited to the four-cylinder engines: It is found that 55 per cent of the total, or a little more than half, are block cast, and 35 per cent are cast in pairs and 10 per cent are cast singly.

Motor Pump Circulation

The statement was made a short time ago in these columns that the thermo-syphon method of circulating the cooling water possessed special advantages when applied to tractor engines. A great majority of these engines are designed to run on kerosene; in order to burn kerosene successfully the cylinder walls must be maintained at as high a temperature as possible without causing preignition, and thermo-syphon circulation tends to keep the temperature of the combustion chamber walls up under certain conditions under which there would be a tendency to over-cooling with pump circulation. However, the figures show that the great majority of the engines used on present day tractors are designed for pump circulation, namely, 93 per cent, while only 7 per cent have thermo-syphon circulation.

Centrifugal Governors Lead

Almost every tractor engine at the present time is fitted with some sort of governor which governs its speed of rotation within narrow limits and prevents it from racing when the clutch is thrown out. Of the tractors listed 95 per cent carry centrifugal governors, 3 per cent hydraulic governors and 2 per cent electrical governors. It is somewhat surprising that no more extensive use is made in tractor practice of the hydraulic governor, as it is certainly the cheapest type to build, and its degree of sensitiveness is easily sufficient for tractor requirements. Of course, the diaphragm would have to be removed occasionally, but this could be done at very little cost and without much trouble.

Tractor engines generally are a much heavier type of engine than automobile engines. This would be shown by a comparison on a piston displacement basis. The greater weight of the tractor engine is due to the fact that its crankcase is usually made entirely of cast iron, besides which the bearings and all other wearing parts are made larger in proportion to the explosive pressure on the piston head. On a displacement basis the four-cylinder engines listed weigh 2.4 lb. per cubic inch. We have no corresponding figure for automobile engines and consequently are not in position to make a comparison. On the other hand, an approximate comparison on the horsepower basis is possible, as automobile engines generally weigh from 10 to 12 lb. per horsepower.

The average weight of all of the four-cylinder tractor engines is 36 lb. per belt horsepower, showing that the average tractor engine weighs at least three times as much as an automobile engine of equal output. While this difference in weight is largely due to the use of such materials as cast iron in the crankcase and to the provision of more liberal bearing surfaces in the tractor engine, another important reason is the very much lower piston speed of this engine.

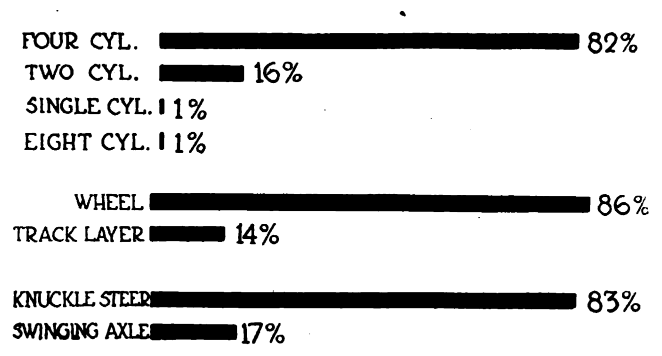
Majority Favor Gravity Fuel Feed

Gravity fuel feed, the simplest system known, is favored by the majority of tractor designers. It is employed on 88 per cent of all tractors, while 8 per cent use fuel pumps and 4 per cent the vacuum system. In the majority of tractors of what may be regarded as the most modern type, in which there is a vertical engine in front, the fuel tank is generally placed directly behind the engine, and can be easily located sufficiently high to insure positive flow under all conditions. The pump system with overflow is an adaptation from stationary engine practice, in connection with which it is used chiefly on account of its inherent safety, as there is no possibility of fuel leakage when the engine is not running. Air cleaners are used almost universally.

The following analysis of the types of oil pumps is given for what it is worth. It was obvious from the replies on the question blanks that many of those who had filled out these blanks did not fully understand the questions. The blanks enumerated gear pumps, plunger pumps and individual pumps, by which latter was meant the mechanical lubricators used on a number of engines, which usually consist of a series of small plunger pumps having a common drive. From the figures collected it would appear that 34 per cent of all the engines were fitted with a gear pump in the lubricating system; 29 per cent with a plunger pump and 37 per cent had mechanical lubricators. It may be pointed out that the comparatively large use of mechanical lubricators is due to the use of kerosene as fuel. This has a tendency to get by the pistons and dilute the lubricating oil in the crankcase, thus quickly depriving it of its lubricating qualities. With mechanical lubricators oil is fed directly to each of the bearing surfaces and no oil is ever used over.

Impulse Starters General

Magneto ignition is the almost universal practice in tractor work, only 3 per cent of the tractors being fitted with battery ignition. All except the very smallest engines using magneto ignition are equipped with impulse starters, which make it unnecessary to spin the engine when starting up in order to produce a spark. There has been much development work done in connection with impulse starters during the past 2 or 3 years. All of the early impulse starters developed for tractor service were of the semi-automatic type in which the impulse mechanism must be set by hand before it will act; but recently the automatic type, which was first brought out for automobile work some 12 years ago, has received renewed



Charts showing, at the top, the relative proportions of one to eight-cylinder engines used in American tractors and below the percentages of wheel and track drives and of methods of steering

attention. This not only makes it possible to start the engine without spinning it, but also goes into action automatically when the speed of the engine for any reason drops below a certain value, thus preventing stalling of the engine due to inability of the magneto to generate a spark at exceedingly low armature speeds.

It was found that the average piston speed of all of the four-cylinder engines was 860 ft. per minute.

All of the well-known types of friction clutches are used to a greater or lesser extent in tractor work, many of the old line manufacturers producing their own clutches, which are generally of a type familiar in stationary work. Of all of the tractors listed, 13 per cent are of the friction-driven type and consequently use no friction clutch. The various types of friction clutches are represented in the following proportions: Disk type, 34 per cent; cone type, 10 per cent; expanding type, 33 per cent; contracting type, 10 per cent. Most of the expanding clutches are adaptations from power transmission practice.

While the majority of the better known tractors are fitted with variable gears affording two forward speeds and one reverse, there are a great many tractors with both a lesser and a greater number of speeds. Thus, 17.4 per cent of the tractors have only a single forward speed; 63 per cent, two forward speeds; 15.3 per cent, three forward speeds; 3.3 per cent four forward speeds and 1 per cent has six forward speeds.

S. A. E. Standard Belt Speed Too Low

An analysis of the average belt speeds corroborates the opinion expressed at a recent Standards Committee division meeting, to the effect that the S. A. E. standard belt speed of 2600 ft. per minute is too low. The average for the tractors listed is 2725 ft. per minute.

It would naturally be expected that the wheelbase of a machine should increase with the capacity in plows, and the figures at hand show that this is actually the case, though the average wheelbase of all of the three-plow tractors and those of all of the four plow are almost identical. The wheelbase of the two-plow tractors averages up to 83.5 in., that of the three-plow to 96 in. and that of the four-plow to 97 in.

Two general types of steering gear are employed, the knuckle type and the swinging axle type. The latter was universally used on steam tractors and has been adopted by most of the manufacturers who entered the gas tractor industry from the steam tractor field. Knuckle steering is used on 83 per cent of tractors and swinging axle steering on 17 per cent.

An analysis of the tractors with respect to frame materials is rendered somewhat difficult by the fact that a practice has recently grown up of dispensing with the ordinary type of frame extending the whole length of the tractor and using only short frame members by which the engine is supported upon the front axle. Of the total number of tractors, 93 per cent have frames made of structural steel, which in nearly every case is of channel section. Pressed steel frames are used on 3 per cent of tractors and cast frames on 4 per cent. It will be understood that these cast frames are not separate frames, but are constituted by the cases of the engine, transmission and rear axle. This practice of using the cast iron machinery cases for frame purposes is rapidly gaining ground, as it reduces the weight of the tractor.

Driving wheel diameters vary within wide limits, but there is no noticeable dependence of this diameter upon the plow capacity of the tractors, as the average diameter of drivers for the two-plow tractors is 50 in. and that of the three-plow tractors 52 in.

Weights Are Decreasing

Finally comes the weight of the complete machine. This, very naturally, increases with the plow capacity, but not in direct ratio thereto. The average weight of the two-plow tractors is 3670 lb., that of the three-plow tractors 5100 lb. and that of the four-plow tractor 6050 lb. There are strong evidences that the weight of tractors of a given capacity is on the decrease. The refinements in design of various parts all tend in this direction. Lighter wheels result from the use of rolled rims of straight section, and still lighter wheels are obtained by using very thin stock for the rims and securing the necessary rigidity by flanging.

In frames a beginning has been made in the use of pressed steel, which, of course, permits of a considerable saving in weight. The elimination of separate frames tends farther in the same direction.

Determining Center of Gravity

As the question of how to determine the center of gravity of an automobile has been asked several times recently, and, so far as I am aware, no solution of the problem has been offered, the following may be of interest:

$$P'' = 2400 - 1400 = 1000 \text{ lb.}$$

so by equating the moments we find

$$P'' 60 = PX \text{ and } X = \frac{P'' 60}{P} = \frac{1000 \times 60}{2400} = 25.$$

In order to determine f accurately we must figure $f = 30 - x$ sec. $e = 30 - 25 \times 1.0075 = 4.8125$ "e" being the angle of inclination from the vertical, but

$$\text{Tan. ``}e\text{''} = \frac{7.368}{60} = .1{,}228$$

indicating that the angle "e" equals 7 deg. and the secant of 7 deg. $= 1.0075$, therefore $f = h$ Tan. e and we have ....

$$h = \frac{f}{\text{Tan. } e} = \frac{4.8}{.1{,}228} = 39.$$

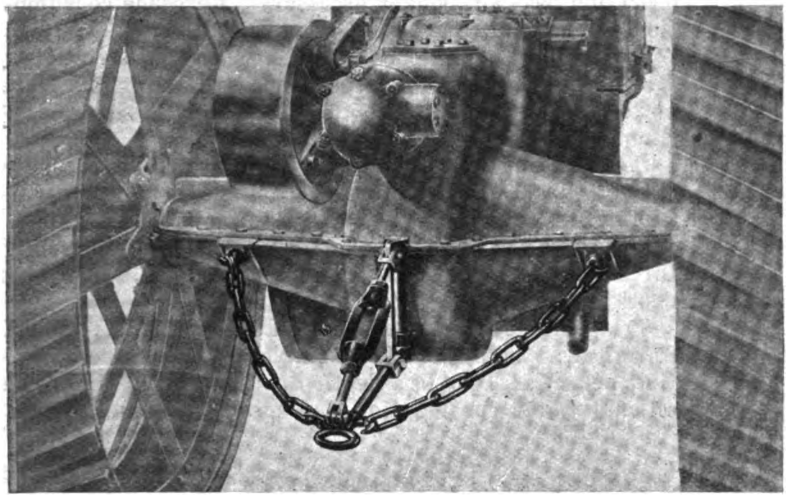
—H. E. Parsons.

An Analysis of the Hotchkiss Drive

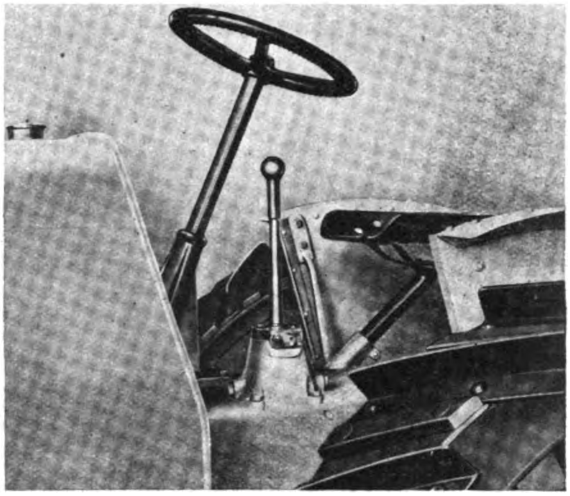
There exists a great deal of misconception in regard to the stresses imposed on the springs of motor vehicles if the torque member is eliminated.

In an article published in Automotive Industries of Jan. 23, 1919, I presented an analysis of the various forces. In this I misplaced the point of application of one component denoted with P''.

This error is pointed out by A. W. Happel in your issue of Feb. 20, and I wish to thank your correspondent.—O. M. Burkhardt.



Rear of the new Fiat tractor, showing redesign of axle housing and present location of the pulley for belt drive



Operator's seat, steering wheel and control elements of the Fiat tractor

Fiat Tractor Design Changed

Secondary Shaft Behind Axle Housing—Straight Belt Drive—Engine Bore Now 4.1

By W. F. Bradley
AUTOMOTIVE INDUSTRIES' *European Correspondent*

TURIN, Italy, Jan. 22.—Several changes have been made in the Fiat agricultural tractor since it was described in these columns Oct. 31, pages 772 and 773. On the original design the pulley for belt drive was mounted on the extremity of the propeller shaft, which necessitated the removal of one of the wheels when belt connection was made. In order to make this practicable special jacks were provided. On the machine as now produced there is a short secondary shaft immediately behind the axle housing, on which a 14-in. pulley with 7-in. face width is mounted. This gives a straight belt drive and also makes it possible to tighten the belt merely by moving the tractor ahead.

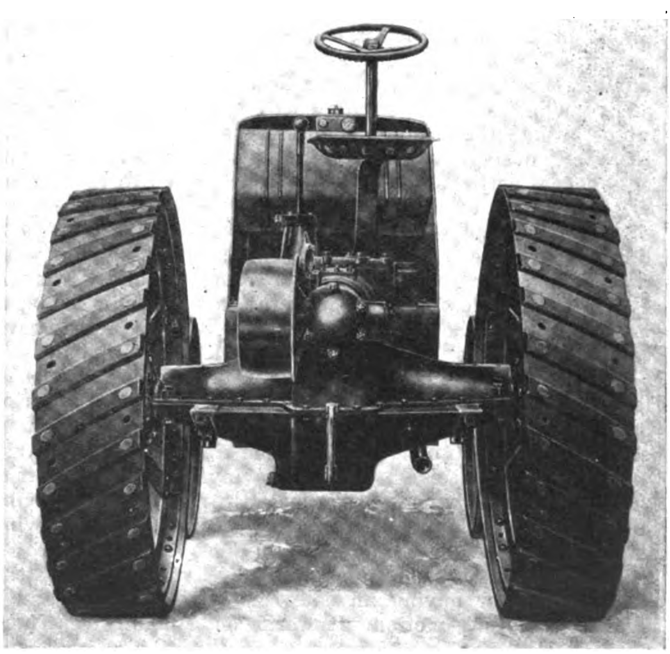
The engine was originally 100 x 180 mm. (3.9 by 7.08 in.) bore and stroke. The bore has now been increased to 4.1 in. The detailed specifications of the tractor are now as follows:

Total weight	5730 lb.
Maximum height	75 in.
Clearance	15 in.
Drawbar pull, first speed	5520 lb.
Drawbar pull, second speed	3750 lb.
Drawbar pull, third speed	2530 lb.
Wheeel track	52 in.
Wheelbase	68 in.
Minimum turning radius	122 in.
Front wheel	32 x 48 in.
Rear wheel	51 x 12 in.
Engine, 4-cylinder, 105 x 180	18/25 hp.
Diameter of driving pulley	14 in.
Width of driving pulley	7 in.
Speed on first gear	1.2 m.p.h.
Speed on second gear	2.8 m.p.h.
Speed on third gear	4 m.p.h.
Reverse speed	2.3 m.p.h.
Revolutions of pulley in forward speed	100 to 750
Revolutions of pulley in reverse speed	135 to 400

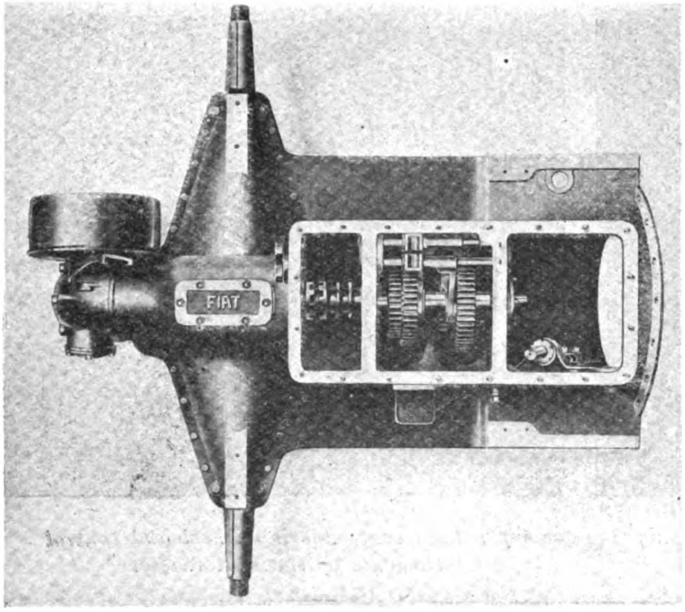
During the official plowing experiments a maximum tractive effort of 6170 lb. was obtained on first speed. On a level road no difficulty was experienced in hauling two trailers of 10 tons each and on a 12 per cent gradient the tractor has hauled a trailer of 3½ tons.

Some of the practical results obtained in open competition are as follows:

Plowing.—Soil of medium hardness plowed with a three-bottom plow at a speed of 3.7 m.p.h.; area plowed, 7176 sq. yd. per hour to a depth of 7.8 in. The soil having been sufficiently broken during this operation it was not found that the harrowing, which is done as a second



Full rear view of Fiat tractor, showing sturdy construction and symmetry of design



operation, was any longer necessary. Kerosene consumption per hour during this work was 19.8 lb.

Fuel consumption trial at Piacenza on an old meadow to be reclaimed—ground was very hard. Hammer one-bottom plow was used; depth of plowing, 12½ in.; consumption per acre, 40 lb. of kerosene.

Consumption trial at Falchera on a very wet stubble field of maize.—Parling three-bottom plow; kerosene consumption per acre, 25.4 lb.; depth of plowing, 8.6 in.

Trials on a very hard soil at Nichelino with a Parling three-bottom plow.—Consumption per acre, 40.5 lb.; depth of plowing, 9 in.

Trial on easy soil (stubble field).—Speed of plowing, 3.7 m.p.h.; Parling three-bottom plow; kerosene consumption per acre, 16.5 lb.; depth of plowing, 6.3 in. The oil and water consumption per acre was a mere trifle.

Gearset, rear axle and pulley drive of the new Fiat tractor. The 14-in. pulley is driven by a short secondary shaft immediately behind the axle housing. This location of the pulley facilitates fitting the belt and placing the tractor in the best operating position

Bethlehem Four Plow Tractor

A FIRM well known in the truck industry, the Bethlehem Motors Corp., Allentown, Pa., has recently entered the tractor field, having brought out a four-plow tractor with many uptodate features. It is an assembled product, having a Beaver 4¾ x 6 in. engine, and is rated at 18-36 hp. The total weight of the machine is 6200 lb.

In general layout the tractor is along the most uptodate lines, there being a short frame in front to which the bell housing arms are bolted. At the front of this frame there are two cross members, the forward one of which has a pivot support at the center of the front axle, while the other cross member, directly behind the first, supports the forward end of the engine on a trunnion.

All four cylinders of the engine are cast in a block, and the cylinder heads are detachable. A centrifugal governor maintains the engine speed at 900 r.p.m. Kerosene is the fuel used normally, and a supply of 14 gal. can be carried in the tank directly behind the dash board. This tank also has a compartment for gasoline for starting, of which a supply of 4 gal. can be carried. All air entering the carbureter has to pass through a Bennett air cleaner, and the air is heated by the exhaust. Ignition is effected by a Bosch high-tension magneto.

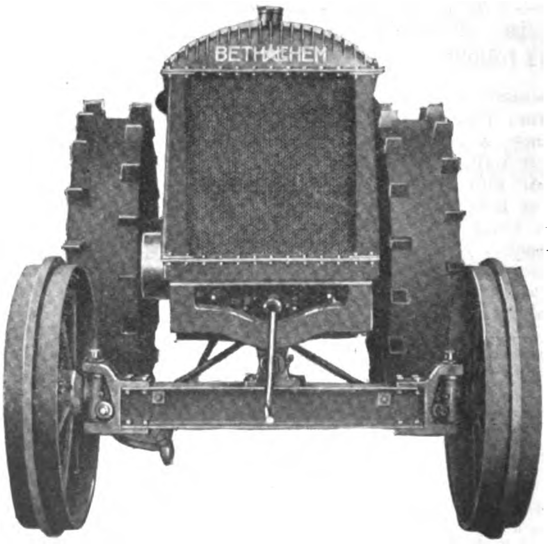
The cooling water is circulated by means of a centrifugal pump through the Fedders cellular-type radiator. This is of "armored" design, with cast-iron top and bottom tanks and cast spacers between these tanks. Fuel is fed to the Stromberg carbureter by gravity.

A Hilliard 4 plate clutch is used, together with a Foote sliding gear type of transmission which gives two forward speeds and one reverse, the former being 1.8 and 3.3 m.p.h. respectively. The final drive to the rear axle is by spur gears, and all of the gearing is inclosed. The high gear ratio from the engine to the drive wheels is 42.6 to 1 and the low gear ratio 82.2 to 1. The driving wheels are of French & Hecht make and are 54 in. in diameter by 12 in. width of rim, while the front wheels are 32 x 6 in. Hyatt and Timken bearings are used in the transmission and on the rear axle, while the front wheels have plain bearings. There is a brake drum on each driving wheel, cast directly on the driving spider. The wheels are driven through coiled springs, giving a flexible drive.

Control of the transmission gears is by the selective system, the control lever having an endwise shifting motion and a sideways swinging motion. It works on a quadrant. There is a throttle lever on the bracket supporting the gear control shaft. The clutch is arranged the same as on automobiles, being normally in engagement. It is withdrawn by means of a pedal located adjacent to the driver's seat.

Two lengths of channel steel are bolted to brackets cast on the rear axle housing and extend backward. These carry a floor board of platform steel. The drawbar is spring cushioned and the point of hitch can be adjusted laterally by means of a U-bolt passing through holes in an angle iron bar supported from the floor beams.

The tractor is steered by means of a hand wheel through a worm and wheel mechanism bolted to the side of the transmission gear housing. The front axle consists of a length of I-beam, to which steering yokes are riveted. The axle is braced by means of two radius rods connecting to a swinging beam having a swivel support at the center of a frame cross member. The radius rods are slightly inclined outwardly toward the front axle. Three point support is used for the engine. A sheet metal hood covers the power plant, being fastened to the dash board and radiator. There is a large opening in the center of this hood, through which access may be had to the overhead valves. The side openings of the engine space can be closed by means of tarpaulin curtains, which can be rolled up and strapped in place to the sides of the engine bonnet when desired.



Front view of the Bethlehem tractor, showing construction of front axle and steering knuckles

Characteristics *of a* High-Grade Standardized Engine

Greater Efficiency and Smoother Running Obtainable Better by Increasing Valve Size Than by Increasing Cylinders —Overhead Camshaft Best

By J. H. W. Kerston

THE successful conclusion of the war and the lessons learned through four and one-half years of concentrated automotive production, with practically unlimited funds available, will make it possible to offer the public machines superior in every way to any pre-war creation.

The influence of aeronautical engine practice will be particularly felt in the design and construction of new automobile engines, replacing the clumsy, heavy engine of yesteryear by a high-efficiency, light-weight motor, showing strongly the influence of scientific engineering practice.

Its lighter weight, guaranteeing better all-round efficiency, smaller fuel and oil consumption per shaft horsepower, will benefit the purchaser of a high-grade motor car equipped with such an engine, although the initial cost may be a trifle higher than that of the old-fashioned, heavy engine.

The use of steel for cylinders has been universally recognized as the standard metal for high-efficiency engines, because of its uniform structure and ability to machine the barrel outside and inside. The question in connection therewith remains as to the most efficient cooling of these cylinders—either in a unit aluminum casting or in individual waterjackets. The two recognized standard practices are typified by the Hispano-Suiza and the Mercedes. The American Liberty engine follows the Mercedes practice very closely in this respect, as do also most foreign aviation engines, as well as in the adaptation of the overhead camshaft and valve gear design with rocker arms.

From the point of accessibility, easy machining and interchangeability it must be said that the individually cooled cylinder of the Mercedes type is without the least doubt to be recommended. The aluminum casting may offer smoother lines, more pleasing to the eye, but it is also heavier than a separate cylinder jacket design.

Four-Cylinder Motor the Leader

For a high-efficiency fast car the four-cylinder motor will be in the lead, because of its four-throw crankshaft set at 180 deg., which is always in natural static and dynamic balance. For town driving the six-cylinder engine has many followers because of its throttling ability in congested traffic. V-engines will prove to be a passing fad, dictated by fashion and built to supply the fancy of a certain part of the public, rather than by sound engineering practice, for the horsepower we are accustomed to use for automobile work anyhow.

Much greater efficiency and smoother running will be accomplished by providing larger valve areas than by increasing the number of cylinders. Engines with at least four valves per cylinder will replace the multiple-cylinder engines, because they are lighter, more economical and more efficient.

The overhead camshaft with rocker arms and a vertical driveshaft with bevel gears throughout is the lightest and most efficient drive. This layout also lends itself to a very effective installation of the "accessories"; the magneto driven by a cross-shaft set at 90 deg. to the crankshaft at one end, the water pump or an additional magneto (for racing and sporting type cars) at the other end of the cross-shaft, form the most accessible installation. Where two magnetos are employed, the spindle of the water pump may form part of the vertical drive shaft. Another vertical shaft below the crankshaft may operate the oil pump. The air pressure pump and the tachometer drive will be most accessible if driven off the rear end of the camshaft. It will therefore readily be seen that in this typical layout the number of driving parts and gears is reduced to a minimum.

The employment of steel will be more general than has been customary heretofore. In an internal-combustion engine stresses for every part can be figured, and those parts can be designed and built accordingly. Steel forgings, so superior to any metal castings, will replace these, as it does away with the factor of uncertainty in castings, and consequently a great many rejections due to defects in rough castings and numerous other defects which do not show up until in the various stages of machining, with consequent additional cost of material, time, labor and depreciation of machinery.

Piston and Exhaust Valve

There are especially two parts in an internal-combustion engine in which other factors besides the imposed stresses are of paramount importance and must be taken into consideration. These are the piston and the exhaust valve. Both parts must be designed with a view of dispersing the tremendous heat quickly; in other words, the thermal conductivity becomes the most important factor. To illustrate the foregoing, a steel piston may be built lighter and stronger than an aluminum casting, yet the additional metal and consequent heavier weight of an aluminum piston is preferable, because it gives the intense heat a chance to disperse all over the heavy section of the piston skirt and from there through the oil film into the cylinder walls and into the cooling water.

The proper design of effective exhaust valves offers a similar problem. However, with provision for ample water circulation around the valve stem, no difficulties are encountered, especially in the four-valve-per-cylinder-head design, where the use of two smaller valves instead of a single large one prevents overheating and consequent warping, usually found in large-diameter valves of the old type.

In this connection another point is apparent. With the employment of two smaller valves instead of a single very large one, lighter valve springs may be used. The next step forward is then the employment of two valve springs for each valve, which has the added advantage of enabling us to use two very light springs of about 20 to 30 lb. pressure each, instead of one large and extremely stiff spring of, say, 65 to 85 lb. pressure. These stiff springs are, of course, more liable to breakage at high speeds due to crystallization of the steel, and at certain critical speeds synchronism of the spring will prevent the proper seating of the valve stems on the cams.

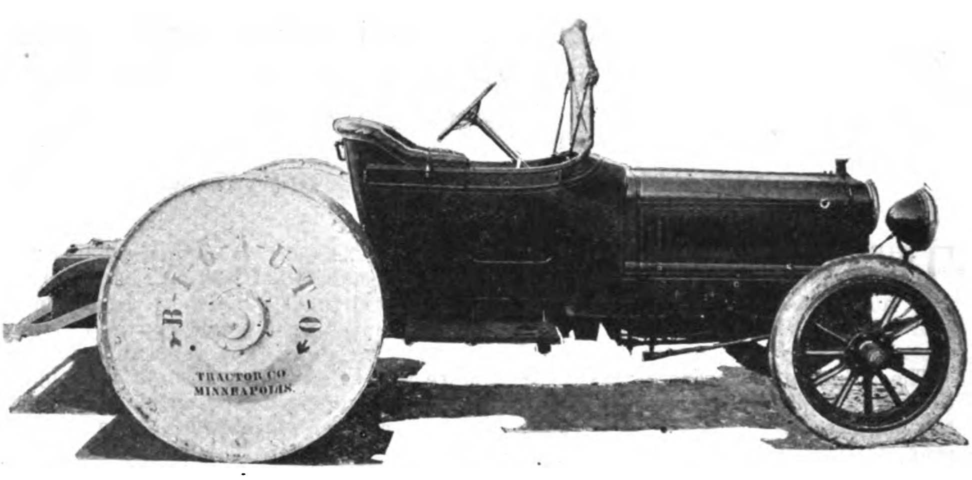
(*Continued on page* 549)

The Big Auto Tractor Attachment

A Conversion Unit for Converting Large Touring Cars of Older Models Into Farm Tractors—Outfit Weighs About 2500 Lb.

TWO or three years ago, after the truck conversion unit for Ford cars had proved a great commercial success, similar units designed to convert Ford cars into farm tractors were placed on the market. These, however, do not seem to have proved as successful as the truck attachments, and little has been heard of them recently. One of the reasons undoubtedly is that the Ford passenger car engine hardly has sufficient power for operating even a two-bottom plow, if the soil is at all heavy.

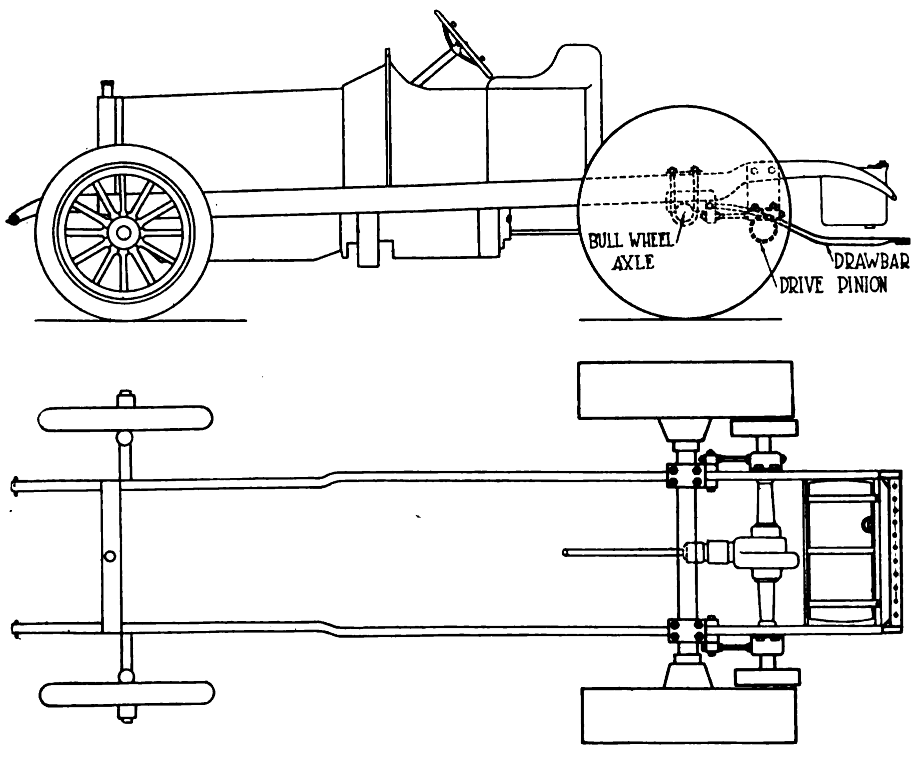
More success is likely to attend the effort to introduce a conversion unit for automobiles of larger type. Large touring cars of either the four or six-cylinder type, such as sold about six years ago at from $2,000 to $3,000, can now be "picked up" at a relatively low price. They are not sufficiently up-to-date to suit the requirements of the original owners, and they do not appeal to the man who is looking for a second-hand car because of their high cost of operation. The power plants of these touring cars usually are powerful and sturdy, as are their transmissions, and the material used in these machines was of the highest grade. Therefore, provided the engine is of sufficient capacity, so that when drawing its normal rated number of plows it will not be overloaded, and provided it is still in good working order, it should be capable of giving very satisfactory service.



Attachment applied to a Winton car

A conversion unit for transforming cars of the above described class into farm tractors has been placed on the market by the Big Auto Tractor Co., Minneapolis, Minn. Their attachment has been manufactured during the past two years, and has been supplied mainly to farmers who already owned cars of earlier models which were sufficiently powerful for the purpose. Attachments have actually been fitted to the following makes of cars: Glide, Buick, Packard, Russell-Knight, White, Inter-State, Hudson, Locomobile, Stearns, Case and Welch.

The design of the attachment may be studied by means of the accompanying illustration. There are two steel disk wheels, 48 in. in diameter, which are provided with internal gear rings, which are bolted in place. A 14-tooth spur pinion is secured to each end of the axle shaft, after the rear wheels have been removed. As the seat of the driving flanges or rear wheel hubs differ in all cars, these pinions have to be fitted separately for each make of car. To the car frame, ahead of the rear axle, is secured a 9-in. channel steel beam, to which is bolted a heavy cast iron bracket which receives the 3¼-in. round axle, the latter being closely fitted and pinned in place. This bracket is also trussed by means of two tie rods underneath. A flange at the rear of the bracket has holes drilled through it to allow of raising and lowering the drawbar, and there is another flange at the bottom of the bracket which has the radius rod connected to it, by means of which the mesh of the gears can be adjusted. A filler is inserted into the frame channels where the brackets go, and is held in place by means of heavy U-bolts. The object of these fillers is to strengthen the frame members. In addition to being adjustable up and down, the drawbar is provided with a number of holes in its transverse member, so that adjustment can be made to shift the draft.



Elevation and plan of converted machine, showing the general layout

On each end of the main axle is pro-

vided a thrust collar which takes the thrusts in both directions. A thrust collar cap is screwed on the outer end of the wheel hub so that the collar may operate in oil. Oil grooves are cut radially into the faces of the thrust collar, and provide for efficient lubrication of the thrust surfaces.

When the conversion from automobile to tractor is made, the rear springs of the car are removed, and are replaced by a heavy plate and angle, which insures a rigid connection between the frame and the spring plate on the rear axle housing. Vibration is taken up on a wood liner. The large roller bearing in the rear axle is utilized to take the pressure due to the transmission of power by the bull pinion. The internal gear ring secured to the driving wheel has 48 teeth, giving a reduction from the car axle of 6 to 1. The drawbar is attached to the axle bracket, and therefore is independent of the car body. It is suggested that a heavy open tool box be carried on the back of the car frame, which comes in very handy in plowing, as extra plow bottoms, chains, etc., can be carried in it.

Old Front Wheels Usually Retained

We understand that most of the users of the Big Auto conversion unit continue to use the front wheels with their pneumatic tires. In some cases these tires are filled with a so-called tire filler, which permits of their use until the tires practically are in shreds. The Big Auto Tractor Co., however, makes a wood felloe with steel tire 6 in. wide, to which is shrunk a skid ring, having a ¾-in. square section. The tire is 5/16 in. thick. The wood felloe is strongly built up and ironed. These wheels are special and are not included in the regular unit, the price of the wheels depending upon the conditions.

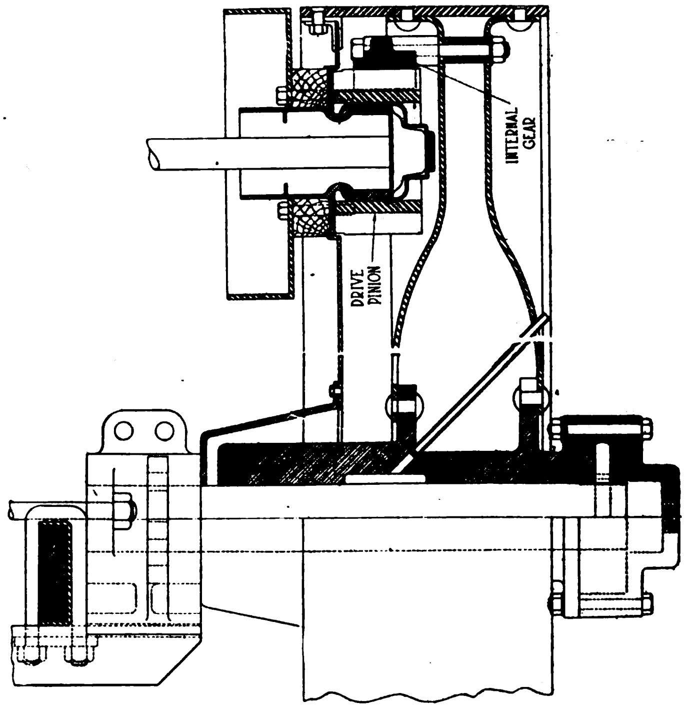
It has been found that when these large cars are used for tractor purposes, owing to the low speed at which they are operated, their cooling equipments are not adequate for the requirements. To overcome this difficulty an auxiliary tank is sometimes carried on the running board. This can be easily attached, and connected up in such a manner that the water circulated by the pump, after passing through the radiator, passes through the auxiliary tank on the running board, and then to the engine jacket. This increases the cooling area as well as the water capacity. To make up for the reduced air circulation, due to the low speed of the tractor, the fan must be geared up higher, which can be done by changing the driving pulley or gear, and, besides, it is advantageous to give the fan blades a larger angle, which can be easily done by means of a wrench. In some cases, where the cooling capacity is far from adequate, an additional fan has been installed in front of the radiator, and provided with a hood, to direct the air and protect the fan.

In designing the driving wheels, special attention has been given to the protection of the pinion and gears from dust and dirt. The gear wheels are protected on the outside by the solid disk of the driving wheel, and on the inside by a steel sheet with an accurately fitting opening for the pinion. This steel sheet does not revolve with the wheels, but is fitted close, and by the use of heavy grease all sand and mud is said to be excluded, the grease also serving as a lubricant for the gear and pinion.

Disk Wheels Stand Hard Service

The Big Auto Tractor Co. states that it developed a disk wheel after having in its early models used various kinds of spoked wheels with ill success. It was found that the spoked wheels would not stand usage on stony roads, but no trouble has been experienced with the steel disk wheels under such conditions.

The weight of the complete conversion unit is 2500 lb., and the average weight of a big car chassis stripped for the tractor as described is also about 2500 lb., making the total weight of the tractor 5000 lb. Of this nearly three-fourths is on the rear wheels, so that ample traction is secured under practically all conditions. It is stated that the conversion of a big car into a tractor by means of the unit described takes a handy man about one day. Occasionally he will require help from another person, especially in lifting. The tractor can be used not only for plowing, but also for hauling purposes, for road building and similar work. It has been found



Section through Big Auto tractor wheel, showing internal drive from old car axle

that the average period of use of a tractor in plowing is only 3 months per year. As the gear reduction from the rear axle to the tractor driving wheels is 6 to 1, and these wheels are larger in diameter than the car wheels, speeds of upward of 10 miles may be obtained with the tractor on the road, if the road conditions permit. With the semi-trailer attached, the tractor can be used for hauling grain and other produce to market. Where heavy hauling is required, three wagons carrying 3 tons each can be drawn by the machine. It is also possible to reconvert the car for touring purposes, but the advantage of this is not emphasized by the manufacturers.

The driving wheels revolve on a solid steel axle and have a bearing surface 16 in. long, which is lubricated by means of grease cups. Two types of lugs are furnished, a cone lug for plowing on sod and an angle lug for use on hard roads and soil. The latter, it is claimed, can be used on any street without damage. Both wheels have holes 4½ in. apart on each side, so that any type of lug can be applied. For use on very light or soft soil, extension rims can be attached.

Editor, AUTOMOTIVE INDUSTRIES: In your issue of Dec. 19, on page 1065, you have a little article stating "Goodyear Patent Is Not Infringed."

In the last paragraph of this you state that Firestone discovered new evidence in the form of a Belgian patent of 1906 and that a replica of the machine, the original having been purchased from Mathern in 1909, was set up in the court room. Now, this part of the information is all incorrect. The Belgian machine, issued under a patent to Mathern, was first introduced in this country by the Hood Rubber Co., who purchased the first machine. The machine was put into evidence, with affidavit of the writer regarding the facts, and was furnished to Firestone for entering into the suit.

The machine, following the decision, has been sold to the Firestone company, so that they could keep it in evidence for future suits.

The right to manufacture under this patent is held by the Hood Rubber Co. in this country. Furthermore, Firestone did not discover the evidence. It was offered to them through our attorney for their first suit in the lower court and was not accepted. There is no question but what the Mathern machine represents the machine building of automobile casings even prior to the time of the Seiberling and Stevens machines in 1904, having been widely operated in foreign countries prior to that time.—Hood Tire Company, Watertown, Mass.

Follow-Up System for Engineering

Checks Up Thirty Jobs at One Time—Cards Arranged To Indicate All Stages of Work

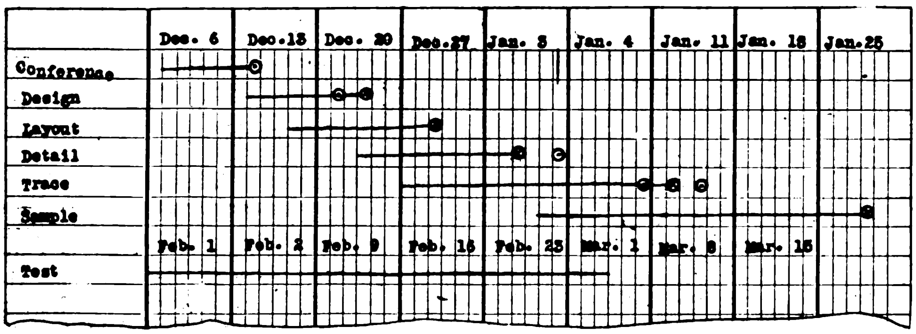
AN interesting system is in use by the Standard Parts Co., Cleveland, Ohio, to follow-up engineering, or any other work which requires definite steps of progression, from the time it is started until it is completed. The system is simple and at the same time allows an executive to follow up readily the different steps in his work. It is applicable to any kind of executive work, such as sales, production, collection, financial matters, etc. The system was invented by Major Lewis T. Kalb, who has now joined the Standard Parts Co. as an assistant to J. G. Utz, director of engineering. He used the system in the work of the engineering division of the Motor Transport Corps, where the great volume of work necessitated some such method of keeping in touch with the progress on different jobs, and at the same time allowing none to lag. There were over 350 persons employed in the engineering division of the Motor Transport Corps, including draftsmen, clerks, testers, etc., and this system was used for following up the design, testing, sending out of prints and keeping a record of all vehicles used by the Motor Transport Corps.

Kept Record of Thirty Jobs at One Time

By the use of this system as many as thirty different jobs were carried on at the same time and an accurate check-up of the progress of each maintained. In addition to the designed jobs there were perhaps sixty or seventy testing jobs and thirty or forty sets of specifications to get out. Naturally, it is impossible for the head of such a department to carry this work in his mind and some sort of follow-up is necessary. The scheme outlined herewith was found to be very satisfactory and is adaptable to a wide variety of uses. The method consists of the utilization of 5 by 8 in. cards for each job. On one side is typed all of the information pertaining to the work, such as specifications, the date of release, etc. The other side is ruled for a follow-up chart, as shown in the accompanying illustration. The horizontal rulings on the chart indicate the various stages through which the work must pass before it is completed, and the vertical rulings indicate periods of time, such as days and weeks. When the work is started the weeks are typed in, as shown in the illustration, designating each week by the month and date of the first day, or Monday. If the operations are definite and known in advance they may be typed at the time the job is started, or if definite steps are not certain they may be typed in as each successive stage is reached.

As each stage is reached the man in charge of this particular phase of the work is consulted and the probable date of completion is determined. This is shown by a bull's eye on the card. Each day that the work progresses a mark is put in the space for that day and for that stage of the work. It is thus possible for anyone to determine, by consulting the card, just how far along the job has progressed. It is possible to tell what stage it is in at the present and the probable date of completion, and in fact all of the important facts that the executive wants to know regarding it. The bull's eye makes it possible to check up when any definite period of time allotted for any stage of the work has elapsed and indicates whether that particular department of the work is up to or below its estimate. In this way it is possible to put on more men should they be necessary to insure the job being kept up to program.

It is very common practice not to look for a job until the date it is completed and then to find that the work has been neglected, or shelved for other jobs, with the result that the promised date cannot be met. In addition to acting as a follow-up system, the card also becomes a valuable record and furnishes a ready clue as to what can be expected in future jobs of a similar nature. The system, if desired, could be elaborated to indicate the number of men hours spent on any job, or the card could be used as a time record by key marks for the particular man on the job and accurately telling the length of time spent on the work. If not desired as an accurate time record, it could be used as a check against more complete time systems used by a factory. The real merit of the system is its simplicity and its ability to be used in a wide variety of applications.



Typical card of the DeKalb system used for following up engineering and other executive work

Reconstruction Will Demand New Machinery

THE Oakland Motor Car Co., Pontiac, will not continue the manufacture of pants. The upholstery department of this concern was turned over to the manufacture of trousers for soldiers' uniforms during the war, but of course is swinging back to tops and seat covers, now that hostilities have ceased. The alterations necessary in getting into the war manufacturing program and back again to a peace basis have furnished an opportunity for revising the equipment which in the stress of previous competition did not exist.

Soon again the material market and the dealer organization will have been swung back into line and the old order of things will, in a large measure, have returned. There is going to be an interval before that time, during which manufacturing methods and machinery are going to be thoroughly rearranged so the best possible conditions for the commercial race will exist. Everywhere in the automotive world, particularly in the passenger car, truck and tractor fields, designers are busy on new products. As soon as these designs are complete and the experimental models have been carefully tested, production facilities must be arranged and manufacture started. This is going to mean the greatest demand for special machinery that the automotive world has ever witnessed.

AN inquiry has been received for C. K. Salisbury, writer of a letter on constant compression engines which appeared in AUTOMOTIVE INDUSTRIES for Nov. 28, 1918. If Mr. Salisbury will send us his address we will communicate it to our inquirer.

Packard Exhibits Its First Commerical Plane

Has Line of Three Engines and Plane Designed to Take Eight-Cylinder Power Plant—To Be Marketed Through Packard Sales Organization

IMMEDIATELY after the armistice was signed the Packard Motor Car Co. began to consider the matter of turning its war experiences in the airplane field into commercial channels. The factory, having been tooled up and laid out for the production of Liberty aircraft engines and having already commenced the manufacture of the La Pere type of plane, found itself in an advantageous position to swing over to commercial airplane production should a demand be found for this product.

Based on the assumption that in this country there are hundreds of wealthy sportsmen to whom flying would appeal, the Packard company has already designed and brought out its first line of airplanes. These will be made at first in limited quantities and marketed through the Packard dealer organization. Some of the dealers have already placed their orders for planes and are now reporting sales to users.

In designing the planes and engines, it has been the aim of the engineering department of the Packard company to incorporate the best features of the Packard and Liberty aircraft engines developed before and during the war. It has been found possible to eliminate some of the objectionable features of the previous types, these largely having to do with installation difficulties. The changes have resulted in a material saving of weight in the completed plane, as well as giving greater simplicity in design and more reliability in performance.

Some of the important alterations may be mentioned. For instance, the carbureter is now located on the bottom of the crankcase, with the necessary intake passages carried through the case. This has resulted in a very low carbureter, making possible the use of simple gravity feed for all types of planes. At the same time the intake

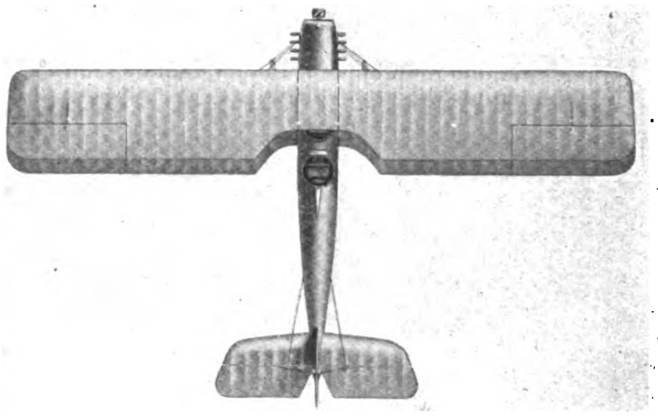
Fuel range wide open at 10,000 ft	3.5	hr.
Fuel range wide open at 15,000 ft	4.0	hr.



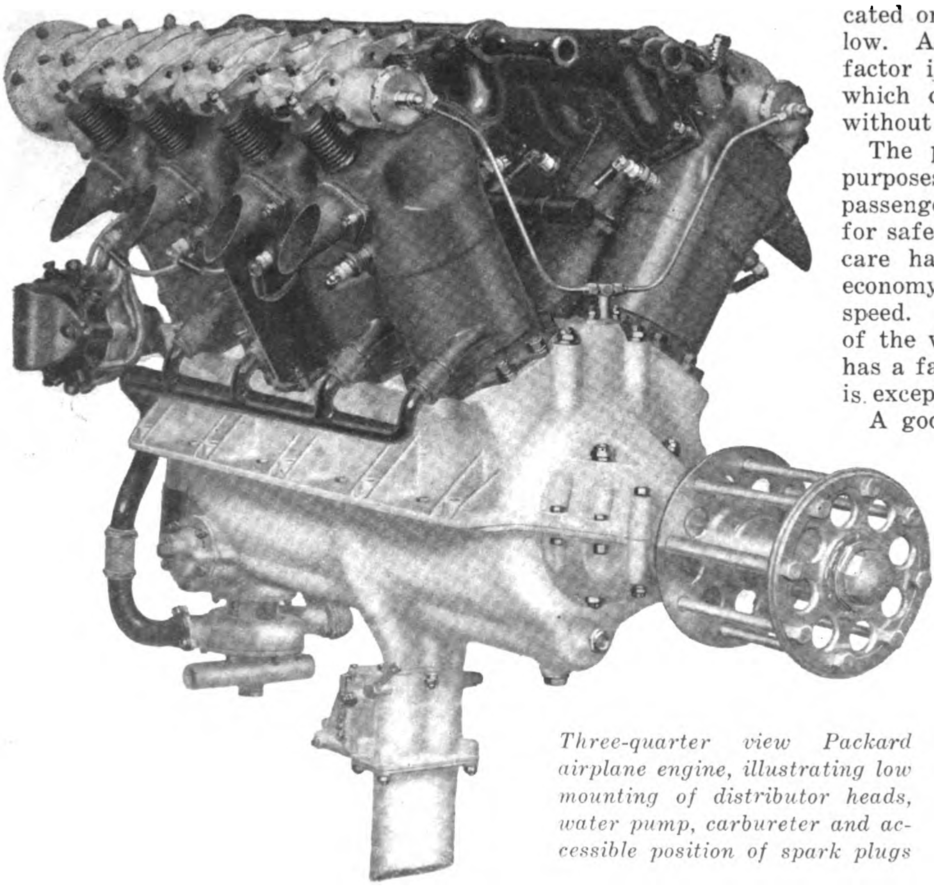
Plan view of the Packard airplane. Note the form of the planes and the visibility from pilot's seat

passages are kept properly warmed and the weight required for water-jacketing the intake is eliminated. Furthermore, removing the carbureter from the V leaves the space between cylinders entirely clear, giving greater accessibility for the spark plugs and providing for unusual vision.

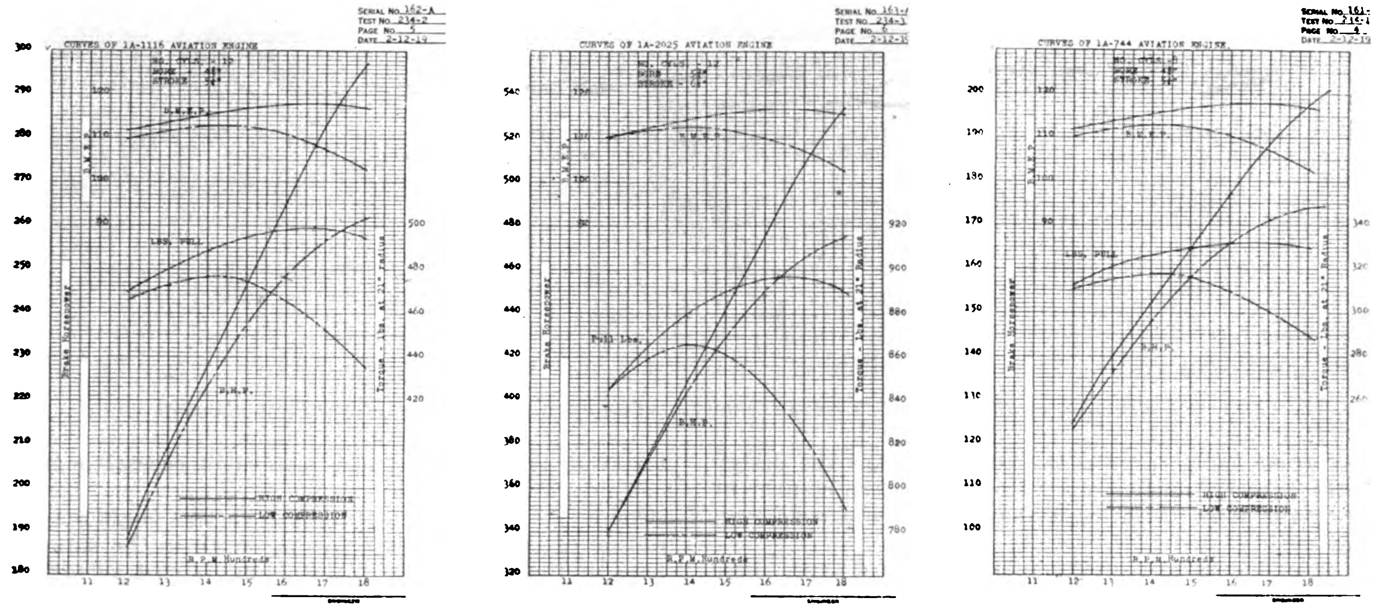
The water pump is located underneath the crankcase. The oil pump is located low down on the left side and the oil pump screen and blow-off valve are also located low on the right side. Another unit to be mounted lower than formerly thought possible is the ignition distributor head, the head for each set of cylinders being located low down on that side of the engine. All of these units are made very accessible for examination or adjustment through convenient openings in the engine cowl. The generator is placed in a saddle carrier in the V and is quickly detached for examination and adjustment. The starting motor is also very accessibly placed, being located on the rear of the engine and quite low. Accessibility has been made a prime factor in the design and there is nothing which cannot be reached with ease and without removing any other part.

The plane, being utilized for sporting purposes largely or for cross-country fast passenger transportation, has been designed for safety and speed, and at the same time care has been given to have reasonable economy and comparatively low landing speed. The plane is designed to make use of the very best materials obtainable, and has a factor of safety of over seven. This is exceptionally high in plane construction.

A good idea of the arrangement of the machine, which is a two-passenger biplane, is given by the sectional illustration herewith. It will be noted that a clothing compartment is provided, also a suitcase compartment to carry two suitcases, which will be found very convenient in cross-country traveling. The plane illustrated herewith has been designed around, and to be a complete unit with, the 1-A-744 engine, which is an eight-cylinder type of 160 hp. at 1525 r.p.m. The general specifications of the plane are tabulated herewith. The per-



Three-quarter view Packard airplane engine, illustrating low mounting of distributor heads, water pump, carbureter and accessible position of spark plugs



Performance charts of the three Packard aviation engines as calculated by the Packard engineering department, based on previous similar designs

formance, as will be noted from the charts, is estimated.

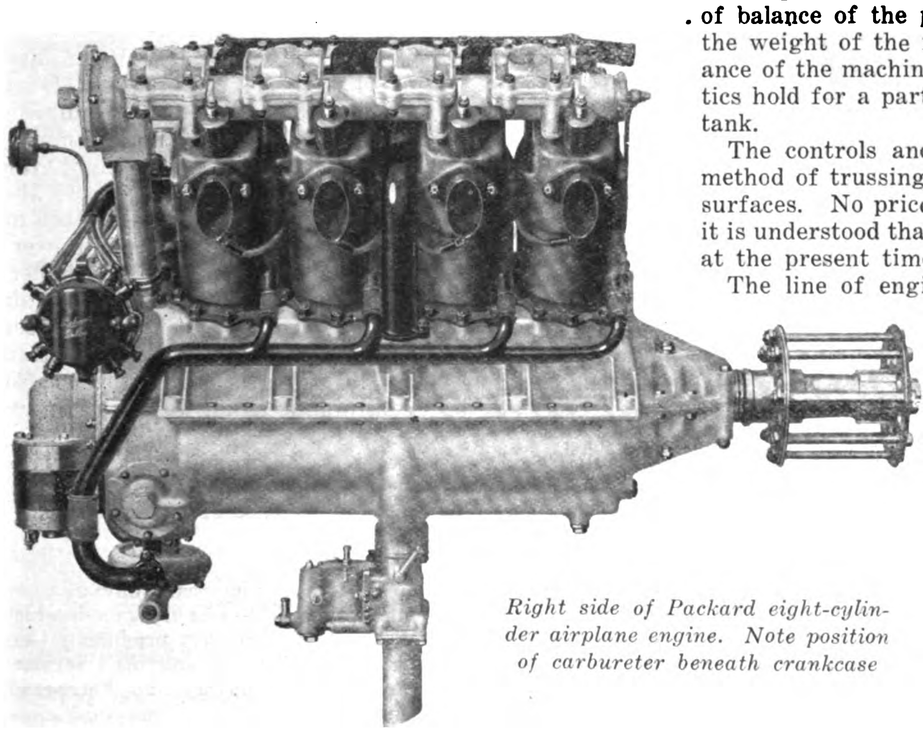
The Packard company is not in production on this plane at the present time, but it will probably go ahead with its manufacture, and in this event, before placing the plane actually on the market, exhaustive sand tests and other tests will be made under official supervision. Before any deliveries are made to customers a sand test will be made on each plane and a copy of the sand test report will be furnished to the purchaser, so that he may be fully informed as to the strength of the various units.

It is estimated that the plane will fly about 100 m.p.h. with full load on account of its comparatively light weight and clean-cut design. The landing speeds have not yet been determined, but it is claimed that they will be quite low and probably about the same as the usual primary training machine. To further facilitate landing in unknown and rough fields, the landing gear is located well forward to guard against nosing over and a rugged tail skid is provided to take care of unusual strains and shocks.

One of the features of the plane is the attention given to the comfort of the passengers. For instance, the engine is entirely housed in, making it impossible for oil or gases to blow back in the passengers' faces and the passengers are guarded against drafts by bulkheads on each side. This is a feature which will be appreciated by those who have been out in disagreeable weather.

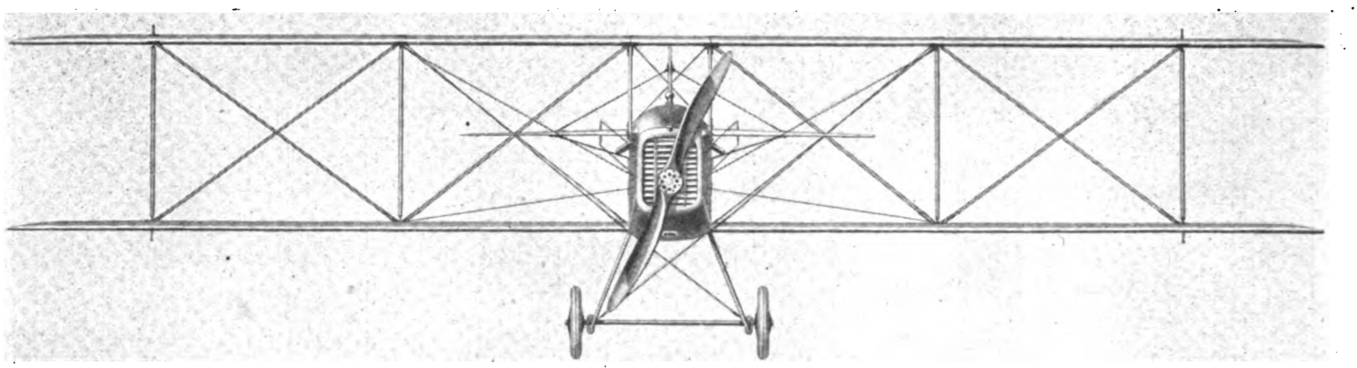
The rear cockpit is arranged especially for the pilot, but the necessary dual controls are provided, so it can be flown from the front seat, thus making it possible to use this machine for instruction work when desired. The controls in the front compartment can be lifted out quickly, making it impossible for the passenger to interfere with the control of the plane, should this be desired. The gasoline tank is located between the passenger and the engine. This location, at approximately the center of balance of the plane, takes care of the variations in the weight of the fuel without interfering with the balance of the machine, so that the same flying characteristics hold for a partially empty tank as well as for a full tank.

The controls and fittings are standard and a strong method of trussing is used to properly support the wing surfaces. No price has been set on the plane as yet, but it is understood that it will sell somewhere around $15,000 at the present time.



Right side of Packard eight-cylinder airplane engine. Note position of carbureter beneath crankcase

The line of engines includes three models of similar design. Two of the models, known as the 1-A-744 and the 1-A-1116, use the same 4¾ by 5¼ in. cylinders, the 1-A-744 being an eight-cylinder and the 1-A-1116 being a twelve. In addition, there is a larger engine, using 5¾ by 6½ in. cylinders, twelve in number. The general characteristics and arrangement of these engines follow along similar lines. They are all V-type engines having an inclined angle of 60 deg. The eight-cylinder type has a five-bearing crankshaft and the twelve-cylinder design has seven-bearing crankshafts.



Front elevation of the Packard airplane, showing wing span and absence of parasitic elements

In a great many respects the engines follow the design of the Liberty, particularly in respect to the manner of taking the drive off the crankshaft for the overhead camshaft.

The cylinders are of the individual steel type, these having been adopted on account of their lightness and because of the advantages of water circulation and easy valve cooling with this type. The pressed steel jackets are welded on in a manner similar to that employed on the Liberty engine.

The pistons are aluminum die-cast, equipped with a floating piston pin, and an arrangement of rings to prevent fouling of plugs when coasting down from high altitudes. The valve drive is similar to that used in the Liberty engine, being of camshaft and rocker arm type, the drive being taken off the crankshaft by a bevel gear and carried upward through a vertical shaft to the overhead camshaft. The valves are 2 in. in diameter in the clear, with 30 deg. seats. The intake valve lift is 7/16 in. and the exhaust 3/8 in. This large valve size is claimed to produce a very high mean effective pressure even at speeds of 1800 and 1900 r.p.m.

Performance Curves

The performance curves of the various engines are given in the chart herewith for both the high and low-compression cylinders. The brake mean effective pressure curves are shown for both compression ratios. These curves are calculated curves, but owing to past experiences with engines of this type will be found closely to coincide with actual results. The cylinders in this type of engine are exactly opposite each other, as the straddle type of connecting-rods are used, these rods having proved themselves satisfactory in the Liberty and other types of successful war airplane engines.

Lubrication is by full pressure feed, the system being very similar in many respects to the Liberty engine lubrication, the camshafts being taken care of by independent leads through the hollow shafts.

The engine is designed especially for the use of a nose type of radiator, but can be attached to any other type of radiator arrangement. The water pump is driven from the lower end of the vertical shaft and rests horizontally beneath the engine, allowing a straight lead to be carried back from the radiator. The water pump is equipped with an automatic spring take-up for the stuffing box and is readily accessible, due to the fact that it is clear of the engine beneath the crankcase.

Ignition is by the Delco system which incorporates the newest Delco improvement in which the head remains stationary and the spark advance is secured by advancing the drive shaft. Complete double ignition is supplied to two sets of spark plugs and the engine will function properly on either set. The location of the ignition distributor heads is such as to make them easily accessible from each side of the fuselage.

One of the important innovations in this engine is the location of the carbureter. As is shown in the exterior views of the engine, the manifolding is cast integrally with the lower half of the crankcase, thus permitting an exceptionally low location for the carbureter. Not only is this an advantage from the standpoint of being able to use gravity feed, but it also readily permits of the air intake being carried through the bottom of the plane, thus eliminating any danger of fire in starting a heavily primed engine.

The matter of weight has been carefully worked out in all three engines. The eight-cylinder engine weighs 520 lb. complete; the smaller twelve weighs 710 lb., and the larger twelve 1000 lb. The weight of the engine is given complete with the propeller hub, carbureter, ignition distributor heads, ignition switch, generator, starting motor and starting switch. To this may be added, for engine equipment, 40 lb. for the cranking and ignition battery and the weight of the water system. What this weighs may be judged from the eight-cylinder, in which the water contained in the cylinder jackets, pump and pipes weighs 25 lb. The radiator holds 27 lb., giving the total weight of 52 lb. of cooling water. For the eight-cylinder engine, which uses a 4-in. nose type of radiator of tubular type, the radiator weight is 73 lb.

The engine is 14½ in. from center to center of the bed timber bolts, the extreme width overall being 27½ in. The highest point above the bed timber is 20½ in., and the necessary distance between the radiator and front bulkhead for proper mounting 34 to 36 in., these dimensions applying to the eight-cylinder. On the smaller twelve, employing the same cylinders as the eight, the engine is 12 in. longer. On the larger twelve with the 5¾ by 6½ in. cylinders, the center to center distance of the bed timber bolts is 16¾ in.; the extreme width overall, 30½ in.; the highest point above the bed timber, 23½ in., and the necessary distance between radiator and front bulkhead, from 52½ in. to 54½ in. The nose radiator in the case of this engine is 5 in. thick instead of 4 in., and weighs 110 lb. This is one of the largest aircraft engines designed to date, but it is very compact.

ALTHOUGH all private use of automobiles was prohibited in Great Britain last year, that country imported 193,074,560 gallons of gasoline, an increase of nearly 54,000,000 gallons over 1917.

IN Helsingfors, the capital of the new Scandinavian country, a Finnish Air Traffic Co., Ltd., has been formed, which will in co-operation with the large aircraft producing German firm, A. E. G., run daily passenger and mail services between Helsingfors and Riga, Helsingfors and Petrograd, and Helsingfors-Stockholm via Abo.

The Altitude Engine Test Laboratory

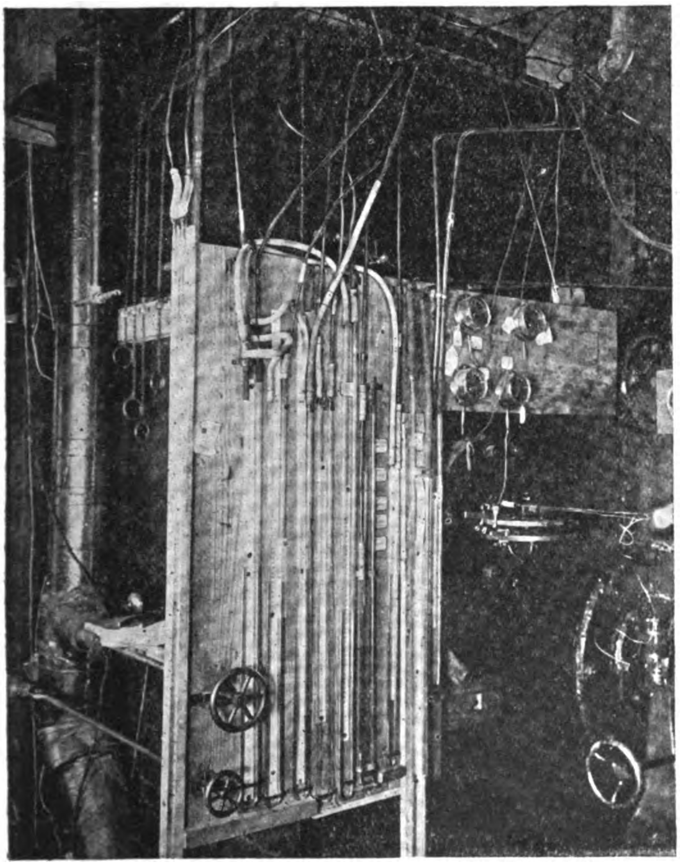
Installed for the Advisory Committee of the Bureau of Standards to Make Tests on Airplane Engines Under Conditions Duplicating Those Met With When Flying at High Altitudes

By P. M. Heldt

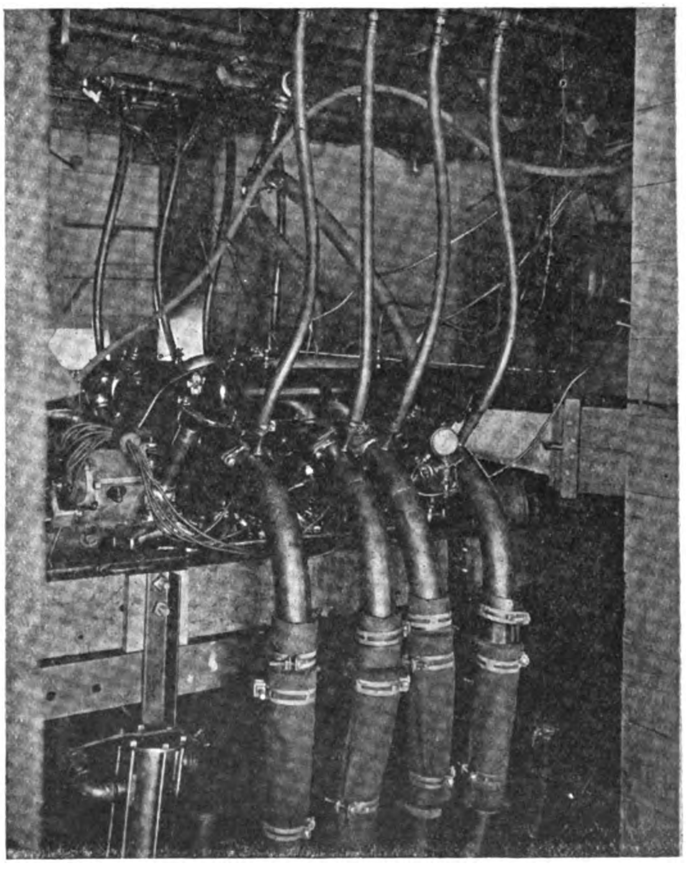
AIRCRAFT engines are required to operate mainly at high altitudes, and the performance of an engine under the conditions of low atmospheric pressure and temperature obtaining at these altitudes largely determines its practical value for aircraft work. It is as yet impossible to make complete tests on an engine during a flight. After the first experimental models of the Liberty engine had been completed, two sample engines were taken to Pike's Peak, Col., and tested out there. This, however, is a rather remote place, and besides the top of this mountain does not represent the limit of altitude to which airplanes are required to ascend. So it was decided to construct an "altitude chamber" at the Bureau of Standards in Washington in which conditions of engine operation at high altitudes could be closely reproduced. The altitude laboratory was completed more than a year ago, and has been in almost continuous use since, although some changes have been made in the equipment from time to time which facilitate the tests and tend to give more accurate results.

The altitude laboratory consists of an airtight chamber of reinforced concrete from which the air can be exhausted to such an extent as to reduce the pressure within to about one-third atmosphere, if desired, a centrifugal Nash turbo-blower being used for this purpose. While the pressure of the air within the chamber is being reduced, its temperature is at the same time lowered to a degree corresponding approximately to that observed at the altitude which is to be simulated. This necessitated the installation of refrigerating apparatus in the form of a set of coils located within the chamber, over which the air is passed by means of electrically driven fans. These fans keep the air within the chamber in constant circulation, thus tending to facilitate dissipation of the heat given off by the engine and to maintain the temperature of the air constant throughout the chamber.

The power developed by the engine is measured by an electric cradle dynamometer located outside the chamber, which is connected to the engine by means of a flexible shaft. All of the devices required for making temperature and pressure observations are mounted outside the altitude chamber and are connected to the engine by means of tubes, wires, etc., extending through the chamber wall. Means for the control of the engine are also located outside the chamber, thus enabling the tester to vary the conditions of operation.

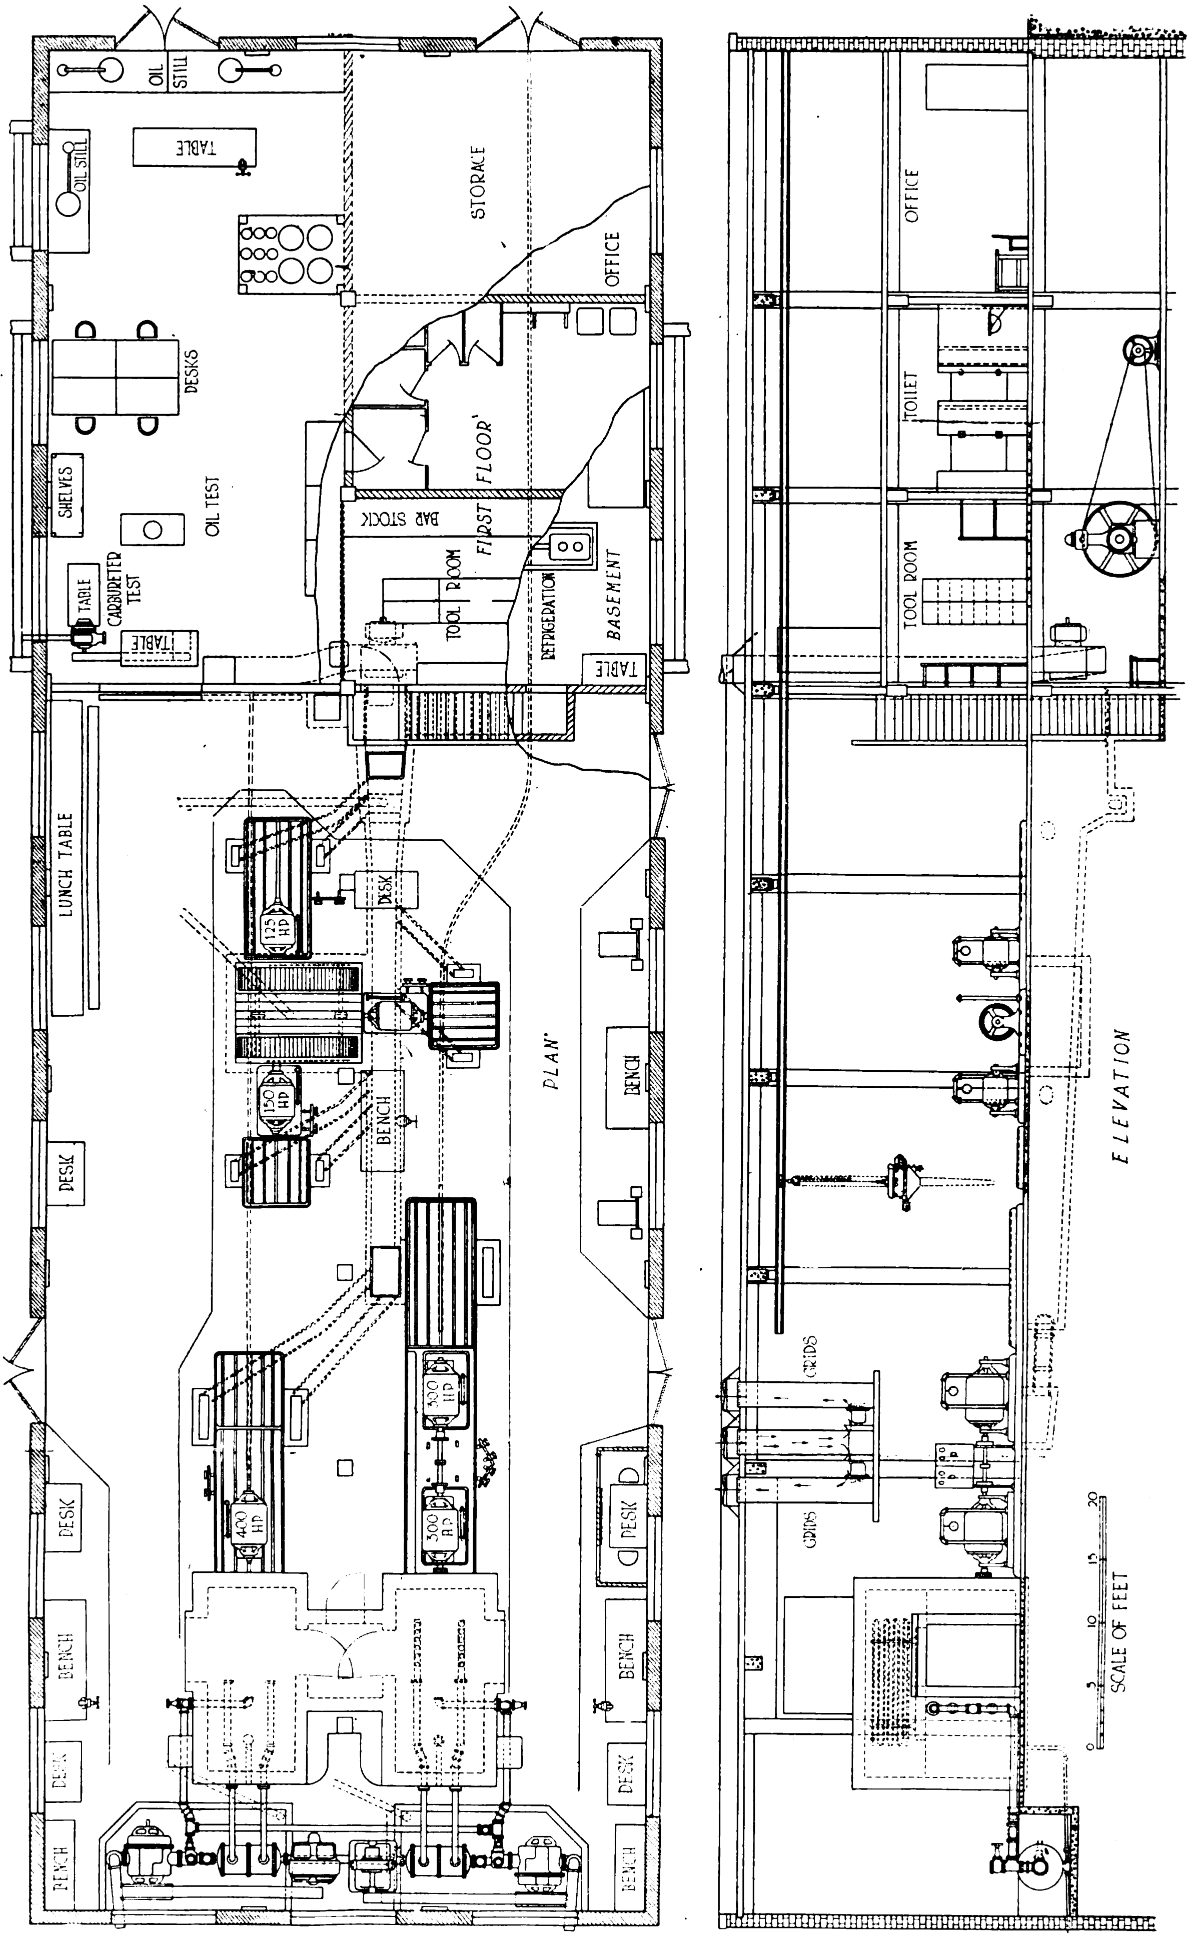


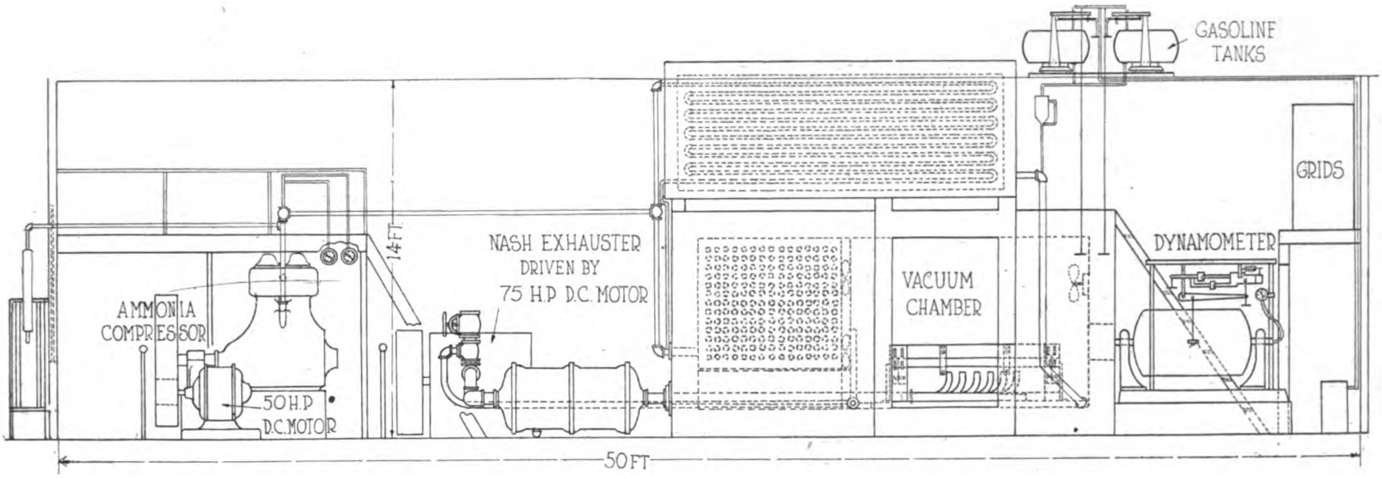
Pressure gage board of altitude chamber



Liberty engine in vacuum chamber

Plan and Elevation of the New Altitude Laboratory





Elevation of the present altitude chamber, Bureau of Standards

Originally, because of the haste with which the installation had to be made, the altitude chamber was installed in a temporary frame and stucco structure 24 x 50 ft. in dimensions. Later on, however, the present altitude laboratory, together with a duplicate one, will be installed in a concrete and brick building especially designed for the purpose.

Roominess Essential

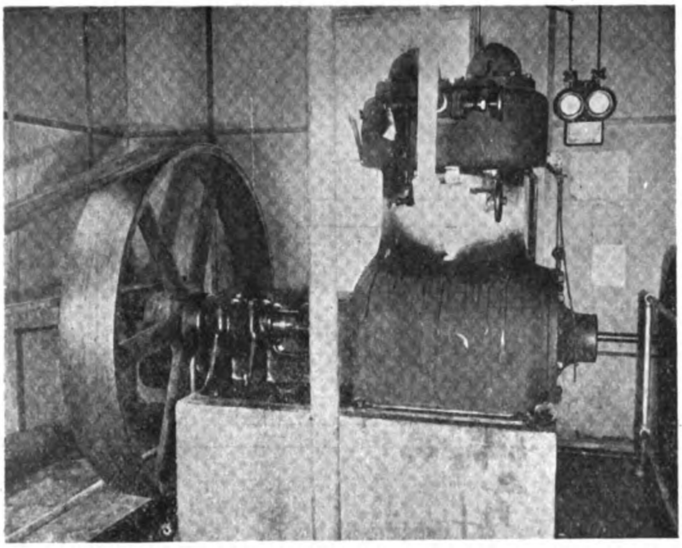
In order that the results obtained may be dependable it is essential that the entire engine should be surrounded by air at a temperature and pressure equal to those at the altitude for which the tests are to be made. This made it necessary to lay out the chamber of such a size as to accommodate the largest size engine which would ever have to be tested, as well as the necessary accessories and auxiliary apparatus. It was further necessary that the chamber should be sufficiently roomy to permit of an operator working around the engine between tests. It was found that this called for a space 6 ft. 2 in. in width, 15 ft. in length and 6 ft. 6 in. in height, and the chamber was accordingly made to these dimensions. In deciding upon the thickness of the walls and the form of construction to use, it had to be borne in mind that with the pressure of the air within the chamber reduced to one-third of atmospheric, there would be a very strong pressure tending to crush the walls in, besides which it was of course necessary to insure airtightness. The walls were accordingly made of reinforced concrete, 1 ft. thick, the reinforcements consisting of ¾-in. steel bars. There are two entrances to the chamber, on opposite sides, each 4 ft. by 6 ft. 6 in. These are closed by doors made up of 2 x 7-in. oak beams spaced 7 in. between centers and are covered on the outside with ½-in. soft wood boards, over which there is a covering of airproof roofing paper. These doors are swung on hinges and are fitted with heavy rubber gaskets to insure an airtight joint. In designing the doors the possibility of an explosion in the chamber was kept in mind. The oak beams form a sort of grid which is covered by the thin soft-wood boards on the outside, and if an explosion should take place within the chamber these boards would be torn from their framework, thus preventing injury to the walls of the chamber. Each door contains a small window through which the engine can be observed while under test. In order to reduce the transmission of heat, the walls of the chamber are provided with a cork lining on the inside and to minimize air leakage they are painted with heavy asphalt paint on the outside.

The engine test stand is located at one end of the altitude chamber and the cooling coils occupy the other end. It has already been stated that all of the engine controls as well as connections to pressure gages, thermometers, etc., are carried through the walls of the chamber. These rods, pipes, etc., must be carried through the walls in such a manner that there can be no air leakage through the openings. To this end each hole is closed by a flange and gasket. This applies also to the larger pipe connections, such as the inlet pipe to the carbureter, the exhaust pipe from the engine and the ammonia pipes to and from the cooling coils.

In designing the altitude laboratory the aim was not only to duplicate as far as possible the conditions of atmospheric pressure and temperature encountered at high altitudes, but also those of the nonrigid engine support furnished by the airplane fuselage. A form of engine support was designed which permits of adjusting the limits of engine vibration in both the vertical and transverse planes and around the three principal axes of the engine. Of course, no reliable data were at hand as to what the amplitudes of vibration in these planes and around these axes amount to in actual flight, so an estimate had to be made, and officials of the Bureau believe that the actual conditions of engine support on an airplane have been very closely duplicated. The engine support may be briefly described as follows: Two 2 x 6-in. oak beams, 6 ft. 3 in. long, are secured to the flooring at their ends. To these are bolted two supplementary beams, of 2 x 4 in. cross section and of a length differing with the engine under test. Where the supplementary beams are bolted to the other beams thin separating blocks are inserted between them. Means in the form of yokes are provided to prevent twisting of the individual beams. While the oak beams forming the base of the engine support were described as of 2 x 6-in. section, this section can be varied, and in this way a change in the vertical and lateral stiffness of the support can be effected. To vary the stiffness of the support as regards rocking motion around the axis of the crankshaft, a third beam of suitable dimensions can be rigidly secured to the yoke rods if desired. This, however, has not proved necessary.

Duplicating High-Altitude Engine Operation

In order to fully duplicate the conditions of engine operation at high altitudes with respect to temperature, it is not sufficient that the air within the test chamber should be cooled to the required degree, but the air drawn into the carbureter must also be reduced in temperature. To produce this refrigerating effect, a two-cylinder, 9 x 9-in. vertical ammonia compressor, having a refrigerating capacity of 25 tons in 24 hours, is installed at one end of the building. This compressor is belt-driven from



Refrigerating machine of altitude laboratory

a 50-hp. electric motor. Next to the compressor is located the ammonia condenser, the plant operating on what is known as the direct expansion principle.

While a single compressor and one condenser handle all of the ammonia used in the refrigerating operation, two sets of cooling coils have to be provided, of course. In addition to the cooling coils within the altitude chamber there are coils for cooling the carbureter air, which are located on top of the altitude chamber. These coils consist of 2000 ft. of 1¼-in. pipe, and are enclosed in a box with 4-in. sawdust insulation. The air, in passing through this box, follows an undulating path, which gives it a better chance to give up its heat to the cooling coils, and from the box the air passes to the inlet pipe connection in the altitude chamber wall through an insulated pipe in which there is a control valve. An air meter is incorporated in the line between this valve and the carbureter.

Five Fans Maintain Air Circulation in Chamber

The other cooling coil, that within the altitude chamber itself, contains 800 ft. of 1¼-in. piping. To maintain a strong circulation of air within the altitude chamber five motor-driven fans are installed, of which four force the air directly over the cooling coils, while the fifth may be used to maintain a strong circulation of air over the engine. The cooling capacity of the coils is such that the temperature of the air entering the carbureter may be reduced to that corresponding to an altitude of 30,000 ft. The air in the chamber cannot be maintained as cold or thin, but can be reduced to below the freezing point with an engine in operation.

However, the refrigerating plant does not afford any means for quickly and accurately controlling the temperature of the air. So, in order to permit a close temperature regulation of the air admitted to the carbureter, this air is passed through a series of electrically heated grids, by means of which its temperature can be raised again. The amount of heat imparted to the air by these grids can be accurately controlled by switches.

Some difficulty has been experienced in the past from condensation of moisture which entered the air after it had been refrigerated, and which occasionally choked the carbureter inlet and the valves. In the new installation it is hoped to overcome this difficulty by passing the air, on its way from the refrigerator to the carbureter, through a settling chamber, through which it will move so sluggishly that practically all of the snow will get a chance to settle.

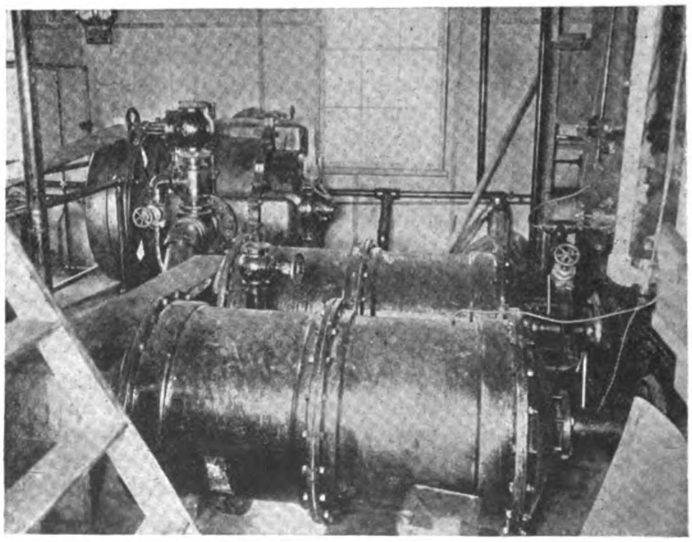
When an engine of several hundred horsepower is being operated at full load in a small closed chamber a great amount of heat is necessarily given off to the surrounding air. In order to reduce to a minimum the heat thus given off to the air within the chamber, the exhaust pipes are water-jacketed. Water is also mixed with the exhaust products in the exhaust pipes, with the object of reducing their volume and thus making it easier to handle them. Just outside the altitude chamber are located two auxiliary exhaust tanks, into which the exhaust products are discharged through two 5-in. pipes. The water condenses in these tanks and is drained off, while the non-condensing gases pass to the exhauster.

Exhausting Into Vacuum

There is one other condition besides those already mentioned which must be fulfilled in order to closely simulate engine operation at high altitudes, and that is that the engine must exhaust into a rarefied atmosphere. It is this condition which makes necessary the use of exhaust tanks. The two auxiliary exhaust tanks are connected to the 6-in. main of the exhaust pump, to which the altitude chamber is also connected by a 3-in. pipe. Hence the pressure within the auxiliary exhaust tanks is at all times substantially the same as that within the altitude chamber. There is a regulating valve on the main, close to the exhaust pump, opening the main to the outside air, by which means the degree of vacuum can be easily and accurately adjusted without varying the speed of the pump.

The exhaust pump used is driven by a belt from a 75-hp. direct-current electric motor, and has a rated capacity of 1500 cu. ft. per minute, with a 12-in. vacuum when running at 300 r.p.m.

All of the gages and engine controls are mounted on two instrument boards at one corner of the altitude chamber. These boards are so arranged that one man can control the operation of the engine and at the same time conveniently read all the gages and other instruments. Following is a list of the instruments on these boards: Five venturi gages for carbureter air inlet, gasoline supply line, jacket water, exhaust cooling water and oil-cooling water respectively. Eight pressure gages, for carbureter float chamber pressure, exhaust back pressure, carbureter choke pressure, average pres-



Exhaust pump and exhaust separator tanks

sure in exhaust manifold, difference between carbureter air venturi and chamber pressures, average pressure in inlet manifold above carbureter choke, difference in pressure between entrance to carbureter and chamber, and difference between exhaust pressure and pressure within chamber respectively; also a barometer, auxiliary barometer, thermometer and indicator showing fluctuation of chamber pressure. In addition to the instruments here enumerated, which may be regarded as part of the permanent laboratory equipment, any gages or indicators forming part of the equipment of the engine under test are also mounted on the instrument boards, as well as an ignition switch and a tachometer.

Measuring Torque

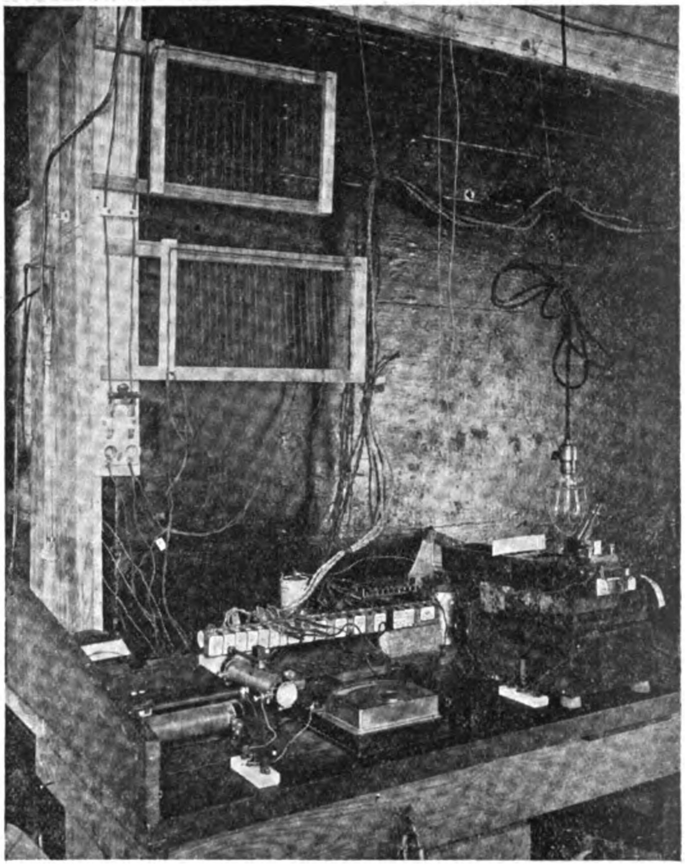
The dynamometer, which is of Sprague make, and of 300 hp. capacity, is of a type that has already been described in AUTOMOTIVE INDUSTRIES. Ordinarily, the torque is measured by means of weights placed on a scale on which rests the torque arm, secured to the field frame of the dynamometer. In addition there is a spring balance which is interposed between the scale beam and the torque arm of the dynamometer, this latter being handy for taking torque readings when no great accuracy is required. The energy absorbed by the dynamometer is dissipated in resistance grids placed outside of the building, or it may be turned into the regular power circuits of the Bureau of Standards. A hydraulic brake is mounted coaxially with the electric dynamometer, and may be coupled to it when it is desired to test engines of greater power than the capacity of the electric dynamometer. The valve for controlling the hydraulic dynamometer is placed close to the switchboard from which the electric dynamometer is controlled.

Duplicate means are provided for measuring the amount of air entering the carbureter. The first consists of what is known as a Thomas meter, an electrical device by means of which the air is heated and the temperature of the air taken before and after passing the heating element. Then from the amount of heat energy imparted to the air, as calculated from the voltage and current consumption of the heating element, the rise in temperature of the air as obtained from thermocouples placed in front and behind the heating element, and the known specific heat of air, the amount of air passing in unit time can be calculated. Changes in the amount of air flow can be compensated for by a change in the electrical energy supply to the heating element or grid, and the temperature rise thus maintained constant. The other means for measuring the amount of air passing to the carbureter consists of a venturi meter, comprising the usual form of venturi tube with connections leading to the instrument board.

Thermocouples Measure Temperature

Temperature measurements are made practically exclusively by means of thermocouples, of which no less than twelve are installed for measuring the following temperatures: Oil-cooling water, carbureter air at entrance to venturi meter, jacket water at inlet, jacket water at outlet, exhaust cooling water at inlet, exhaust cooling water at outlet, altitude chamber temperature, oil temperature at engine inlet, oil temperature at engine outlet, carbureter air between carbureter and air horn, inlet manifold and gasoline.

The thermocouples, of course, are located within the altitude chamber, while the switches and potentiometer of the temperature measuring system are mounted on a board on the side wall of the chamber. In order



Temperature measuring equipment in altitude laboratory

to obviate or minimize the effect of engine vibration on the galvanometer the latter is swung in a cradle mounted on a concrete pier.

Alternate methods are also provided for measuring the fuel consumed by the engine during a test run. One of these consists in the use of a calibrated volume tank, the other in the use of a pair of tanks mounted on platform scales. The first method is used when it is desired to determine the volume of fuel consumed, the latter when the weight is desired. The weighing tanks are most suitable for use in making a continuous test, as one of the tanks may be filled while the other is being emptied. This arrangement is also found very convenient when making a comparison of different grades of fuel. The two tanks are then filled with a standard fuel and with the fuel to be tested respectively, the engine is first run on the standard fuel, after which it is switched onto the tank containing the fuel under test, and after the run has been made on this fuel it is switched back to the tank containing the standard fuel. For the main fuel supply there are underground tanks, while the measuring tanks are located on a platform adjacent to the altitude chamber.

The new altitude chamber now under construction will be a double one, and will differ from the original one in several respects. Instead of placing the refrigerating coil at one end of the chamber it is placed under the ceiling, which allows more space for working around the engine. The two chambers are placed adjacent to each other, and can be brought into communication by opening the two doors at the ends of the communicating passage between them. This permits of testing engines of very much greater output than were contemplated when the original chamber was designed, as both exhaust pumps and both cooling coils can be operated with only a single engine under test.

Benevolent Enterprises and High Wages Offer No Solution of Labor Problem

By Harry Tipper

THE quotation below, taken from the *New York Times* of Friday, Feb. 28, concerning the strike of taxicab chauffeurs, has been called to the attention of the writer with the request that he comment upon this case:

> The company has had at all times very radical views with regard to the rights of labor, and it has always paid higher wages and given better working conditions than any other enterprise of a similar character in the city. In order to avoid any injustice, the drivers, encouraged by us, formed their own association, and it was agreed that only members of same could be employed by the company, making it thereby a closed shop in the best acceptance of the term. In addition to this the association collected $1 a month from each member, and had benevolent features covering sickness and death.
>
> In order to increase the association funds the company itself has donated regularly 25 cents for each dollar subscribed by the drivers. It elects every six months, by secret ballot, its own officers, and it has been a rule of the company that, when a driver was charged with a violation of the company's rules, he was tried before the association committee and representative officers of the company, and a final appeal to the president has always been allowed.
>
> It has unfortunately worked out in practice that this association, created with the best and fairest motives in the world, has failed in its mission, and the elected representatives of the drivers do not, for reasons best known to themselves, assist in arriving at any just and satisfactory verdict on any particular case, but constitute themselves purely and simply, no matter if they know the man before them guilty, counsel for the defense. It has come to such a pass that if a man, after a full and patient hearing, is dismissed from the service a strike is immediately threatened.

There have been several quotations at various times where manufacturers, and other men who are interested in the study of labor problems, have asked for comment upon cases similar to the above, where they allege that the fair and even generous treatment of the employees by employers has not sufficed to institute a stable labor condition and that the demands of the men in the face of such treatment have been manifestly unfair.

It is obvious that this is the case viewed from one standpoint, although conversation with the leaders of the men in most of these cases would indicate that they are not aware of their unfairness, and that they have considered the course of events justify it.

It has been pointed out in a number of these articles, however, that labor organizations have been concerned with a growth of control in the government of their own conditions of work, and as their power has grown they have attempted to seize more and more of this control. It has also been pointed out that at the beginning of the factory system, which arose coincident with the industrial revolution, the employer absolutely controlled all the conditions of work and the employee had no voice at all, even to the slightest degree, in his own affairs. From that time the employer has been concerned with retaining as much as possible of his former control, giving up a point here and there only as circumstances necessitated it.

At no time in the history of the matter, except in a few individual cases, has there been any attempt at agreement, or any desire to arrive at a common point of view on either side, and, in consequence, what may appear to the manufacturer to be fair and even generous treatment of his employees may be regarded by the employees as a merely additional protective measure, or an attempt to fasten the control still more firmly in his own hands.

Labor Takes Improved Conditions for Granted

This is the case to such a degree that no endeavors to improve the housing, the welfare, or the sanitary conditions or to take a benevolent interest in the surroundings of the employees have been of any value in materially altering the labor point of view. It does not appear to be understood by the manufacturer that in the tenets of the labor organization good housing conditions, comfortable living, sanitation and education and a reasonable opportunity for enjoyment are laid down as the rights of the worker. They are not conceded as generosity on the part of the employer but they are demanded by the worker as rights of which he has been too long deprived, and which he is justified in securing and assuring to himself no matter at what cost. It is, however, a part of the creed of the labor organization that the worker should exercise complete control of his working conditions, and this again is demanded by the worker as a right of which he has been deprived and not as a concession which he desires.

In effect, all that the company has done in the case of this chauffeur strike was to create within its own organization a labor union of its own employees to take the place of the general labor union to which the chauffeurs might belong. The encouragement which they have given in the formation of a benevolent association among their men for sickness and death benefits is of no more importance than similar associations in the general labor bodies. The payment of higher wages and even the donation of a certain amount of company funds for this benevolent enterprise are not, in themselves, incentives or a closer co-operation between the employer and the employees, and what is more, a closer study of the history of labor troubles would have informed the company that such benefits to their employees would not in themselves provide any solution for their labor troubles.

To organize employees into a labor organization does not improve their loyalty to the concern. Neither does

it provide any basis for clearing away the suspicions which have been created by the divergent views and traditions, and it does not in the least remove the desire of the worker to exercise a more complete control over his working conditions.

Capital's Disappointment Due to Misunderstanding

It is to be noted that the company has expressed its disappointment at the ungratefulness of the worker, but that expression of disappointment can be attributed to nothing else than a lack of knowledge of the employee's point of view and the history of his organization growth.

An impartial study of the whole development of labor organization, of the history of strikes, both general and individual, would have shown that the improvement of labor conditions from decade to decade did not mitigate the severity of the labor demands in the slightest degree, but only added force to these demands by virtue of the increased strength of the organization.

It is not the change in the physical conditions of labor, nor the payment of higher wages, nor even a degree of paternal interest in the employees' welfare which will have any bearing in the settlement of labor difficulties; for the reason that they simply serve to emphasize the distinction between capital and labor and, therefore, widen the split between employer and employee. They do nothing to clear away the suspicion, the opposing ideas, the misunderstanding which exists on both sides. It is not by such means that the worker and the employer can be drawn together and present a unified organization, working for the common purposes of more efficient production and distribution.

Where this organization has failed to produce harmonious relations between itself and the chauffeurs has been in its failure to recognize the fundamental fact that human unity depends upon a common responsibility, commonly shared.

It is true that the character and class of workers employed in such a company, being as a rule less intelligent than the skilled mechanic and not so well informed, can be dealt with only when greater care and ingenuity are exercised in the formation of the organization, and in the determination of their responsibility in connection with it. This difficulty, however, does not alter the necessities of the case. It merely increases the demand upon the executives, by requiring of them a greater measure of wisdom in their operations, and a much greater degree of patience in working out organization changes so that they have time to go into effect.

It is obvious that where workers are of a less stable character, belonging to the rougher elements, and without the general information which is to be found among the skilled mechanics and similar classes, it requires a great deal more patience and study, and a great deal more time to work out organization changes to the point where suspicion and misunderstanding have been cleared away and confidence has been established.

Wanted—The Labor Point of View

In any case the time for complaint has gone by. Constant reiteration of the fact that the workers' demands are unjust will not improve the situation. Complaint about the attitude of the worker is not only ineffectual but foolish. It is like any other criticism which does not offer any hope of reconstruction. The newspapers carry their news of strikes in different countries; of industrial conferences under governmental auspices in Great Britain; of proposals for the same thing in this country, the breakdown of the industrial system in European countries and of the enforcement of demands by workers which involve political changes.

These things all speak for themselves. They show the necessity for the consideration of the labor question and the consideration of some organization which will offer hope of harmonious relations without the violent overturn that is growing in some parts of the world, or without the extreme political changes which are advocated by large and powerful bodies even in this country.

This necessity for consideration, if the employer of to-day is to find a solution which will permit him to go ahead with his production work, goes right back to the ceaseless human demand for a larger share of responsibility in the government of its own destinies. This demand has been the source of political changes which have given an entirely new aspect to government in the last three hundred years. It has been transferred from political to industrial government, so that the demand of the worker to-day is for more control of his working conditions and more effective political action in respect of his social necessities. This demand will continue to grow unless the manufacturer meets it by arranging voluntarily to follow the action of some of the individual organizations where arrangements have been made to include the worker, through properly organized systems, in the discussions and decisions in regard to matters affecting his working conditions, making him responsible equally with the employer for such conditions and giving him an opportunity to share in some measure the responsibilities and the rewards of the organization.

Responsibility and Confidence Demanded by Workers

It is not enough to pay high wages, and it is not enough to invite the worker to share in the decisions affecting his conditions. Responsibility must be given, and the reward for that responsibility must also be included. The most successful operations of this kind have included both, and it is significant that the comment of the workers in these individual organizations has continually opened up with the statement that this organization was "on the square," or "on the level," or some similar expression designating the removal of suspicion.

The most difficult thing to establish and the one thing most necessary in the development of an orderly industrial organization is the demonstration among the workers of the fairness of the company's policy and operations, and it constitutes in the minds of the workers the most important basis for satisfaction, as evidenced by the fact that this point is always brought out by the workers as the first and most important accomplishment.

This necessity for clearing away suspicion and establishing confidence demands a great deal of understanding on the part of the executives or representatives of the employers who have the matter in hand. It demands a study of the reasons for the suspicion, of the ideas which permeate the worker's mind as to what he ought to have and what his rights in the case are. It demands a knowledge of the strength and weakness of the labor movement, and an understanding of the workers which should be keener than any understanding they themselves possess.

The ignorance of labor organization movement, its history and its development and the reasons for its present tendencies which exist among employers, is one of the greatest barriers to any solution of the labor problem which exists to-day. The tendency to regard it in the abstract, to view it entirely from the prejudice of the individual experience, from impressions received through reading more or less inaccurate propaganda, and from the activity of extremists make it difficult to establish any organization methods which will be successful. The attitude toward the matter is then determined by such a background.

HORSELESS AGE SUBSCRIBERS
Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation. Address 239 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries-The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

The Consulting Engineer

THERE is need in this country for a broader and more frequent use of the consulting engineer. It is too frequently the case in the automotive industry that a plant does not call in a consulting engineer until it is confronted by some knotty problem in production or design.

It is rare that the consulting engineer is called in to help paint the general picture of what a new model shall be.

The consulting engineer fulfills many requirements in assisting to help solve immediate problems, but this is only one of the ways in which he should be utilized.

The consulting engineer should have at his fingers' ends the best practice used to meet specific problems in manufacture and design, and also he should have a vision which can look into the future clearly enough to ascertain the lines of development and to note in which way the trend lies.

The plant engineer has his mind so closely wound up in the problems of his own plant that he does not often have the opportunity to acquire the broad vision of the fields which lie within the scope of the consulting engineer. The plant engineer is generally largely concerned with the solution of detail problems, which, while of paramount importance, occupy so much of his time that his opinions should be balanced with those of a well-informed consulting authority.

It is ridiculously narrow for the plant engineer to feel himself slighted if a consulting engineer is brought in. In other professions than the engineering it is common practice to call in consulting authorities. The family physician or general practitioner will always do so when confronted with extraordinary cases.

The small expense required to call in the services of a good consulting engineer is slight indeed when compared with the expense which could be caused by some part going wrong on a big production run. The consulting engineer should be fortified with a thorough knowledge of the weakness and strength of every type of construction. He should know the problems of maintenance which will be involved in any particular kind of products, and he should be able to help solve these problems in a broad way.

Now that the war is over it is realized more than ever that we must improve our products if we are to get a firm grip on the world's market. It must cease to be a question of what we can get by with, but a question of what is best practice to meet a given condition.

Services Should Be Invaluable

The services of a consulting engineer in assisting in the planning of new models along these lines would be invaluable. The consulting engineer should know the requirements of the particular field into which the product is going, and by knowing these he should be able to tell in advance what the problems of service are going to be so that these can be foreseen in laying out the designs, with the result that instead of having to make expensive replacements and having the user always confronted with repair bills, the service will be built into the manufactured article in such a way that necessity for repairs and bills for repair parts will be kept to a minimum.

A big manufacturing organization should not attempt to produce a new model without going outside its organization to call in the services of a broad-minded consulting engineer who is well versed in the particular fields in which the factory is going to enter.

The remark, "A man who turns his key in his laboratory door locks out much more than he locks in," is true. After a rough outline of the future job, no one is better fitted to give advice regarding the method of procedure in manufacture and in the determination of important points than the consulting engineer who has made a study of the field, who knows engineering practice, and who at the same time knows the service requirements and knows the points which should be avoided in that particular type of product.

Tractor Merchandising

ONE of the questions agitating the tractor industry at the present time is that concerning the class of dealers through which farm tractors are to be distributed. There are two main classes from which tractor dealers could be quickly recruited in considerable numbers, namely, the implement dealers and the automobile dealers.

Before going into the respective qualifications of the two classes for carrying on this business it should be pointed out that many of the present automobile dealers in the farming districts are now or were formerly implement dealers. They recognized the opportunity offered by the development of the automobile into a serviceable vehicle and took the necessary steps to profit by it.

On casual reflection it would seem as though the tractor business should fall to the implement dealer who already has business relations with the farmers and sells them all the necessary apparatus for working their farms. There are two reasons, however, which explain why the implement dealer has not proven very successful in selling tractors.

In the first place he is not a very aggressive merchandiser. He is an order-taker rather than a salesman and in competition with the forceful methods which have been developed in some of the newer industries he does not stand a very good chance.

Secondly, the implement man does not thoroughly understand the gas engine and its maintenance and has no organization capable of giving the service that is required in order to keep the tractor in good working condition without costly and exasperating lay-ups during the working season. It cannot be denied that there have been enterprising men in the implement trade in the past, fully capable of learning the tractor business and of organizing the necessary service force. But most of these were attracted by the automobile business at an earlier date, and those who still remain are for the most part of the conservatively inclined class.

Another angle to the problem of tractor distribution is that tractors and tractor implements must be sold by the same parties. Practically every sale of a new tractor involves the sale of a plow. Other implements specially suited for operation by tractors are rapidly being developed and eventually the business in tractor implements may exceed that in tractors themselves. The question then comes up whether the entire implement business in any locality is to be combined with the tractor business or only the tractor implement business.

One of the leading tractor and implement manufacturers recently made the statement that in his opinion the solution of the problem would be that tractor implements would be handled by the tractor dealer and horse implements by the hardware dealer. Evidently his inference was that the hardware dealer and hardware-implement dealer were not suitable material from which to recruit tractor dealers.

A New Era for the Dirigible

IN warfare the dirigible has proven a less formidable weapon than the airplane, but this is largely due to its vulnerability to attack because of its great bulk and the highly inflammable nature of the gases with which it is filled.

That there are great possibilities in the dirigible airship was also proven during the war, best of all, perhaps, by a Zeppelin which was sent from Bulgaria to relieve the hard-pressed forces in German East Africa with 25 tons of medicines and munitions. It reached its destination and upon learning that the German forces had surrendered returned to its base without even having landed. This round trip is of greater length than the distance across the Atlantic Ocean at the narrowest part.

In considering the dirigible for commercial purposes, its vulnerability to enemy attack is no longer a factor, but there remains that other great danger factor, the highly inflammable nature of the hydrogen gas with which it is filled. This is now in fair way also of being eliminated, for means have been found of producing on a commercial scale an inert gas of low specific gravity, which has hitherto been considered one of the rare elements. Hydrogen has been almost universally used, notwithstanding its fire danger, because of its light weight and consequent great buoyancy. It weighs only one-sixteenth as much as atmospheric air.

The new gas which it is proposed to use as a substitute for hydrogen is helium, which is found in very small quantities in the air. It has been discovered that this gas is also a constituent of certain natural gases, and the United States Bureau of Mines has been studying means for extracting it from these gases and obtaining it in sufficiently pure form on a commercial scale. These efforts, it seems, have been crowned with success. A plant has already been installed capable of producing 50,000 cu. ft. of the gas per day and the cost is said to be no more than 10 cents a cubic foot, which cannot be so very far removed from the cost of hydrogen.

Although helium has a specific gravity of nearly 4, as compared with hydrogen, the standard for gaseous specific gravity figures, its buoyancy is not so very much less, the buoyancies of the two gases being in the ratio of 15 to 12. The number of Zeppelins that were burned during the war may give a somewhat exaggerated idea of the natural fire risk of a hydrogen-filled bag, for the reason that many of the explosions were due to enemy fire; still, the proximity of a number of internal combustion engines to such enormous quantities of highly inflammable gas constitutes a very serious risk which would have been a great drawback to commercial development. With this risk eliminated the lighter-than-air type of machine may still come into its own in the commercial field.

Latest News of the

Contract Validating Bill Signed

Forms and Instructions for Immediate Payments Now Being Distributed

WASHINGTON, March 3—President Wilson last night signed the bill validating so-called informal war contracts which had been made by telegraph, telephone or in other ways not "legally" executed. Payment of these contracts had been refused by the Treasury and the new bill therefore validates them and authorizes payment. The contracts that came under the informal classification totaled $2,000,000,000, of which more than $300,000,000 were held by automotive manufacturers. The delay in paying these was said to be one of the chief causes of unemployment, as many manufacturers were unable to secure funds to proceed with peace time work.

The bill as signed following numerous amendments and revisions in Congress provides the Secretary of War power to authorize payment, allows for appeals from his decision to the Court of Claims, insures that sub-contractors be protected by direct investigation by the War Department of all prime contractor's contracts, and limits the filing of claims under the act of June 30, 1919. The Secretary of War is also ordered to report all payments made under the act at the next session after June 30, 1919.

Those contracts which were properly executed prior to the signing of the bill will come under class A and the claims will be forwarded directly to the various claim boards handling the respective products called for by the contracts. For example, an ordnance contract, after being prepared for claim in quadruplicate form, will be sent directly to the Ordnance Claims Board, where it will receive an identifying number, be reduced to certificate form embodying the important details and the award made. No awards will be paid until the approval and acceptance of the claimant is secured.

In those instances where the Government officials decide it is best to make direct payments to the sub-contractors who are interested in the contract of a prime contractor this will be done.

Those contracts which have not been reduced to the proper legal form and which are still merely in the form of a telegram or verbal will come under class B. Special blank forms are provided for reducing these to concrete form. All class B contracts will come before the Board of Contract Adjustments which will investigate their proof of claims and refer them to the Bureau Claims Board, Ordnance, Air Service or Quartermaster, as the case may be.

In event a claiment is not satisfied with the award of the Bureau Claims Board he may appeal to the Board of Contract Adjustment.

To Pass on All Contracts

WASHINGTON, March 6—A Board of Contract Review of the Motors and Vehicles Division of the Office of Director of Purchases has been created and will pass on all termination agreements of formal and informal war contracts for trucks, cars, motorcycles, parts and accessories and trailers, before the agreements are submitted to the Claims Board of the Office of the Director of Purchases for final approval. The Board of Contract Review will consist of five members and the Chief of the Motors and Vehicles Division. These will be appointed by the Chief of the Motors and Vehicles Division and approved by the Director of Purchases.

Urge Road Building Program

Conflicting Views on Labor, but Not on Value of Highway Development

WASHINGTON, March 5—Conflicting views of the labor situation and unanimous approval of the value of good roads directly to the public and as a "buffer" employment for labor marked the conference held here this week by President Wilson and Cabinet members with Governors and Mayors of the United States.

Some discussion as to the best methods for reducing existing prices and for maintaining the proper equilibrium of national sentiment on the present immediate problems also took place.

The reports from the Governors or their representatives included 16 states, with a summary as follows:

Arizona—A billion pounds of copper thrown on the market recently have drugged it, with the result that 60,000 miners are working short shifts or are out of work. Buffer, or temporary work, is being rapidly designed to take care of the men, but need of a special agent from the Government to restore the morale of business men is needed.

Delaware—No soldiers who return will fail to find a job. The situation is far more serious. More than $6,000,000 to be spent on good roads.

Florida—Could use labor if it will work at a fair price. Many projects for drainage and improvements of roads contemplated.

Georgia—Conditions in labor market are generally as satisfactory as could be reason-

K. C. Show Mecca for Parts Makers

Makers of Tractor Parts Plan for Next Year's Show—Attendance Sets Record

KANSAS CITY, March 5—The closing of the Fourth National Tractor Show here this week turns the attention of tractor and parts makers ahead to next year, when the fifth tractor show will be held here. This will be larger than the present one. Next year's show is already assured and the exhibit of parts, too, will without doubt be much more extensive than this year.

At a national tractor show it is to be expected that all of the tractor makers will be present, but many were surprised at the wonderful exhibit of parts, and almost all of these were from the automobile industry, or, more accurately speaking, the automotive industry.

There were practically all of the makers of ball and roller bearings. There were the makers of magnetos, spark plugs, carbureters, piston rings, radiators, sheet metal goods, engines, bronze materials, castings, lubricants, etc. Makers of stampings were on hand, but not in such great numbers. Some of these have already brought out very light tractor wheels, pressed steel frames, etc., and are preparing to make stampings for other parts.

Exhibits Best Ever Seen

The exhibit of such parts was the best ever seen at a tractor show and was better than any seen in recent years at the New York or Chicago shows. These makers are selling their product in large quantities to the tractor maker.

One manager of a parts organization did not think it necessary to make an exhibit or to bring his engineering representative along. After making one circuit of the show and seeing what a comprehensive exhibit there was of tractor parts he at once wired his factory to send some of his engineers and also men from the sales end to study the field. He was too late for this year but was not going to lose any time.

Being held the same week as the automobile show there was a good attendance of distributers and dealers. The tractor makers have shown good business judgment in holding it this week in order to get the benefit of all of the dealers. Nearly every maker was looking for a dealer. Some placed one or two distributers and appointed a dozen or more dealers. There were many prospects for

Money Provided for Highways

President Signs Bill Appropriating $200,000,000—Total Available, $574,000,000

WASHINGTON, March 3—President Wilson has signed the Post Office Appropriation bill carrying an amendment providing for $200,000,000 to be expended in the next 3 years for road construction. This sum, together with the State appropriations which must meet the Federal funds on a dollar-for-dollar basis, will provide at least $574,000,000 for highway building before 1922. As most of the States are appropriating sums in excess of the Federal requirements, it is expected that this figure will be greatly exceeded, and, in fact, it appears that this amount may be spent during the year 1919 alone. Reports already received of State appropriations indicate $385,000,000 already available.

Employment will be given to 100,000 men for the road work, according to a statement by Secretary Houston of the Department of Agriculture Saturday before representatives of the highway departments of 27 States. The secretary said his department would give every aid to the work.

Expect Freight Rate Revision

Complaint was made by the highway commissioners that existing freight rates for road building materials are too high and hamper work. Railroad officials have promised a decision regarding lower rates within 10 days. The conference also asked that engineer regiments now building roads in France be returned at an early date and demobilized so these men could be secured for road work in this country. Secretary Houston promised to bring this matter before the War Department.

An important effect of the new bill is that it broadens the definition of a rural post road and allows the funds to be used for highways where mail may be carried at some future period as well as where it is carried at present.

The act also raises the limit of Government contribution from not to exceed $10,000 per mile to not to exceed $20,000 per mile, and further authorizes the Secretary of War to transfer to the Department of Agriculture such road building machinery and materials as are suitable and not required by the War Department.

With the $200,000,000 made available by the new law, there is not included $9,000,000 also appropriated and which will be used for roads and trails in national forests.

The original Federal Aid Road act, passed in July, 1916, appropriated $75,000,000 for the 5 years ending June 30, 1921, and $10,000,000 for forest road building. Not over $3,000,000 of this fund has been spent, due to the war, so that $82,000,000, plus $209,000,000, or a total of $294,000,000, will be available during the next few years. The act and its amendment requires the States to provide at least an equal amount on the post road work.

On page 553 is a table showing approximately what each State will receive in Federal aid under the terms of the act.

American Motors Increases Production

NEW YORK, March 5—The American Motors Corp. is planning an increase of production to take effect in 3 or 4 weeks. The company built 600 cars in 1918 and now plans an output of five a day, and ten a day when the full capacity of the plant is brought into play. A $500,000 increase in the capital has been made in order to take care of this increase. Leslie F. Smith has become general sales manager. Mr. Smith was supervisor of zones for the Maxwell company and branch manager for Willys-Overland. In 1912 he opened the Oakland branch in this city and later became general manager for ten Southern states. L. P. Rife will become works manager in charge of purchases and production. He was formerly supervisor of production at the Hudson plant in Detroit.

Cross-Ocean Flight Planned

WASHINGTON, March 3—Plans for a flight across the Atlantic are being completed by the U. S. Navy, according to continued rumors here, none of which are as yet confirmed. It is said that the navy will use the NC-I flying boat and will conduct test flights at Rockaway Point this week. This is the largest American seaplane equipped with three Liberty engines and having a capacity of 10,000 lb., and a present fuel capacity for 1200 miles.

Texas to Have Airplane Company

DALLAS, March 5—Incorporation papers of the Texas Airplane Manufacturing Co. will be filed soon. The company will have a paid-up capital stock of $1,000,000, and its purpose is to construct and operate an airplane manufacturing plant here. Lt. C. G. Taylor of Lexington, Ky., is chief promoter of the project.

Ford Will Produce $250 Car

To Withdraw Entirely from Present Company—$19,000,000 Decision Caused Move

LOS ANGELES, March 5—Henry Ford gave out an interview here to-day in which he stated he would quit the present Ford Motor Co. and bring out a $250 car. This decision, he states, was brought about by the recent court decision compelling him to divide $19,000,000 profits.

"I have decided on the new undertaking, and as matters stand I intend to go ahead with it," said Mr. Ford. "This idea developed from the recent court decision whereby I am obliged to distribute about $19,000,000 accumulated profits. The public will not suffer from this because as a result they will get a better car, a cheaper car and one more fully up to date than before or than is now in existence. The present Ford car was designed 12 years ago.

"The decision that caused me to make this move is because of my principle to have plenty of cash with which to do business. Of that $19,000,000 I have to distribute to myself about $12,000,000, but I cannot in justice to myself put that back in the business, because I have no way to oblige those who own the other portion to so employ it.

"My only recourse is to get out, design a new car which can be sold cheaply and which will be in all details up to date. We are already looking for water power sites. The car itself is well advanced, for I have been working on it while resting here in California. We shall have a plant on the coast and stations all over the country. We propose to dot the whole world with our factories because I believe that every family should have a car and this can be done.

"Our tractor factory is paying at the rate of $500,000 a month. It is capitalized at $5,000,000 and has accumulated $12,000,000 assets.

"I do not know exactly what will become of the present Ford Motor Co. The portion of it that does not belong to me cannot be sold to me; that I do know. I must do business on the basis of what I think is right. I do not like stock companies. The Ford Tractor Company stock is all held by members of the Ford family."

DETROIT, March 5—Officials of the Ford Motor Co. will neither affirm nor

Problems of Tractor Design Discussed at Kansas City S. A. E. Meeting

Difficulty of Accurate Tests and Technical Points of Construction Brought Up—Need of Scientific Research Applied to Agricultural Machinery—Standard Fuel Suggested for All Internal Combustion Engines

KANSAS CITY, March 1—The tractor meeting which the Society of Automotive Engineers arranged in connection with the Kansas City Tractor show was held in the auditorium on the top floor of the Sweeney Automobile School on Thursday afternoon and was attended by about 200. To the program of three papers originally published, there was added at the last moment a fourth paper, on "The Redesign of Farm Machinery for Tractor Work," by Prof. White, of the University of Illinois. Unfortunately two of the authors of papers could not be present to take part in the discussion.

How to Determine Drawbar Horsepower

The first paper read was on "Tractor Testing," by Prof. J. B. Davidson of the California State Agricultural College. Prof. Davidson outlined the different tests which it is desirable to make on farm tractors and said that his paper was confined to the subject of field tests.

The drawbar horsepower, which is determined in these field tests, is one of the important elements of the commodity sold by the tractor manufacturer, and is, therefore, worthy of careful measurement. Prof. Davidson referred to the S. A. E. horsepower rating formula and the difficulty which had been encountered in accurately determining the proper rating of tractors. This he said was largely due to the fact that there was no traction dynamometer on the market which permitted of the two-hour test called for by the rating formula. It was stated in the paper that the test horsepowers of the 42 tractors tested last summer at Salina varied from 50 to 200 per cent of the rated horsepowers. If there were a convenient method of accurately determining the actual horsepower of which a tractor is capable it would not be necessary to provide such a large reserve of power and there would be less overloading.

Further, the purchaser would not have to discount the manufacturer's rating, as he is in the habit of doing now. The proposal has been made to do away with horsepower ratings entirely, and instead to express the capacity of tractors by the number of plows they will pull. Inasmuch as the size of plow bottoms vary, and as there are great differences in the amount of power required to pull a bottom in different soils, this would be a very haphazard method.

Accuracy in Dynamometer Tests

Prof. Davidson said that two of the essentials in making a dynamometer test are accuracy and a clear record of the data obtained. A direct reading dynamometer, he explained, was almost useless, on account of the continual and wide fluctuations of the indicator hand. The author described the Hyatt dynamometer in general terms. It had been objected, he pointed out, that a spring was not suitable for measuring drawbar pull, but it was shown that some kind of elastic material was necessary in order to register this pull. The direct indicating type of instrument being unsuitable, a recording mechanism is absolutely necessary in order to obtain reliable results.

There are advantages in having tractor tests in connection with field demonstrations. When there are a large number of tractors assembled together at one point tests can be made with the least effort. However, the hurrah and excitement which usually mark these assemblies are detrimental to the conduct of the tests.

In the discussion of the paper it was pointed out that the subject of a standard rating was one of great importance to the tractor industry. Many state agricultural colleges are studying the problem and the State Legislatures are planning legislation covering the point, with the object of protecting the farmer. Therefore, if the tractor manufacturers are not careful there may soon be as many tractor rating formulas in use as there are States in the Union.

It was pointed out by Prof. White of Illinois State University that the statement that no tractor dynamometer was manufactured suitable for making two-hour dynamometer tests was incorrect. The Burr Co. of Champaign, Ill., had been manufacturing railroad dynamometers for 15 years and had recently developed a dynamometer suitable for tractor work which had been used in plowing tests at the university. It was based on the hydrostatic principle, had a range of 1 to 10,000 lb., and was fitted with a recording mechanism. It was also brought out in the discussion that the National Vehicle and Implement Association had been considering the subject of tractor ratings.

A Standard Fuel for All Engines

The second paper was that on "The Fuel Situation," by Dr. Joseph E. Pogue of the United States Fuel Administration. Dr. Pogue covered substantially the same ground as in the paper which he read at the S. A. E. annual meeting in New York last month, but handled the subject more from the standpoint of the tractor manufacturer. He said that the present tendency in the tractor industry with respect to fuel appeared to him unwise. At the present time the United States has an annual production of 40,000,000 bbl. of kerosene, which sells at about one-half the price per gallon of gasoline. Seventy million barrels of gasoline are produced per year. Kerosene, however, may not always be cheaper than gasoline, as with the rapid increase in the number of tractors the demand will grow quickly, while, on the other hand, owing to the development of the so-called cracking process, the amount of kerosene derived from a certain production of crude oil will become less. Gasoline, under present conditions bringing a higher price than kerosene, the tendency naturally is to convert more and more kerosene into gasoline. This will before long result in a scarcity of kerosene.

Reverting to his remark that it would be unwise to design tractor engines for kerosene fuel, Dr. Pogue said that kerosene had been specially designed to possess wick climbing properties, which were unessential in an internal combustion engine.

The Fuel Problem

The present outlook was that both automobiles and trucks must be developed to burn heavier fuel, and Dr. Pogue suggested the advisability of designing all types of automotive apparatus to use the same kind of fuel. The tractor fuel problem does not stand alone, but will have to be solved along with the fuel problems for other types of internal combustion engines. The problem really is, whether both truck and tractor engines shall be designed to consume a heavier grade of fuel, leaving the lighter constituents of petroleum for use in passenger car engines, or whether all kinds of automotive apparatus shall use the same fuel. From one point of view at least the latter course would be preferable, as it would greatly simplify the fuel distributing problem, and result in important economies.

One other point brought out by Dr. Pogue was that the price of the fuel determines the saturation point of the country with respect to both automobiles and tractors. That is to say, if there are a certain number of farmers who can afford to operate a tractor burning a fuel costing, say, 15 cents per gallon, then the number of farmers who can afford to operate a tractor designed to run on a fuel costing 50 cents per gallon is materially smaller.

In the discussion of this paper Dr. Pogue was asked about the probable influences the resources of the country in shale oil deposits would have on the fuel situation. In the reply it was brought out that shale oils are analogous to petroleum in their chemical composition, and by distillation will yield practically all of the fractions which are now obtained from crude oil. However, the cost of obtaining these fractions from shale oil is very much greater, as the latter have to be mined, crushed and then subjected to the distillation process.

Tractor Trials in Great Britain

Shortage of 60,000 Tractors in United Kingdom—Agencies Under Car Dealers Popular

LONDON, Jan. 28—The Society of Motor Manufacturers and Traders, Ltd., which corresponds to the National Automobile Chamber of Commerce in America, has decided to hold a trial of tractors about the end of September in the Midlands. At first there were hopes that this body as representing the motor industry would be assisted by and associated with the Royal Agricultural Society of England, the premier and oldest organization of farmers and implement makers, but the latter body favored postponing the trial to next year.

It is of interest as marking the passing of the implement and tractor trade from the older order of implement dealers to the motor dealer. The step has been in preparation since the introduction of tractor plowing and cultivation on the grand scale, which was brought about by the threatened shortage of food cereals in consequence of the war's demands on ships and the losses of food ships by submarines.

Tractors and Farm Implements

The tractor and implement trade was solely in the hands of the implement dealers; and of tractors, at least of the gasoline sort, there were but a few scores where now they number hundreds, three-fourths of them being American. The implement and farm engine makers concentrated on steam plant until about three or four years before the war, when there began to be seen fewer steam engines and more oil and gasoline engines, but hardly any except steam locomotives for land work.

The result was that such equipment was hired by those whose farm lands were large enough to make it remunerative; the vast majority of farmers having no interest in it or its development, instead of horses. It is otherwise since motor dealers began to push American tractors.

Fortunately, at the outset of this branch of motor trade enterprise, the cost of imported tractors was not prohibitive, and when it did rise in consequence of war conditions, prices of crops and other factors had turned in favor of the farmers, backed by the compulsory tillage policy of the Government acting through its Food Production Department.

It happened also that the services of motor dealers were taken advantage of in this campaign, and latterly the dissemination of hundreds of Fordson tractors both increased the hold on this industry of the motor dealers as Fordson agents (most of them being also dealers in Ford cars) and widened the farmers' interest.

Officially, it was stated last year that there were nearly twenty million acres now in tillage in the United Kingdom. It has been computed that from 50,000 to 75,000 tractors are needed to maintain the vast bulk of British farms under 500 acres in arable condition.

At the moment there are probably not more than 10,000 tractors available in the United Kingdom, and so far there is no evidence of any real effort toward a home production of tractors. The Auston Co., at Birmingham, were recently reported to have fixed the price of their tractor at £200 ($1,000), but, considering that the Fordson, which has been on the market for nearly two years, is listed here at £250 ($1,250), and that the Austin has a governor and geared belt pulley, it may be doubted if the Austin or any other British tractor can be produced to sell at less than the Fordson under present market conditions in this country.

A Scottish firm has been trying out a two-cylinder tractor after the style of the older Moline. Beyond having seen the first sample on a farm land in course of testing, nothing has appeared. Prior to the big rise in transatlantic freight charges the Moline was one of the cheapest and most interesting imported tractors, hence it may be inferred that this Scottish model, if it is a success, will be priced to correspond with the Moline on the British market. The Moline appeals to British farmers, as it is light and handy, and one of the very few really single-handed tractors. The Fordson has sold here largely on price, and because of the Ford "service" associated with it, the bulk of the dealers concerned in it being also Ford car dealers.

Need of Special Tractor Implements

British farmers are not too favorable to a three-furrow tractor, and certainly they do not take kindly to the usual American 14-in. bottom with its flat turn over of the furrow. Our normal horse plow will average ¾ acre per 10-hr. day, with two horses. A two-furrow tractor, capable of averaging three acres per day, of corresponding duration, is appraised better than a more powerful machine, with a bigger output on a very much larger fuel consumption.

Many tractors here have not been improved by efforts to run them on kerosene. The International Harvester Co.'s tractors may be cited as successful on this score, but these have slow-running engines, and an adequate lay-out for water injection. The fuel drawback, however, is likely to be removed with the large increase of gasoline. In fact, at present there is more gasoline than there are engines and vehicles in which to use it.

A need found here as well as in America is a line of special implements for tractors of the sort and size referred to. The implement makers promise to supply this want, but, judging from the delay in starting on tractors themselves, the outlook is not too reassuring in that quarter.

Among implements needed is a smaller

Standardized Fuel Urged by Pogue

Speaking at S. A. E. Dinner—Two Kinds of Dealers and Three Types of Tractors

KANSAS CITY, MO., Feb. 27—The present policy of fuel for automotive apparatus is unwise in that the greatest possible fuel value is not being had from each gallon of crude, and something must be done to determine the future of this question, is the opinion of Joseph A. Pogue of the fuel administration, Washington, at the annual tractor dinner of the S. A. E. here to-night. Mr. Pogue, speaking especially to tractor men, sees two solutions to the fuel question.

1—The first is to use the entire range of petroleum products which will burn successfully in all types of internal combustion engines. It means one standardized fuel for all types of apparatus.

2—The second is to have two standard fuels, a light one for motor cars and airplanes and a heavier one for trucks and tractors.

Mr. Pogue favors the first plan. He wants one fuel because it will mean cheaper and easier merchandising, and it will also give more fuel value out of a gallon of crude. He argued for a greater splitting up of kerosene and thus greatly increasing the production of gasoline and reducing the quantity of kerosene.

J. B. Bartholomew, president of the Avery company, looks for two kinds of dealers, and two only. There will be the tractor dealer who sells tractors and all farm machinery to be used with them. The second class will be the hardware man, who will handle horse-drawn machinery and equipment. The division between motor equipment and horse equipment is becoming more defined every day.

Finley P. Mount, president of the Advance-Rumely Thresher Co., and toastmaster for the dinner at which 270 attended, looks for three kinds of tractors to round out the field of farm requirements—heavy, medium and light.

E. A. Johnson, engineer of the International Harvester Co., also spoke.

David Beecroft gave an illustrated talk on his trip over the devastated areas of France and Belgium.

S. A. E. to Visit Splitdorf

NEW YORK, March 5—The Splitdorf Electrical Co. has invited the Metropolitan Section of the S. A. E. to make an inspection trip through its plant in Newark on March 7. The company will have automobiles meet the party at the station and will entertain them at luncheon. It has requested that the number be limited to 150.

New Comet 1½-Ton Truck

DECATUR, March 1—The Comet Automobile Co. is now producing a 1½-ton truck to sell for $1,750 in place of the 1¼-ton model which sold for $1,575.

January Exports Satisfactory

New Year Augurs Well for Our Foreign Trade in Automotive Products

	Cars	Value	Trucks	Value	Parts
Jan.	2,137	$2,916,381	907	$2,375,584	$2,406,783
Dec.	1,703	2,203,027	896	2,636,689	2,191,511
			1918		
Jan.	4,325	3,841,871	1,156	3,328,870	2,665,278

WASHINGTON, March 5—Although it may not be apparent at a casual glance why our export figures are tabulated for the seemingly odd number of seven months in the tables herewith there is a reason. This reason is that the seven months in question bring the data to the commencement of the new fiscal year, commencing on July 1. As on this basis the figures coincide with the commercial year of a number of concerns engaged in the automotive industry, it is suggested that they may be peculiarly applicable for purposes of comparison.

January exports from the various ports of the United States are exceedingly satisfactory. There is an appreciable (though possibly not a really substantial) increase in cars, trucks and parts, and that this is the case argues well for our increased merchant marine. After all, the matter of available shipping when and where it is needed is of primary importance if we are to maintain our position in the world's markets. So far it has not been a matter of lack of orders, it has been simply a question of ships to transport the goods.

It is true that at the present time many ships which will be available for commercial expansion at a later date are engaged in the work of repatriating our men from overseas. Once this shipping is released (and the time does not seem far distant) there is every reason that the present automotive export figures will be increased appreciably.

It is, however, equally correct to state that much of our export trade has been simply handed to us. For some time we have had no competitors in the markets of the world. Conditions are altering rapidly, and it is up to us to retain, and improve, our position in those markets.

Weekes-Hoffman to Make Gears

SYRACUSE, N. Y., March 4—The Weekes-Hoffman Co. has completed plans to enter the gear manufacturing industry, and will shortly be turning out gears for automobiles and tractors in quantities which will necessitate the employment of 250 men in the plant on Dickerson Street. W. H. Diefendorf has severed his connection as chief engineer and a director of the New Process Gear Corp. to join the Weekes-Hoffman Co. as vice-president and general manager. J. M. Weekes is president, and A. J. Hoffman secretary and treasurer.

Air Service Club of America Formed

NEW YORK, March 4—The Air Service Club of America has been organized by army fliers to promote the social interests of aviators.

January Exports from New York

New Year Brings Big Increase in Cars, Trucks and Parts Value

NEW YORK, March 5—Exports of automotive products from this port have fluctuated throughout the past year, not so much on account of the variation in the volume of orders as on account of the limitations of shipping facilities. The real position has been that each month would have fully maintained its average but for restrictions brought about by lack of ships.

Latin American Trade Satisfactory

The new year starts well with increased exports in cars, trucks and parts. In January cars numbered 1047 as against 740 in December, 1918, the respective values being $1,480,832 and $1,020,126. Trucks numbered 515 in January, as compared with 430 during the previous month, and their value advanced from $1,564,293 to $1,604,418. Similarly, the value of parts was $1,189,577, as compared with $898,513 in December.

Latin American trade continues satisfactory, Argentina being our principal customer for passenger cars, but Australia and British South Africa were our largest buyers. Japan's purchases of trucks were surprisingly large and augur well for trade development.

Refinance Saxon Company; Pick Prominent Head

DETROIT, Feb. 27—It was stated today by officials of the Saxon Motor Car Corp. that Chicago, Boston and New York bankers have agreed to refinance the company to the extent of $5,000,000, and that the Saxon would start operations within 60 days. Reorganization details were completed at a meeting in Chicago Wednesday, Feb. 26. The new organization will be effected within the next 10 days. Financial men backing the project assume all Saxon liabilities, and the company will start again with a clean slate. Details of the refinancing plan cannot be announced at this time, but it is said the banking interests involved are among the largest in the country and are amply able to put the project across.

The Saxon officials deny the rumor published in New York and Boston financial dailies telling of a proposed merger with the Doble-Detroit Steam Car Corp. There will be no enlargement of the present Saxon plant this year. The present manufacturing policy will be continued, and standard Saxon models embodying many refinements will be produced.

Characteristics of Standardized Engine

(*Continued from page* 527)

An additional advantage is the fact that a valve equipped with two springs will still function, even with one spring broken or out of commission.

Force-feed lubrication is of course essential to insure a proper and efficient lubrication. A high pressure up to 80 or 90 lb. per square inch is recommended for speeds up to 3800 r.p.m. A series of gear pumps or a multiple-plunger type pump may be used. Oil leads should be of generous size, and provision for effective cooling of the oil should be made before returning it through the engine circulating system. The above oil pressure of from 80 to 90 lb. per square inch may seem unnecessarily high, but it is advisable, because the function of the oil in the bearings is not only to reduce friction to a minimum but also to disperse the heat. For that reason very large aluminum bearing caps may be used, although ordinarily a light steel forging is to be preferred.

In such a standardized engine most parts, such as cylinders, pistons, valves, connecting-rods, may be made interchangeable, thereby effecting a considerable saving in manufacture. Special bracket or hanger adapters will make the engine installation suitable to several makes of chassis.

K. C. Show Mecca for Parts

(*Continued from page* 544)

retail sales obtained which are being handed over to the dealers.

The attendance was much ahead of last year; in fact, it was beyond expectations. There were several thousand dealers and the farmers filled the place from early morning until supper time. There was little doing at night.

Every exhibitor is pleased and plans for next year are for a bigger show. The $40,000 building used this year is already being torn down. One thing is certain: Kansas City has had the national tractor show for 4 years and is not going to let it slip away. Minneapolis is being watched with anxious eye, but there is room for two or three.

It is more or less of a mistake not to have several larger territorial tractor shows. They could not all be national shows but they would be most valuable to dealers and farmers.

Vahan Products Enters Cleveland

CLEVELAND, March 1—The Vahan Products Co., a new corporation, has purchased from the Western Machine Products Co. its property on the northwest corner of East Seventy-third Street and St. Clair Avenue N. W. The land, building and equipment will cost more than $350,000, and the new company will employ at the start from 300 to 400 men. Automatic screw machine products will be manufactured. The Western Machine Products Co. during the war, manufactured airplane parts for Rolls-Royce. S. S. Shields is president of the Vahan Products Co.; L. H. Mesker, vice-president; A. W. Leuke, treasurer, and L. M. Lucius, secretary. Operations in the new plant will commence at once.

American Plane Establishes New Record for Speed

WASHINGTON, March 1—New records for speed and climbing were established yesterday by an American designed and built airplane, according to announcement by the War Department of the results of preliminary tests of a machine constructed at Ithaca, N. Y.

In the tests the plane attained an officially timed speed of 163 2-3 m.p.h., or 2.72 miles per minute, and climbed 10,000 ft. in 4 min. 52 sec. The best previous climbing performance was 10,000 ft. in a little more than 6 minutes.

The new plane, except for diminished wing span, was described as not widely different from the common type of single-seated biplane. The wings measure only 26 ft., or 6 ft. less than the small Spad machine. The motive power is a 300 hp. Hispano-Suiza engine. The machine, full loaded, weighs 2050 lb. and has a full speed operating period of three hours.

The quickest trip between Washington and New York in a mail plane with a 150 hp. engine was also made yesterday when Aviator Biffle took mail from College Park to Belmont Park, a distance of 218 miles, in 2 hrs. 2 min., flying time. The speed between Washington and Philadelphia was 97½ m.p.h. and between Philadelphia and New York 125½ m.p.h.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

New Twin City Tractor of Backbone Type

MINNEAPOLIS, March 3—A new tractor, known as the Twin City 12-20, has just been brought out by the Minneapolis Steel & Machinery Co. The engine is of the 16-valve type, all valves being located in the cylinder heads. Samples of the machine have been in the hands of farmers for some time, but its public announcement was reserved for the New York and Kansas City shows.

It is claimed for the double valve construction that it permits the cylinders of clearing themselves better of burnt gases, thus insuring a higher volumetic efficiency and increased power. The new tractor is designed to operate on kerosene, on which fuel its engine is claimed to develop 35 hp., while on gasoline it develops 40 hp. at 1000 r.p.m.

Other features include a pressure feed lubrication system, water circulation controlled by a thermostatic valve, a sealed and enclosed governor and a backbone type of frame. A full technical description of this machine will be published in an early issue of AUTOMOTIVE INDUSTRIES.

Sperry Wants Enemy Gyroscope Patents

WASHINGTON, March 1—The Sperry Gyroscope Co., Brooklyn, has asked the Federal Trade Commission for licenses to use nine alleged enemy patents covering the manufacture of gyroscopic apparatus. The commission is considering the application.

Gramm-Bernstein Trucks to Be Sold Direct

LIMA, OHIO, March 1—The Gramm-Bernstein Motor Truck Co., which until recently sold its truck in the Eastern territory through the Gramm-Bernstein Sales Corp., with offices in New York, Philadelphia and Akron, will direct sales and service hereafter from the factory.

Hudson Peace Schedule

DETROIT, March 1—The Hudson Motor Car Co. will devote the entire plant erected for the manufacture of shells during the war to the production of its new Essex. It is estimated that it will make 20,000 Essex cars this year. The same number of Hudson Super-Sixes will be turned out and by June it is estimated that the monthly output of Super-Sixes will be about 2000. At a recent meeting of the Board of Directors the expenditure of $1,000,000 was authorized for additional machinery and manufacturing facilities.

Reo Shipping 74 Cars Daily

LANSING, March 5—The Reo Motor Car Co. is making a number of shop changes and otherwise getting back into peace production. Although not completely adjusted as yet to domestic business, the company is shipping an average of 74 vehicles a day.

Hawkins Denies Merger Rumors

DETROIT, Feb. 27—Norval A. Hawkins, former sales manager of the Ford Motor Co., denies all rumors of a proposed truck and tractor combine which he is said to be forming.

Republic Purchase Story Unfounded

DETROIT, Feb. 27—W. C. Durant, president of General Motors Corp., which is said to have recently purchased the Republic Motor Truck Co., Alma, positively denies that such a deal has taken place.

To Make English Dunlop Tires in Canada

TORONTO, March 3—The Dunlop Tire & Rubber Goods Co. has obtained rights to the tire-making methods and formulae of the English company and will have access to the large rubber plantations owned by the parent concern in England.

First Wolverine Tractor Completed

SAGINAW, MICH., March 1—The Wolverine Tractor Co., newly organized, has built its first tractor, and within 30 days quantity production will start. One thousand machines will be built during 1919. Within 60 days 75 men will be working in the plant, which will occupy about half of the old Bransfield-Billings factory. W. E. Wood, Detroit, is president of the new concern, and W. H. Wagenhals superintendent.

Champion Ignition Co. to Produce 120,000 Plugs Daily

FLINT, March 1—The Champion Ignition Co. is now producing 80,000 plugs a day, but will run this production up to the 100,000 mark in March, and 120,000 daily by early summer. During the war the company was busy on plugs for the Liberty and other aircraft engines, producing 40,000 daily for the Government.

1000 Trenam Tractors Planned for 1919

STEVENS POINT, March 4—The Trenam Tractor Co. at its annual meeting made provision for the beginning of quantity production of the Trenam tractor. It is hoped to manufacture more than 1000 during 1919. Since establishing its plant, the Trenam company has devoted much of its capacity to the production of castings for other companies, at the same time developing its tractor design, which now is ready for the market. J. J. Trenam of Milwaukee, who designed the tractor, was re-elected president and general manager of the company.

Six-Cylinder Maibohm Half-Ton Business Car

RACINE, March 4—A business car with a capacity of ½-ton, selling for $1,290, is being delivered to dealers by the Maibohm Motors Co. It is powered with a six-cylinder Falls engine with cylinders 3⅛ x 4¼ in. The valves, which are in the head, are adjustable, and the cooling is by thermo-syphon system, using a Perfex radiator. Starting and lighting is by a Wagner 6-volt, two-unit system with a Bendix drive starter and generator driven through helical gears in the gearcase. The Willard battery is carried in a steel cradle under the floor boards. The car is assembled of standard parts, including such units as Borg & Beck clutch, Mechanics Machine selective sliding gearset, Brown-Lipe-Chapin differential, Jacox steering gear and Thermoid brakes. The gearset and clutch form a unit with the engine and the control levers are overhung from the gearset case within easy reach of the natural driving position. The drive is Hotchkiss with two 4-in. universal joints and a seamless tubing propeller shaft. Springs are semi-elliptic, wheels artillery type, and the tire equipment consists of 32 x 3½ in. pneumatics with non-skid in the rear. The wheelbase is 116 in., weight 2420 lb., loading space 6 ft. long, 4 ft. high and 3½ ft. wide.

Saxon Offices in London and Paris

DETROIT, March 1—The Saxon Motor Car Corp. is about to open export offices in London and Paris. The Paris office will be in charge of M. Eller and the London office under the supervision of D. Eller, both of New York. They sail for Europe next week.

Aument & Gillespie, Consulting Engineers

NEW YORK, March 4—Carroll M. Aument, formerly an engineer of the Wright-Martin Aircraft Corp., has resigned his position and opened a consulting, designing and sales engineering office at 87 Nassau Street under the name of Aument & Gillespie.

Wilson Body Co. to Deliver 63,000 Bodies

DETROIT, March 3—The C. R. Wilson Body Co.'s business for January exceeds $600,000. Orders already on the books call for the 1919 delivery of 63,000 bodies. The company is making bodies for the Ford Motor Car Co., Paige-Detroit Motor Car Co., Hupp Motor Car Corp., Liberty Motor Car Co., Oakland Motor Car Co., Reo Motor Car Co., Saxon Motor Car Corp. and Willys-Overland Co.

Packard Back in Passenger Production

DETROIT, March 5—The Packard Motor Car Co. has completed its shift from 100 per cent war production back to commercial work. It has resumed the manufacture of passenger cars, the first of which will be ready in May. Commercial truck manufacture has been under way for some time.

Nash Net Profits $1,473,638 for 1918

KENOSHA, WIS., March 3—Net profits of the Nash Motors Co. for the year ended Dec. 1, 1918, after all necessary deductions were made, amounted to $1,473,638, which is $554,146 less than the $2,027,784 earned from Aug. 31, 1916, to Dec. 1, 1917. The surplus of $2,503,831 was $87,697 more than $2,416,-134 in 1917.

The balance sheet of Nash Motors Co. as of Dec. 1, 1918, compares as follows:

Assets

	1918	1917
Property less depreciation	$2,911,633	$3,261,175
Miscellaneous investments	103,941	117,241
Liberty bonds	800,000	......

Inventories	4,889,102	4,607,830
Prepaid expenses	5,316	4,275
Total	$11,936,385	$10,111,256

Liabilities

	1918	1917
Preferred stock	$5,000,000	$5,000,000
Common stock	50,000	50,000
Accounts payable	1,788,674	1,311,126
Accrued taxes	764,141	355,109
*Reserves	1,829,739	978,887
Surplus	2,503,831	2,416,134
Total	$11,936,385	$10,111,256

*These reserves do not cover Federal taxes which have been provided for by deduction from cash and receivables as above shown.

—

Commerce Declares Dividend

Commerce Motor Car Co., Detroit, 1½ per cent on capital stock, payable to stockholders of record on April 1; 1 per cent, extra dividend, payable to stockholders of record April 1.

—

Pennsylvania Rubber Declares Dividends

The Pennsylvania Rubber Co., Jeannette, Pa., quarterly dividend 1¾ per cent preferred, 1½ per cent common.

—

Republic Truck Dividend

The Republic Motor Truck Co., Inc., Alma, $1 a share on its common stock, paid Feb. 15 to all stockholders of record Jan. 31.

—

Hebb Dividends

Hebb Motors Co., Lincoln, Neb., 7 per cent quarterly, preferred; 10 per cent, common. The capital of the company has recently been increased from $1,250,000 to $2,500,000.

—

Chandler Declares Dividend

The Chandler Motor Car Co., Cleveland, has declared a quarterly dividend of $3, payable April 1, to stockholders of record March 11.

—

Swinehart Declares Extra Dividend

AKRON, March 5—Directors of the Swinehart Tire & Rubber Co. have authorized the payment of a dividend of 2 per cent in cash on April 15 to stockholders of record March 31, also an extra 10 per cent in preferred stock on March 5 to stockholders of record Feb. 20. These are the first dividends on common stock of this company authorized since Oct. 15, 1917.

Sales in 1918 amounted to $3,910,000, an increase of 100 per cent over those of 1917. Net earnings, it is said, amounted to $500,000. There is $800,000 common stock outstanding. The only change in officials was the addition of C. C. Lee of the Union Commerce National Bank, Cleveland, as director.

*Including Federal taxes accrued.

—

Stromberg Extra Dividend

The Stromberg Motor Devices Co., Chicago, has declared an extra dividend of 25 cents a share in addition to the regular quarterly dividend of 75 cents a share, payable April 1, to stockholders of record March 15.

—

Wisconsin Motors Stock Issues

MILWAUKEE, March 1—The Wisconsin Motor Mfg. Co. is marketing an issue of $800,000 of 8 per cent cumulative preferred stock at par. In addition, the company has $1,000,000 of common stock, valued at $1,500.000 at market value. Its net sales for 1918 exceeded $5,700,000.

—

Hilo Varnish to Share Profits

BROOKLYN, March 3—The Hilo Varnish Corp. has decided to distribute half the profits of the company annually among its employees, giving each a share proportionate to his salary and the length of time he has been in its service.

Fisk Sales $6,765,482 Ahead of 1917

CHICOPEE FALLS, MASS., March 4—Net sales of $36,682,163 are reported in the financial report of the Fisk Rubber Co. for the year ended Dec. 31 last, which is $6,765,482 more than the $29,916,681 in 1917. Net profits for the year are $3,760,279 after deducting manufacturing cost, depreciation, interest, etc. Federal taxes paid in 1917 amounted to $549,913, and in 1918 the estimated provision for Federal and excess profits taxes was $1,253,426.

The balance sheet, dated Dec. 31, 1918, compares as follows with the reports of the two previous years:

Assets

	1918	1917	1916
Real estate, buildings, machinery, etc.	$7,780,649	$7,146,447	$5,876,308

Allis-Chalmers Sales $35,031,233 for Year

MILWAUKEE, March 5—Gross sales of $35,031,233 are reported in the financial report of the Allis-Chalmers Mfg. Co. for the year ended Dec. 31, 1918, an increase of $8,901,916 over $26,129,317 in 1917. Profits, before taxes were deducted, amounted to $9,754,748 compared with $5,308,790 in 1917. Manufacturing costs in 1918 were reduced to 66.6 per cent of the gross business handled, as against 73.27 per cent in 1917 and 75.61 per cent in 1916. The total surplus as of Jan. 1, 1919, after all necessary deductions were made, was $8,439,470.

—

Universal Mfg. Co. in Bankruptcy

MILWAUKEE, March 1—The Universal Mfg. Co., 491 Broadway, manufacturer and dealer in farm lighting plants, electrical devices and specialties, has filed a petition in bankruptcy, scheduling liabilities at $23,820 and assets at $21,-912. Julius J. Goetz has been elected trustee. Creditors will meet March 13 at 10 a. m. in the office of Referee John F. Harper, Federal Building, Milwaukee.

Urge Road Building Program

(Continued from page 544)

ably expected. Soldiers needed for farm work.

Illinois—About 40,000 are idle, of which 4000 are women. About 5000 men to be given work on State roads to cost $60,000,000 and 3000 to work on State buildings. No feeling of pessimism nor any undue optimism.

Indiana—Situation is far more alarming. About $42,000,000 available to be spent in public works. Private capital is holding back in building because of high labor and materials costs. About 50,000 soldiers have returned and been given places, many employers carrying extra men on the pay roll.

Kansas—Ready to use more men today. Will have $200,000,000 wheat crop and must have much labor in Spring and Summer. Situation very satisfactory and no reason to think that all soldiers will not be employed when they return.

Kentucky—Situation is good, except in some coal districts. Many opportunities for work on farms.

West Virginia—Less than half of 80,000 miners are working full time. Great efforts must be made if men are to be given a livelihood.

Louisiana—Labor conditions fairly satisfactory. There is a shortage rather than an oversupply of labor. Not a soldier has returned who has not taken his old job or a new one. As trade of country expands great opportunities for work will open up.

Maryland—Up to this time no labor shortage. About 13,000 soldiers have been given jobs.

Maine—Greatest trouble found in getting soldiers to come back to jobs that await them. Employers expect to face a sharp labor shortage in a year.

Michigan—Condition of copper market has hit many mines. On the whole, however, the situation appears to be good, certainly it is not serious. The State is in a good position to take care of all her soldiers. Detroit has more men idle than in normal times, due to cutting off of war work.

Minnesota—No labor troubles have come up and no great unemployment problem seems imminent. Of the 12,000 soldiers who have returned, 4674 have taken their old jobs, and of the remainder all except about 800 have been placed in new jobs. The boys from the farms show a tendency to stop in the cities and enter industrial life. Building operations in Spring may prove disappointing.

Several mayors objecting to the reports made by the governors, and especially those city executives from the far western states where there has been considerable trouble claimed that the state executives were not closely in touch with the conditions and did not know how serious the labor surplus is.

Governor Edge of New Jersey recommended that the Federal Government should release industry from Government restraint at once, and Governor Cox of Ohio combatting this view stated that the Federal powers should continue to interest themselves in industry. He said that the country was being asked at present to listen to two groups of extremists, one wanting prosperity held up in order to "teach labor an object lesson" and the other anxious to proceed with projects regardless of costs.

He urged road building as a buffer employment measure and suggested the creation of an organization in Washington to find out for the Federal Government what should be a fair price for gravel, crushed stone and other road building material, declaring that artificial prices fixed by unpatriotic men were holding up road construction.

Roger W. Babson, representing the Department of Labor, presented seven propositions which, he said, if adopted generally, would allay fear and start the country right in its attempt to get back to a proper industrial basis. His suggestions included:

1. Begin at once construction of all public works possible, including public buildings—especially schoolhouses.
2. Get behind the "build-a-home" movement by asking for a quota for your community and then publishing each week in your daily papers how you are keeping up with that quota.
3. Get your State this Summer to build its full quota of federal roads on the 50-50 basis and appropriate a larger sum than ever before for State roads.
4. See that the traction properties of your State and city receive fair treatment, remembering that the transportation system of a city determines more than any other one thing its growth and prosperity.
5. Urge labor to give greater service for its wages, but remember that high wages increase the home market for goods, so that the more money paid in wages the more goods will be purchased and the greater will be the prosperity of your state and city.
6. Get your councils of defense and safety committees to advertise as much now to get people to buy as they advertised during the war to get people to economize.
7. Help Secretaries Wilson, Lane and Redfield and the other cabinet chiefs in their efforts to provide greater opportunities for both capital and labor.

Lieut.-Governor Oglesby of Illinois said that the time is ripe for industry to assume its natural place and also to let the law of supply and demand again come into operation. Governor Catt of Florida said both wages and prices of commodities must come down before industry could resume a normal pre-war basis.

An address was made today by S. M. Williams, President of the Highways Industry Association, in which he discussed the value of road building, not only as a buffer employment for labor but also in its direct relation to the development of the public prosperity and welfare generally. He replied to the speech of Governor Cox, quoting prices for brick and other road materials to show that they were not exorbitant at present, and stated that as 75 per cent of the cost of road construction is labor, there is not much possibility of reducing the cost of road building so long as the present wages maintain.

Discussing business and labor conditions generally, Mr. Williams urged the public to cease looking for a reversion to the prices of 1914, and said that prosperity could only be found when the business men and general public realized that it is necessary to go ahead now with production and expenditure.

Problems of Tractor Design Discussed at Kansas City

(*Continued from page* 546)

It was pointed out in the discussion of this paper that the fuel question has an important bearing on the sale of American automotive apparatus in South America. At the present time gasoline sells in Buenos Ayres at 62 to 75 cents per gal. and it is absolutely necessary to lessen the cost of fuel before much demand for automobiles and tractors can be hoped for from that country.

The paper on "The Principles of the Wheel Farm Tractor" by E. R. Hewitt was the same as that presented at the winter meeting of the society. This paper, which had been in the hands of the membership in printed form for some time, brought out considerable contributed discussion. Mr. Hewitt's conclusion that the maximum traction which it is possible to obtain with a cleated wheel is equal to the shearing resistance of the ground over the arc of the circle described by the outer edge of the cleats in passing through the ground was taken exception to by several. It was pointed out that if this was correct a ½ in. cleat would be practically as effective as a 5 in. cleat.

Mr. Greer said that Mr. Hewitt overlooked the advantages of spiral extension cleats, which clear themselves of dirt and which do not cause shearing of the ground. Mr. Greer also disagreed with Mr. Hewitt regarding the relative advantages and disadvantages of the front drive. He said that with front driven tractors over 85 per cent of the weight may be carried on the driving wheels and that the front drive is advantageous on hills. Moreover, plowing represents only about 50 per cent of the work of any tractor, and some of its other uses should be considered in determining the best type.

Vacuum Gage as Power Indicator

Mr. Shoop brought out the point that a wheel with involute cleats would enter and leave the ground perpendicularly. Mr. Horning spoke commendingly of the use of the vacuum gage as a power indicator described by Mr. Hewitt. He said that the conditions of operation of the average tractor engine corresponded to curve 1, Fig. 3, in the paper. As regards the statement that engines were abused in service, there is no load which can possibly be injurious to any first class tractor engine.

Mr. Lohman, who was described as the engineer of a large community farm in Montana, in a written discussion regretted the tendency of tractor manufacturers to over-rate their machines. He said that 50 to 60 per cent of its rated capacity is all the work that a farmer could hope to obtain from the average tractor. The maximum that he had ever been able to get in continued service was 80 per cent of the rated capacity. He also pointed out the important fact that good weather plays a big part on the work of a tractor.

Mr. Lohman took exception to a statement made by Mr. Hewitt regarding the relative merits of wheeled and creeper type tractors. He said that a creeper type tractor when passing over a plowed field will leave as the only sign of its passage a series of splashes of loose earth. Prof. Moyer spoke of the results he had arrived at in experiments on the traction resistance of wheeled tractors, and especially the dependence of that resistance upon the wheel diameter.

Scientific Research in Tractor Design

The last paper of the afternoon was that by Prof. White on "The Redesign of Agricultural Machinery" for tractor work. Prof. White paid a tribute to the men who invented our principal agricultural machines. He said they possessed genius, enterprise and courage, but for the most part they lacked technical education. Most of their work had been done on a cut and dry basis, and as they had been so successful, their successors followed in their footsteps and continued to work by empirical methods. Prof. White asked whether the present generation would have nothing to add to the achievements of these pioneers, and he believed that the great development of the near future would be the application of scientific research work to the elucidation of problems in implement design.

Committees Appointed on Speed of Belts

A meeting of the tractor division of the Standards Committee was held at the Sweeney School on Tuesday morning, most of the members being present. The chief topic of discussion was that of belt speeds. A standard belt speed of 2600 ft. per minute was adopted by the Society last year, but it was found that this is a little too low, especially for the heavier tractors. The subject was discussed at great length and the consensus of opinion seemed to be that two or three different standard belt speeds would be required, ranging perhaps from 2800 to 3500 ft. per minute. Some consideration was also given to belt speeds suitable for small machines usually driven from stationary farm engines, but it is likely that this subject will be assigned to the stationary and farm engine division. A subcommittee is to be appointed to gather data regarding desirable belt speeds and to confer with the American Society of Agricultural Engineers and the National Vehicle and Implement Association on the subject.

Drawbar Height

Another topic discussed was that of drawbar height. This also has been standardized, the standard height being 17 in., but it has been found that this does not fully meet the requirements, and it is likely that a range of drawbar height will be adopted in the future. A subcommittee will be appointed to look after this matter. The subject of a standard drawbar connector, on which Mr. Greer of the Four Wheel Drive Co. has been working, was revived, and a preliminary report was received from a sub-committee on standard wheel rim punching.

Tractor Trials in Great Britain

(*Continued from page* 547)

threshing machine than is available in stock. Threshing here has been done mostly by steam power with traction engines which draw the threshing machines and a stacker; and these engines are more powerful than the average tractor, unless the latter is overloaded.

Another seeming market is for either a narrow or a reducible tread tractor chiefly for export to the West Indies for use in sugar and beet plantations. The French have a few promising machines of this sort, chiefly listed for working between vine rows, but they are for the most part too light and not powerful enough for other purposes.

Another point for tractor makers to note is that the exposed tractor wheels with bull-ring drive are not wanted here, because it is found that the teeth become choked. An all enclosed drive is desired, or, at the most, an exposed chain drive. The remark made previously that tractor trials are being developed by the implement makers is amply borne out by the use of the bull gear and cast metal gear exposed drive. Neither from an engineering nor a user's point of view is this sort of drive fitted for a hard worked tractor; but rather only machine cut gear of small dimensions and wholly enclosed in oil-tight cases.

The chain-track form of tractor has no monopoly of favor here. At present one make of this type is being assembled here, presumably to reduce the cost of freight.

The Fordson interests have a factory in course of building at Cork, Ireland, which may be expected to have an important effect on the price and output of that machine.

Commercial Treaties With South America

WASHINGTON, March 3—The United States is negotiating with the countries of Latin America to secure uniform recognition and taxes for traveling salesmen representing American firms in those countries. The new treaty has already been ratified with Uruguay and Guatemala, and provides that the business representatives will be accredited by the United States Department of Commerce and given a special single license that will carry them throughout the country they desire to visit without the payment of special taxes in every section as has heretofore been the custom. Provisions also arrange for a schedule to be drawn whereby samples will be admitted, in some instances free of duty, and in others by bond to re-export them within six months of entry.

Aluminum Production Falls 10 Per Cent

WASHINGTON, March 4—Aluminum production in 1918 was valued at $41,159,225, a decrease of $4,722,775, or 10 per cent from the value in 1917. The decrease is due very largely to a decline in the price of that metal during 1918, and does not represent a corresponding decline in quantity of output.

Changes in Nash Sales Force

KENOSHA, March 3—W. W. Smith has been appointed manager of passenger car sales of the Nash Motors Co. to succeed R. P. Bishop, who has resigned. He has been with the factory for the past two years. In 1909 he was connected with the Speedwell Motor Car Co. In 1912 he became sales manager of the American Lock Nut Co. and was later with the Thomas B. Jeffery Co. in an executive capacity, Lts. W. L. Tenney and Haskel Bliss will assist him. Both of these men were released recently from military service.

—

Rex D. Gilbert, Philadelphia, has been elected secretary and treasurer of the Oldfield Tire Co., Cleveland, the new concern organized by Barney Oldfield, the ex-car racer. Mr. Gilbert was with the Firestone Rubber Co. for the past six years.

—

A. L. Nelson has been appointed chief engineer of the Premier Motor Corp., Indianapolis, succeeding C. S. Crawford, who has been promoted to director of engineering and assistant general manager. During the war, Mr. Nelson was consulting engineer of Aircraft Armament at McCook Field, Dayton.

—

John H. Diehl has been elected vice-president of the Mason Tire & Rubber Co., Kent, Ohio.

—

Maj. William Mitchell Lewis, for many years a car manufacturer of Racine, Wis., has been promoted to lieutenant-colonel in the Signal Corps, U. S. A., of the American Army of Occupation, according to official word received here.

—

George B. Norcross has been placed in charge of the Detroit branch of the Hess Steel Corp., Baltimore. Previously he represented the company in this district.

—

Porter Opens New York Office

DAYTON, OHIO, March 3—Finley R. Porter, who completed his work with the Division of Military Aeronautics on March 1, will open headquarters in New York at the Engineers' Club on March 6. R. B. Porter, his son, will be associated with him in his future plans. Mr. Porter's immediate plans call for designs of some heavy engines for transatlantic ships, and after that he will no doubt enter the automobile field again to begin production of the F. R. P. cars in addition to building two or three types of aeronautical engines. Mr. Porter has been with the Bureau of Aircraft Production for the last 10 months as chief motor engineer.

—

Markley Body Co. Opens in Detroit

DETROIT, March 4—The Markley Commercial Body Co., with its factory and general offices in Pontiac, has opened a branch here at 728 Cass Avenue.

Men of the Industry

Changes in Personnel and Position

Kramer New Vice-President of Willys-Overland

TOLEDO, March 1—C. O. Miniger, vice-president in charge of production of the Willys-Overland Co., Toledo, has retired and will devote his entire time to his duties as president and general manager of the Electric Autolite Corp. Leroy Kramer, for many years vice-president in charge of manufacture of the Pullman Co., Chicago, and who for the past six months has been Federal manager of the United States Railroad Administration for the Southwestern district, St. Louis, has succeeded Mr. Miniger.

—

C. R. Miller, former assistant to the vice-president of the Willys-Overland Co., has been appointed works manager for the factory.

—

F. A. Petrie, field manager of the Dort Motor Car Co., Flint, will leave in May for a business trip through South America.

—

Walter H. Schwab, formerly president and general manager of the Auto Parts Mfg. Co., Milwaukee, has become secretary-treasurer of the General Mfg. Corp., which has taken over the business of the Minn Billiard Co., and will manufacture talking machines, pool and billiard tables, motor car specialties, parts and accessories.

—

W. B. Huntley, until recently a lieutenant in the Ordnance Department, has joined the sales force of the United Alloy Corp., Canton. Prior to his enlistment he was affiliated with the Crucible Steel Co. of America.

—

Daniel M. Crouse, vice-president and director of the Bossert Corp., Utica, died on Feb. 19.

—

Morris E. Fuller, founder of the Fuller & Johnson Mfg. Co., Madison, Wis., died at his home in Schuyler, Neb., on Feb. 14, at the age of 98. Mr. Fuller retired from active business about 20 years ago. He was one of the earliest dealers in farm implements in the Middle West.

—

Judge William J. Turner, Milwaukee, president of the Turner Mfg. Co., Port Washington, Wis., died Feb. 15 at the age of 71 years. His son, Lee H. Turner, is vice-president and general manager of the company. Judge Turner occupied the circuit court bench here for the last ten years.

Unwin to Manage Reo Branch

LANSING, March 4—Maj. Harry Unwin has been appointed manager of the Chicago branch of the Reo Motor Car Co. Major Unwin has just been released from the Ordnance Department and for several months has made his headquarters in this city, where he has had supervision of the tractor contract which the Reo company was completing for the government.

—

W. E. Perrine, assistant general manager of the Standard Parts Co., will leave Cleveland to enter the executive and production department of the Chevrolet division of the General Motors Co., with headquarters in New York. He will take up his new duties March 1.

—

L. F. Jalagas, formerly in the wholesale sales department of the Reo branch in Chicago, has become wholesale manager for the South West Motor Co., Kansas City distributer of Reo and Jordan cars.

—

List Obsolete and Active Planes

WASHINGTON, March 3—A list of airplanes that are considered active, obsolescent and obsolete has been compiled by the Department of Military Aeronautics and a policy has been formulated providing that only repair spare parts can be manufactured for obsolescent planes. A policy for the disposition of the obsolete planes will be announced later. The obsolescent planes will be used until either by accident or wear and tear they are beyond use and it will be left to the judgment of the officers at the fields to decide this.

Following is the list of planes:

Active

Planes	Engine
Curtiss JN4H (JN4HB)	Hisp.-Suiza Model 1
Curtiss JN6HO (JN4HG)	Hisp.-Suiza Mod. E
Curtiss JN7H (JN6HB)	Liberty 12
De Haviland 4 (JN6HP)	Le Rhone 80 HP
USD9A (JN6HG1)	
SE-5 (JN6HG2)	
VE-7	
S4-C	
Martin Bomber	
Hydros	
Lepere	
Handley-Page	
Spad	
Sopwith Dolphin	
Caproni	

Obsolescent

Curtiss JN4A	Curtiss OX2
Curtiss JN4B	Curtiss OXX3
Curtiss JN4D	Curtiss OX5
Canadian JN4	Hispano-Suiza Model A
Thomas Morse Scout	Gnome

Obsolete

Curtiss R4	Thomas Morse 8
Curtiss R2	Curtiss Model O
Curtiss N8	Curtiss OXX
Curtiss Twin	Curtiss OXX-2
LWF	Curtiss N-8
Standard J-1	Sturtevant 5-A
L-2	Hall Scott A5A
R-6	Hall Scott A7A
Martin R	Lawrence
Standard D	Clerget 9
Heinrich C-1	Curtiss V-2
Aero Marine	Curtiss V-X
Boeing	Wright 6-Cyl.
Martin TT	Salmson M-9
Martin R6	Renault 12
Standard H-2	Renault 8
Standard H-3	Sturtevant 4-cyl.
Sturtevant S-4	Aero Daimler 6-cyl.
Bristol Fighters	Curtiss Type S
Burgess Hydroplane	Laviateur 8

Detroit's 18th Show a Success

DETROIT, March 3—Detroit's eighteenth annual show is in full swing. It opened Saturday night in the Crosstown garage. Forty-five pleasure cars, 33 trucks, three tractors and automobile accessories are represented.

Great crowds visited the show Saturday night and all day Sunday throngs passed up and down the long lanes of cars. As early as Monday afternoon exhibitors were beginning to label numerous cars "sold," and every indication points to the complete demoralization of all previous show sales records.

The passenger car exhibits attract and hold the greatest crowds. Three tractors are on display.

Ford Will Make $250 Car

(*Continued from page* 545)

deny the interview said to have been given out to newspaper men in Los Angeles. Mr. Ford is expected in Detroit on Saturday. George S. Anderson, assistant secretary of the Ford Motor Co., said last night that he did not know anything about the correctness of the interview, but admitted that it had been reported to him late yesterday afternoon and had been taken up with the officials of the company. This is all the Ford officials claim to know about it.

Warnings for Trade With India

MADRAS, INDIA, Feb. 27—A warning has been issued from the consular officer here to American firms wishing to place orders in India, which states that no orders can be placed in America with firms not having agencies in India, since it is a Government rule that these Indian firms must certify to the receipt of articles in good order before payment can be made. Another complant deals with catalogs sent here without prices.

British Airship Stays in Air 100 Hours

ABERDEEN, SCOTLAND, Feb. 28—Remaining in the air from 2 p. m. on Sunday afternoon to 6.50 p. m. Thursday evening, a British airplane, in charge of Captain Warneford, made a record flight lasting 100 hours and 50 minutes. It ascended from Lenabo naval air station, about 25 miles north of this city. It was forced to descend, according to Captain Warneford, because of shortage of fuel and water. It carried a crew of 11 men and is equipped with beds and cooking apparatus.

Schoof-Gracey Co. to Make Ford Bodies

DETROIT, March 4—The Schoof-Gracey Co. has been organized to take over the commercial body department of the Maurice W. Fox Co., authorized Ford agents. The firm is composed of August F. Schoof and Chester W. Gracey.

Biplanes to Carry Mail to Ships

NEW YORK, March 5—The Kerr Steamship Co. is to operate a fleet of planes to deliver mail from 24 to 36 hours after the ships leave port. Mail will be carried in waterproof sacks and will be dropped on deck by the aviators.

Metz Roadster to Sell for $1,400

WALTHAM, Feb. 25—The 6-cylinder car which the Metz Co. is putting out will make its appearance about March 15 in three models. The roadster will sell for $1,400, the touring car for $1,600 and the closed car for $2,100.

Dayton Automobile Show Opens

DAYTON, March 4—The Dayton automobile show is in full swing this week. It opened Monday in one of the buildings at the National Cash Register plant. Cars, trucks and tractors are exhibited.

Procedure and Complete Forms for Validating Contracts

Washington, March 3, 1919.

SUPPLY CIRCULAR
No. 17

Subject: Procedure on claims for relief under Act of Congress approved March 2, 1919, entitled "An Act to Provide Relief in Cases of Contracts Connected with the Prosecution of the War, and for other Purposes."

The attention of the Supply Bureaus is called to the following resolution of the War Department Claims Board for their information, action and guidance:

Pursuant to the authority conferred upon it by War Department General Order No. 33, in connection with the administration of the powers conferred upon the Secretary of War under and by virtue of an Act entitled "An Act to Provide Relief in Cases of Contracts Connected with the Prosecution of the War, and for other Purposes," (copy of which Act is annexed to this resolution), the War Department Claims Board adopts the following procedure governing the presentation and payment of claims under Sections 1 and 4 thereof.

Attention is called to the fact that the Act does not authorize the execution of contracts which have not heretofore been properly executed. The Bureaus shall not execute contracts with respect to agreements covered by the Act, but shall proceed in the manner hereinafter provided.

1. *Classification of Claims*—For the purposes of administration, claims presented to the Secretary of War under this Act will be classified as follows:

Class A. Claims based on agreements made by an officer or agent acting under the authority, direction or instruction of the Secretary of War, and the nature, terms and conditions of which have been reduced to contract form or are otherwise established by written evidence.

Class B. Claims based on all other agreements covered by the provisions of Section 1 of said Act.

Forms and Procedure with Respect to Class A Claims

2. *Form and Method of Presentation.*

(a) Claims falling under Class A shall be presented in the form of "Statement of Claim Form A." hereto attached. They shall be prepared and presented in quadruplicate, each copy being duly executed and verified. The four copies shall be forwarded to the Claims Board in Washington of the Bureau with which the alleged agreement was made. Proper addresses are as follows:

Ordnance Claims Board, War Department, Washington, D. C.
Claims Board, Air Service, War Department, Washington, D. C.
Claims Board, Chemical Warfare Service, War Department, Washington, D. C.
Claims Board, Construction Division, War Department, Washington, D. C.
Claims Board, Director of Purchase, War Department, Washington, D. C.
Claims Board, Signal Corps, War Department, Washington, D. C.
Claims Board, Office Chief of Engineers, War Department, Washington, D. C.

(Claims based on agreements with the Quartermaster Corps should be addressed to the Claims Board, Director of Purchase, as above.)

(b) Attention is called to the fact that under the act these claims must be filed and duly supported by itemized statements before June 30, 1919.

(c) In all cases where settlement negotiations with respect to such agreements are now pending the negotiations will proceed without interruption, but no award can be made until after the statement of claim has been filed in Washington, and the nature, terms and conditions of the agreement certified by the proper Bureau Claims Board and approved by the claimant, all as hereinafter provided for.

(d) For further information claimants should apply to the proper Bureau Claims Board in Washington, or to its nearest local representative. All Supply Bureaus of the War Department are directed to facilitate in every way the prompt and proper presentation of these claims.

3. *Procedure in the Bureaus after Filing of Claims.*

(a) On the presentation of any claim to the Claims Board of a Supply Bureau, all copies of said claim are to be immediately endorsed as follows:

Received by......................... ....
Name of officer or agent.
....
Date,..........day of..............., 1919.

Each claim will receive an *identifying number* which shall be of a series not at present used in the Bureau, and a record made of its receipt and disposition. In the event that claims are improperly directed to a Bureau and have to be reforwarded from the Board of that Bureau to the Board of another Bureau, they are, nevertheless, to be numbered and stamped with the name of the Officer or Agent receiving them and the date so that the fact of their presentation to the Secretary of War before June 30, 1919, may be clearly established. When forwarded to another Board that Board will give them an identifying number of its series and they will thereafter be recorded and known under that identifying number.

(b) Each Bureau Claims Board upon the proper presentation of any claim is directed to examine into and determine the facts as to the nature, terms and conditions of the alleged agreement referred to in the statement of claim. If it finds that an agreement within the provisions of Section 1 of said Act was entered into, it will make a certificate in the form hereto attached, entitled "Form C." Such certificate shall not be executed except when it is attached to (1) an agreement heretofore reduced to contract form, or (2) a purchase order heretofore signed, or (3) a procurement order or notice of award heretofore signed which sets forth all the terms and conditions of the agreement, or (4) a document to be prepared under the supervision of such Bureau Claims Board fully setting forth the nature, terms and conditions of the agreement, and which may be in the form of such contract or order as should in due course have been formulated to cover the agreement.

(c) The nature, terms and conditions of the agreement thus established and certified shall be submitted to the claimant and no award can be made until the claimant's acceptance and approval of the certificate has been endorsed thereon

(d) The Bureau Claims Boards are hereby authorized and directed to proceed, on the basis of the agreement thus established, to make detailed examination of the claim and to recommend a fair and equitable basis for the adjustment, payment or discharge thereof. For that purpose, so far as consistent with these or subsequent instructions of the War Department Claims Board, the Bureau Claims Boards may make use of the machinery and procedure which has heretofore been established for the negotiation

of settlement agreements on properly executed contracts which have been suspended or reduced.

(e) The adjustment, payment or discharge shall be recommended in the form of an award or a series of awards using the form attached hereto entitled "Award Form 1," where a single award is made covering the entire agreement, or the form attached hereto entitled "Award Form 2," where the award is one of a series, or the form attached hereto entitled "Award Form 3," where the award is the last of a series of awards. In every case the award shall bear a serial number corresponding to the serial number of the agreement, and where a series of awards are made with respect to a single agreement each award of the series shall be given a consecutive sub-letter, as A, B, C, etc. Each award must be submitted to the claimant and his acceptance endorsed thereon and must be approved by the Bureau Claims Board and by the War Department Claims Board prior to payment.

(f) Wherever, in the judgment of the Board or Officer charged with the duty of recommending a fair and equitable basis upon which the agreement shall be adjusted, paid or discharged, it is to the best interests of the United States to do so, a separate award may be made with respect to any portion of the agreement which has been sublet or with respect to any other clearly separable item of the claim.

(g) When the award is made with respect to any portion of the agreement which has been sublet, payment thereon shall be made in accordance with paragraph 4 of the Act, and disbursing officers are authorized and required to demand that the prime contractor present satisfactory evidence of having paid each sub-contractor with respect to whom the award has been made, or of the consent of each sub-contractor to look for compensation to said prime contractor only; and in the case of the failure of said prime contractor to present such evidence or such consent the disbursing officer shall pay directly to each sub-contractor the amount found to be due him under such award.

Form and Procedure with Respect to Class B Claims

4. *Form and Method of Presentation.*

(a) Claims falling under Class B shall be presented in the form of "Statement of Claim Form B" hereto attached. They shall be prepared and presented in sextuplicate, each copy being duly executed and verified. The six copies shall be forwarded to the Board of Contract Adjustment, Munitions Building, Washington, D. C.

(b) Attention is called to the fact that under the Act these claims must be filed before June 30, 1919.

5. *Procedure by the Board of Contract Adjustment on Class B Claims.*

(a) Class B claims shall be submitted to the Board of Contract Adjustment which, in handling them, will follow the procedure above outlined for Class A claims so far as it is applicable; but those claims which are based upon alleged agreements entered into with an officer or agent acting under the authority, direction or instruction of the Secretary of War shall be kept separate and given numbers of a different series from those entered into by an officer or agent acting under the authority, direction or instruction of the President; and the forms of award used by the Board of Contract Adjustment shall provide for signature by that Board and approval by the War Department Claims Board.

(b) The Board of Contract Adjustment will establish, under the direction of the War Department Claims Board, procedure for the proof of claims pending before it.

(c) The Board of Contract Adjustment may, in any case where the nature, terms and conditions of the Agreement have been established and certified by it, refer the claim to the appropriate Bureau Claims Board for action and for recommendation of a fair and equitable basis upon which the agreement should be adjusted, paid or discharged, and the Bureau Claims Board shall then proceed in the manner provided in sub-sections d, e, f and g of Section 3 hereof and in the following General Provisions:

General Provisions

6. Before executing any certificate as to the nature, terms and conditions of an agreement the Bureau Claims Board or the Board of Contract Adjustment shall satisfy itself that the agreement comes within the provisions of Section 1 of the Act. Where, with respect to any claim, a Bureau Claims Board or the Board of Contract Adjustment finds that no agreement within the provisions of Section 1 of the Act has been made, it shall certify to that effect, and transmit a copy of the certificate to the claimant.

7. In the event that the claimant is not willing to accept a finding made or an award recommended by a Bureau Claims Board he may appeal to the Board of Contract Adjustment.

8. Wherever any question arises as to whether a particular Bureau Claims Board or the Board of Contract Adjustment should pass upon a claim under these regulations, that question shall be referred for decision to the War Department Claims Board.

9. There shall be prepared and preserved within the Bureau and in the office of the Board of Contract Adjustment, for transmission to Congress under the direction of the War Department Claims Board, in each case a copy of the certificate of the Board setting forth the nature, terms and conditions of the agreement, together with a copy of the award showing the nature of the payment or adjustment thereof.

10. Attention is called to the fact that in all proceedings under the Act witnesses may be compelled to attend, appear and testify and produce books, papers and letters, or other documents.

11. Bureau Claims Boards and the Board of Contract Adjustment are directed to present to the War Department Claims Board any special cases or classes of cases in which they find that the forms provided for herein cannot adequately or appropriately be employed, and to recommend appropriate forms. BY AUTHORITY OF THE SECRETARY OF WAR: GEORGE W. BURR, Brigadier General, Assistant Chief of Staff, Director of Purchase, Storage & Traffic.

To be presented before June 30, 1919

To be prepared and executed in quadruplicate. Forward all copies to proper Bureau Claims Board, War Department, Washington, D. C.

STATEMENT OF CLAIM FORM A

(To be used in connection with agreements made by an officer or agent acting under the authority, direction or instruction of the Secretary of War, and the nature, terms and conditions of which have been reduced to contract form or otherwise established by written evidence.)

STATEMENT OF CLAIM FOR RELIEF UNDER ACT OF CONGRESS APPROVED MARCH 2, 1919, ENTITLED "AN ACT TO PROVIDE RELIEF IN CASES OF CONTRACTS CONNECTED WITH THE PROSECUTION OF THE WAR, AND FOR OTHER PURPOSES"

To the Secretary of War,

Sir:—

The Claimant, Name..,
Place of business..,
P. O. Address..,

represents,

1. That during the emergency arising from the declaration of war with the German Empire and prior to November 12, 1918, and on or about the......day of................, 19.., the claimant entered into an agreement with an officer or agent acting under the authority, direction, or instruction of the Secretary of War for

(Here state nature, quantity, unit and aggregate price of the equipment, materials, supplies, services, facilities or other matters covered by the agreement.)

2. That the agreement was entered into in good faith for purposes connected with the prosecution of the war, and the claimant had performed the said agreement in whole or in part, or had made expenditures or incurred obligations upon the faith thereof, prior to November 12, 1918.

(Here state briefly facts showing that there was some performance, expenditure or incurring of obligations on the faith of alleged agreement prior to November 12, 1918.)

3. That the claimant undertakes to furnish prior to June 30, 1919, to the Secretary of War or to such person or persons as he may direct, a properly itemized and duly verified statement or series of statements showing the amount claimed to be due for articles or work delivered and accepted, and also any additional amounts claimed as reimbursement and remuneration for expenditures, obligations and liabilities necessarily incurred, including work, labor and services necessarily rendered, in performing or preparing to perform said agreement.

4. That hereto attached is an attested copy or copies of the best written evidence within the claimant's control of the nature, terms and conditions of the said agreement in the form of

(Here insert a brief description of the written evidence of the agreement as "unsigned contract," "Improperly signed contract," "purchase order," etc. If the agreement was reduced to writing in the form of a contract, purchase order or procurement order, an attested copy of such contract or order should be attached. If the agreement is supported only by letters, telegrams, etc., attested copies of such written documents should be attached and here described. Attested copies of the documents must be attached to each copy of the statement of claim and the claimant must furnish in each case four additional attested copies of the documents referred to in this paragraph.)

5. That the said agreement has not been executed in the manner prescribed by law.

And the claimant requests the Secretary of War to adjust, pay or discharge the said agreement upon a fair and equitable basis as provided in the Act of Congress approved the 2nd day of March, 1919, and entitled "An Act to Provide Relief in Cases of Contracts Connected with the Prosecution of the War, and for other Purposes."

STATEMENT OF CLAIM FORM B

(To be used in connection with all agreements by an officer or agent acting under the authority, direction or instruction of the President, and in connection with any agreement made by an officer or agent acting under the authority, direction or instruction of the Secretary of War, the nature, terms and conditions

of which have NOT been reduced to contract form or otherwise established by written evidence.)

STATEMENT OF CLAIM FOR RELIEF UNDER ACT OF CONGRESS APPROVED MARCH 2, 1919, ENTITLED "AN ACT TO PROVIDE RELIEF IN CASES OF CONTRACTS CONNECTED WITH THE PROSECUTION OF THE WAR, AND FOR OTHER PURPOSES"

To the Secretary of War,
Sir:
The Claimant, Name.....................................,
Place of business...,
P. O. Address..,
represents,

1. That during the emergency arising from the declaration of war with the German Empire and prior to November 12, 1918, and on or about the .... day of ...., 19.., the claimant entered into an agreement with an officer or agent acting under the authority, direction or instruction of the Secretary of War (President of the United States) for

(Here state nature, quantity, unit and aggregate price of the equipment, materials, supplies, services, facilities or other matters covered by the agreement.)

2. That the agreement was entered into in good faith for purposes connected with the prosecution of the war, and the claimant had performed the said agreement in whole or in part, or had made expenditures or incurred obligations upon the faith thereof, prior to November 12, 1918.

(Here state briefly facts as to such performance, expenditures and obligations prior to November 12, 1918.)

3. That the said agreement has not been executed in the manner prescribed by law.

4. The nature, terms and conditions of said agreement are as follows: *(The nature, terms and conditions must be specifically stated so that the Board may from the statement decide whether they constitute an agreement within the said Act.)*

5. The facts relied upon by the claimant to establish the existence, terms and conditions of such agreement are as follows: *(Here insert every fact upon which claimant relies to establish the alleged agreement or embody them in a statement incorporated by reference. The acts of the parties and the circumstances establishing the agreement and its essential elements should be set out free from argumentative or irrelevant matter.)*

6. Attached hereto is an itemized and duly verified statement or series of statements,* showing in detail the articles or work delivered and accepted by the United States and the exact nature and extent of all expenditures, obligations or liabilities necessarily incurred, including all work, labor and services necessarily rendered by the claimant in performing or preparing to perform that portion of the agreement additional to the above recited articles or work delivered and accepted. The aggregate amount claimed to be due from the United States to the claimant is ....dollars ($).

7. The names of all officers or agents who acted under the authority, direction or instruction of the Secretary of War (the President of the United States) in making said agreement so far as known to or ascertainable by the claimant are as follows:

Name and Rank	Station
....	....
....	....
....	....

8. The following persons other than the aforesaid officers or agents have personal knowledge of the nature, terms and conditions of said agreement:

Name and Address:

....
....
....

9. Attached hereto, as per schedule below, are copies of all writings in the possession of said claimant bearing on the existence of said agreement or its nature, terms and conditions.

(Here list all such writings attached.)

10. Attached hereto is such description as the claimant is able to give of all other writings of which said claimant has information or knowledge bearing on the existence of said agreement or its nature, terms and conditions.

And the claimant requests the Secretary of War to adjust, pay or discharge the said agreement upon a fair and equitable basis as provided in the Act of Congress approved the 2nd day of March, 1919, and entitled "An Act to Provide Relief in Cases of Contracts Connected with the Prosecution of the War, and for Other Purposes."

Signature
....
Claimant.

Note: (This certificate shall not be executed except when it is attached to (a) an agreement reduced to contract form, or (b) a signed purchase order, or (c) a signed notice of award or procurement order which sets forth all the terms and conditions of the agreement, or (d) a document prepared under the supervision of the Claims Board or Board of Contract Adjustment and fully setting forth the nature, and conditions of the agreement, all as provided in paragraph 3, sub-paragraph (b), of Supply Circular No. 17.)

AWARD FORM I

CLAIM No......

This Form to be used when a single award is to be made.

AWARD OF SECRETARY OF WAR UNDER THE ACT OF CONGRESS ENTITLED "AN ACT TO PROVIDE RELIEF IN CASES OF CONTRACTS CONNECTED WITH THE PROSECUTION OF THE WAR AND FOR OTHER PURPOSES"

Approved March 2, 1919

It appearing to the satisfaction of the Secretary of War that an agreement was entered into in good faith between ...., the claimant, and *(Give name, rank or title, and corps)*, an officer or agent acting under the authority, direction or instruction of the Secretary of War (the President of the United States) on or about the .... day of ...., 19.., during the emergency arising from the declaration of war with the German Empire and prior to November 12, 1918, for a purpose connected with the prosecution of the war; that the agreement had been performed in whole or in part, or expenditures had been made or obligations incurred by the claimant on the faith of such agreement, prior to November 12, 1918; that the agreement has not been executed in the manner prescribed by law; that the said agreement is within the provisions of the above entitled Act of Congress; that the documents attached hereto constitute a detailed statement showing the nature, terms and conditions of said agreement;† that the claimant presented his claim to the Secretary of War before June 30, 1919; that the sum of $................ will adjust, pay and discharge such agreement upon a fair and equitable basis and that such sum will not include prospective or possible profits on any part of the agreement beyond the goods and supplies delivered to and accepted by the United States thereunder and a reasonable remuneration for expenditures and obligations or liabilities necessarily incurred in performing or preparing to perform said agreement:

The Secretary of War hereby awards to said claimant the sum of $.................. in full adjustment, payment and discharge of said agreement.

The extent to which this award is made with respect to any portion of the agreement which was sub-let is as follows:

(Here insert a list of all sub-contractors whose claims against the prime contractor are covered by the award, giving the name, place of business, and P. O. address of each, together with the amount awarded with respect to each sub-contract.)

AWARD LETTER.............

AWARD OF SECRETARY OF WAR UNDER THE ACT OF CONGRESS ENTITLED "AN ACT TO PROVIDE RELIEF IN CASES OF CONTRACTS CONNECTED WITH THE PROSECUTION OF THE WAR, AND FOR OTHER PURPOSES"

Approved March 2, 1919

It appearing to the satisfaction of the Secretary of War that an agreement was entered into in good faith between ...., the claimant, and *(Give name, rank or title, and corps)*, an officer or agent acting under the authority, direction or instruction of the Secretary of War (the President of the United States) on or about the .... day of ...., 19.., during the emergency arising

* *Wherever it is possible to state the items of claim on Finance Forms 1 to 10, these forms shall be used. Copies may be obtained from local representatives of bureaus of the War Department or from the Board of Contract Adjustment at Washington. In any case such statements shall include a complete list of all subcontractors, if any, and the amount of the liability claimed to have been incurred as to each by the claimant under such agreement.*

†*These documents shall consist of the certificate of the Claims Board or Board of Contract Adjustment (Form C), including the papers thereto attached.*

from the declaration of war with the German Empire and prior to November 12, 1918, for a purpose connected with the prosecution of the war, that the agreement had been performed in whole or in part, or expenditures had been made or obligations incurred by the claimant on the faith of such agreement, prior to November 12, 1918; that the agreement has not been executed in the manner prescribed by law; that the said agreement is within the provisions of the above entitled Act of Congress; that the documents attached hereto (to an award heretofore made with respect to said agreement and marked ....) constitute a detailed statement showing the nature, terms and conditions of said agreement;* that the claimant presented his claim to the Secretary of War before June 30, 1919; that an adjustment, payment or discharge of said agreement upon a fair and equitable basis will include the allowance to the claimant of the sum of $................with respect to the following separable item:

(Here insert a description of the item or claim with respect to which the award is made, which may be any clearly separable item of the claim. If the award is made with respect to any portion of the agreement which the claimant shall have sub-let, the statement should include the name, place of business, and P. O. address of the sub-contractor.)

That it is not at this time possible to make a complete award with respect to this agreement and it is of advantage to the United States to make an award at this time with respect to said separable item, and that there is not included in this award, by itself or together with awards heretofore made with respect to said agreement, any prospective or possible profits on any part of said agreement beyond the goods and supplies delivered to and accepted by the United States thereunder, and a reasonable remuneration for expenditures and obligations or liabilities necessarily incurred in performing or preparing to perform said agreement.

The Secretary of War hereby awards to said contractor the sum of $—————— in full adjustment, payment and discharge of said item.

The extent to which this award is made with respect to any portion of the agreement which was sub-let is as follows:

(Here insert a list of all sub-contractors whose claims against the prime contractor are covered by the award, giving the name, place of business, and P. O. address of each, together with the amount awarded with respect to each sub-contract.)

Following is the complete bill, as agreed to by the Senate-House conferees, and signed:

AN ACT

To provide relief in cases of contracts connected with the prosecution of the war, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

That the Secretary of War be, and he is hereby, authorized to adjust, pay, or discharge any agreement, express or implied, upon a fair and equitable basis that has been entered into, in good faith during the present emergency and prior to November 12, 1918, by any officer or agent acting under his authority, direction, or instruction, or that of the President, with any person, firm, or corporation for the acquisition of lands, or the use thereof, or for damages resulting from notice by the Government of its intention to acquire or use said lands, or for the production, manufacture, sale, acquisition or control of equipment, materials, or supplies, or for services, or for facilities, or other purposes connected with the prosecution of the war, when such agreement has been performed in whole or in part, or expenditures have been made or obligations incurred upon the faith of the same by any such person, firm, or corporation prior to Nov. 12, 1918, and such agreement has not been executed in the manner prescribed by law. *Provided*, That in no case shall any award either by the Secretary of War, or the Court of Claims include prospective or possible profits on any part of the contract beyond the goods and supplies delivered to and accepted by the United States and a reasonable remuneration for expenditures and obligations or liabilities necessarily incurred in performing or preparing to perform said contract or order: *Provided further*, That this act shall not authorize payment to be made of any claim not presented before June 30, 1919: *And provided further*, That the Secretary of War shall report to Congress at the beginning of its next session following June 30, 1919, a detailed statement showing the nature, terms, and conditions of every such agreement and the payment or adjustment thereof: *And provided further*, That no settlement of any claim arising under any such agreement shall bar the United States Government through any of its duly authorized agencies, or any committee of Congress hereafter duly appointed, from the right of review of such settlement, nor the right of recovery of any money paid by the Government to any party under any settlement entered into, or payment made under the provisions of this act, if the Government has been defrauded, and the right of recovery in all such cases shall exist against the executors, administrators, heirs, successors, and assigns, of any party or parties; *And provided further*, That nothing in this act shall be construed to relieve any officer or agent of the United States from criminal prosecution under the provisions of any statute of the United States for any fraud or criminal conduct: *And provided further*, That this act shall in no way relieve or excuse any officer or his agent from such criminal prosecution because of any irregularity or illegality in the manner of the execution of such agreement: *And provided further*, That in all proceedings hereunder witnesses may be compelled to attend, appear, and testify, and produce books, papers and letters, or other documents; and the claim that any such testimony or evidence may tend to criminate the person giving the same shall not excuse such witness from testifying, but such evidence or testimony shall not be used against such person in the trial of any criminal proceeding.

Sec. 2. That the Court of Claims is hereby given jurisdiction on petition of any individual, firm, company or corporation referred to in Section 1 hereof, to find and award fair and just compensation in the cases specified in said section in the event that such individual, firm, company or corporation shall not be willing to accept the adjustment, payment, or compensation offered by the Secretary of War as hereinbefore provided, or in the event that the Secretary of War shall fail or refuse to offer a satisfactory adjustment, payment or compensation as provided for in said section.

Sec. 3. That the Secretary of War, through such agency as he may designate or establish is empowered, upon such terms as he or it may determine to be in the interest of the United States, to make equitable and fair adjustments and agreements, upon the termination or in settlement or readjustment of agreements or arrangements entered into with any foreign government or governments or nationals thereof, prior to Nov. 12, 1918, for the furnishing to the American Expeditionary Forces or otherwise for war purposes of supplies, materials, facilities, services or the use of property, or for the furnishing of any thereof by the United States to any foreign government or governments, whether or not such agreements or arrangements have been entered into in accordance with applicable statutory provisions; and the other provisions of this act shall not be applicable to such adjustments.

Sec. 4. That whenever, under the provisions of this act, the Secretary of War shall make an award to any prime contractor with respect to any portion of his contract which he shall have sublet to any other person, firm or corporation who has in good faith made expenditures, incurred obligations, rendered service, or furnished material, equipment, or supplies to such prime contractor, with the knowledge and approval of any agent of the Secretary of War duly authorized thereunto, before payments of said award the Secretary of War shall require such prime contractor to present satisfactory evidence of having paid said subcontractor or of the consent of said subcontractor to look for his compensation to said prime contractor only; and in the case of the failure of said prime contractor to present such evidence or such consent the Secretary of War shall pay directly to said subcontractor the amount found to be due under

Calendar

ENGINEERING

March 7—New York. S. A. E. Aircraft Meeting at Engineering Societies Bldg.

April 2—Minneapolis Section, S. A. E. — Hotel Radisson. "Implements Designed for Tractor Belt Power and Their Characteristics."

SHOWS

March 1-8—Detroit, Mich. Detroit Automobile Dealers' Assn. H. H. Shuart, Manager.

March 1-8—York, Pa. York Automobile Dealers' Assn.

March 1-15—New York Aeronautical Exhibition, Manufacturers' Aircraft Assn., Madison Square Garden and 69th Regiment Armory.

March — Scranton, Pa. Thirteenth Regiment Armory, Scranton Automobile Assn.

March—Utica, N. Y. Utica Motor Dealers' Assn. W. W. Garabrandt, Manager.

March—Philadelphia, Pa. Philadelphia Automobile Trade Assn. Passenger cars.

March 3-8 — Muskegon, Mich. Third Annual, Armory, Muskegon Lodge No. 274, B. P. O. E. John C. Fowler and George M. Friant, Managers.

March 3-8—Dayton, O., N. A. C. A. Building.

March 3-8—Columbus, O. Columbus Automobile Show Co., Memorial Building. W. W. Freeman, Manager.

March 3-8—Raleigh, N. C. Third Annual. H. B. Bolton. Manager.

March 3-8—Scranton, Pa. Ninth Annual, 13th Regiment Armory, Scranton Automobile Assn. Hugh B. Andrews, Manager.

March 3-8—Buffalo, N. Y. Buffalo Automobile Dealers' Assn.

March 3-8—Richmond, Va. Third Annual, Richmond Automobile Trade Assn., Gray's Armory.

March 5-8—Lancaster, Pa. Automobile Trade Assn., Rowe Motor Co.'s B'dg., R. W. Shreiner, Manager.

March 8-15 — New Brunswick, N. J. Armory, New Brunswick Motor Trade Assn. William Kuehle, Manager.

March 8-15 — Philadelphia, Pa. Philadelphia Automobile Trade Assn., Commercial Huseum. A. L. Maltby, Manager.

March 10-12 — Lancaster, Pa. Truck Show.

March 10-15—Paterson, N. J. Paterson Automobile Trade Assn., Fifth Regiment Armory. H. MacGinley, Show Manager.

said award; and in case of the insolvency of any prime contractor the subcontractor of said prime contractor shall have a lien upon the funds arising from said award prior and superior to the lien of any general creditor of said prime contractor.

Sec. 5. That the Secretary of the Interior be, and he hereby is, authorized to adjust, liquidate, and pay such net losses as have been suffered by any person, firm, or corporation, by reason of producing or preparing to produce, either manganese, chrome, pyrites, or tungsten in compliance with the request or demand of the Department of the Interior, the War Industries Board, the War Trade Board, the Shipping Board, or the Emergency Fleet Corporation to supply the urgent needs of the Nation in the prosecution of the war; said minerals being enumerated in the act of Congress approved Oct. 5, 1918, entitled "An act to provide further for the national security and defense by encouraging the production, conserving the supply, and controlling the distribution of these ores, metals, and minerals which have formerly been largely imported, or of which there is or may be an inadequate supply."

The said Secretary shall make such adjustments and payments in each case as he shall determine to be just and equitable; that the decision of said Secretary shall be conclusive and final, subject to the limitation hereinafter provided; that all payments and expenses incurred by said Secretary, including personal services, traveling and subsistence expenses, supplies, postage, printing, and all other expenses incident to the proper prosecution of this work, both in the District of Columbia and elsewhere, as the Secretary of the Interior may deem essential and proper, shall be paid from the funds appropriated by the said act of Oct. 5, 1918, and that said funds and appropriations shall continue to be available for said purpose until such time as the said Secretary shall have fully exercised the authority herein granted and performed and completed the duties hereby provided and imposed: *Provided, however*, That the payments and disbursements made under the provisions of this section for and in connection with the payments and settlements of the claims herein described, and the said expenses of administration shall in no event exceed the sum of $8,500,000: *And provided further*, That said Secretary shall consider, approve, and dispose of only such claims as shall be made hereunder and filed with the Department of the Interior within three months from and after the approval of this act: *And provided further*, That no claim shall be allowed or paid by said Secretary unless it shall appear to the satisfaction of the said Secretary that the expenditures so made or obligations so incurred by the claimant were made in good faith for or upon property which contained either manganese, chrome, pyrites, or tungsten in sufficient quantities to be of commercial importance: *And provided, further*, That no claims shall be paid unless it shall appear to the satisfaction of said Secretary that moneys were invested or obligations were incurred subsequent to April 6, 1917, and prior to Nov. 12, 1918, in a legitimate attempt to produce either manganese, chrome, pyrites, or tungsten for the needs of the Nation for the prosecution of the war, and that no profits of any kind shall be included in the allowance of any of said claims, and that no investment for merely speculative purposes shall be recognized in any manner by said Secretary: *And provided further*, That the settlement of any claim arising under the provisions of this section shall not bar the United States Government, through any of its duly authorized agencies, or any committee of Congress hereafter duly appointed, from the right of review of such settlement, nor the right to recover any money paid by the Government to any party under and by virtue of the provisions of this section, if the Government has been defrauded, and the right of recovery in all such cases shall extend to the executors, administrators, heirs, and assigns of any party.

That a report of all operations under this section, including receipts and disbursements, shall be made to Congress on or before the first Monday in December of each year.

That nothing in this section shall be construed to confer jurisdiction upon any court to entertain a suit against the United States: *Provided further*, That in determining the net losses of any claimant the Secretary of the Interior shall, among other things, take into consideration and charge to the claimant the then market value of any ores or minerals on hand belonging to the claimant, and also the salvage or usable value of any machinery or other appliances which may be claimed was purchased to equip said mine for the purpose of complying with the request or demand of the agencies of the Government above mentioned in the manner aforesaid.

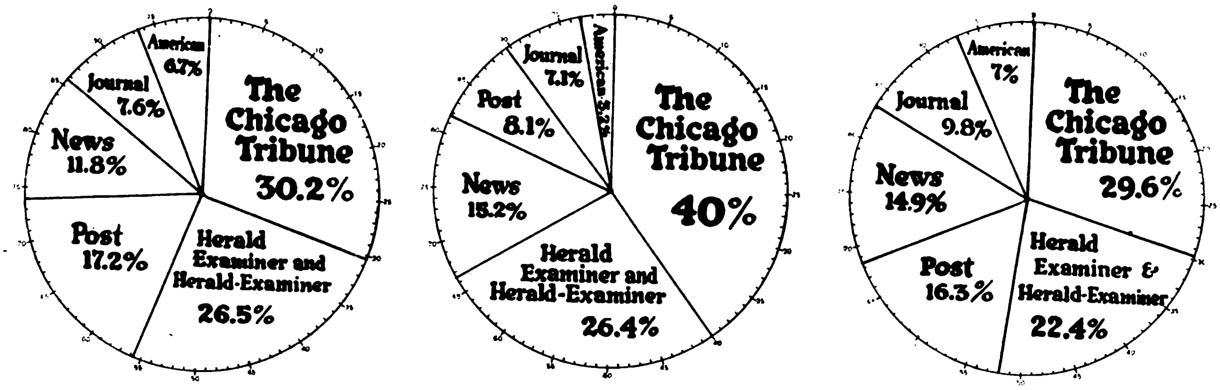
CHICAGO TRIBUNE PRINTS MORE AUTO ADS IN ONE DAY THAN OTHER PAPERS IN SEVEN

During the last six months of 1918 The Tribune printed in its Sunday issue alone more display automobile advertising than any other Chicago paper printed in all its issues. The figures are as follows:

Chicago Sunday Tribune	*168,445*	*Agate Lines*
Chicago Daily Tribune	*67,689*	"
Chicago Tribune total	*236,134*	"
Herald-Examiner total	*116,201*	"
News "	*106,554*	"
Post "	*101,832*	"
Journal "	*38,112*	"
American "	*28,903*	"

The three charts below picture the proportion of total advertising in the three subdivisions of automobile advertising printed by each Chicago newspaper during 1918:

Passenger Cars — Trucks and Tractors — Accessories



The pre-eminence of The Chicago Tribune as an advertising medium has been formally sworn to by witnesses in the million dollar libel suit of Henry Ford against The Chicago Tribune. Charles A. Brownell, advertising manager of the Ford Motor Company, testified under oath that The Chicago Tribune is "by far the best" automobile advertising medium in its territory, and E. LeRoy Pelletier swore that it was one of the few newspapers so powerful and important as to be considered a "national medium."

Inadequate Cost-Keeping Retarding Adjustment

Government Machinery Oiled to Handle Claims Rapidly but They Are Slow in Arriving

By J. Edward Schipper

DETROIT, March 11—Delays in adjusting government contracts are due to bad cost-keeping systems on the part of the contractor or subcontractor in practically every instance.

Government machinery for adjusting claims is now so lined up that there is no delay in any department, once the claims have been properly filed and audited. Where the delay is found is in the inability of the contractor to fix the sum for which he should be reimbursed by the Government.

Cost-keeping systems have been so bad in a large percentage of the work done by contractors and subcontractors that it is now necessary for the Government to employ engineers to make a survey of the work done and of the equipment, etc., in order to reach any basis for a settlement. This naturally has caused considerable delay which would have been eliminated immediately if the contractor or sub-contractor had maintained a good and complete cost-keeping system.

Detroit Claims $1,500,000,000

The total amount of money which will be paid over by the Government in re-adjustments in the Detroit district, when these are finally concluded, will be $1,500,000,000. About 30 per cent of this has already been adjusted. It is estimated that the bulk of the Ordnance and Quartermaster Department adjustments will have been made by April 1. The Bureau of Aircraft Production officials do not believe that their adjustments will be completed before July 1.

This is due to the fact that there are a great many more small concerns which have acted as sub-contractors for airplanes parts; due to the unusual nature of the business and the fact that there are so many small concerns, the cost-keeping methods have been entirely inadequate, which is resulting in a tremendous amount of work being necessary for concerns to get an accurate knowledge of just what the Government owes them.

Peculiar State of Affairs

A peculiar state of affairs exists in many instances. The concerns will tell others how the Government is holding them up on adjustments and at the same time Government officials will be pleading with the concerns to submit statements. This exists in a score or more of factories, usually in the automobile, truck and parts-making businesses, and it is a hard condition to understand. The whole matter, in fact, presents such a complex problem that in its entirety it is, at first glance, bewildering.

Just one phase of the work might be considered as a good example. It would seem that all the Government had to do, on the surface, would be to determine how much was coming to a concern and then pay the bill, but this does not take into consideration the fact that in settling, the Government is obliged to take over an immense amount of ma-

terial which it does not need under present conditions.

This material is all valuable and nearly all salable, but Government officials know that to dump this material on the market at bargain prices would upset industry to such an extent that it would be disastrous in many cases.

Therefore, to handle the matter properly the Bureau of Aircraft Production has a separate department for material disposition, and this department will not dispose of lumps of material of any nature until it has first gone into the market condition and determined whether or not the disposition or sale of that material would have a bad effect on business conditions in that particular line of goods. That is only one of the angles which is constantly arising.

Real Need For Cost-Keeping

One of the lessons of this war which business cannot fail to take to heart is the necessity for accurate cost-keeping. One of the financial papers recently pointed out that during 1918 alone, 9982 concerns failed in the United States of 35,000 new corporations during the same period. In 1917 there were 13,855 failures of 50,000 new corporations. It is stated by the Federal Trade Commission that the main cause of these failures is the lack of knowledge of the cost of production. This has been shown up so clearly in the work of the Ordnance, Quartermaster, and Bureau of Aircraft Production adjustment boards that it must be taken to heart by any of the business concerns which have had dealings with the Government during this war.

With all the complications in view, the progress being made in settling claims is remarkable. The various district headquarters of the army staff organizations have turned their entire forces over to adjustment. The production departments have now become the adjustment departments and the production inspectors who were in the plants, inspecting the manufactured articles, have been switched over to the adjustment department and are now assisting the manufacturers in making up their claims to be presented for settlement.

The contractor who is drawing up the claim and the Government officer who was previously an inspector, probably in his plant but who is now working in the adjustment department as a representative of the Government, go over the raw material, the materials in process, the special machinery, the new plant area, the labor cost, and all of the factors which enter into the settlement of a claim.

As each amount is itemized it is O. K.'d by the Government man and finally the claim is completed, whereupon it is submitted to the claim board with a recommendation from the Government or staff man as to its acceptance or modification. He will recommend its acceptance if he and the manufacturer are in agreement on all points. If they are not fully in agreement he will indicate the points at which he differs from the manufacturer.

Method of Making Claims

This claim and the recommendation of the staff man is brought to the claim board. An auditor is then sent out to the plant to go over the claim as submitted and to check up the items. When he has approved it, the claim comes before the claim board which sits in the district office, and when this board has passed the claim the contracting officer makes up a cancelling contract. This contract states that in consideration of the cancellation of the previous contract, the Government will reimburse the contractor for the sum required.

The cancelling contract is then turned over to a reviewing attorney, who goes over it and passes upon it, and it is submitted for the signature of the contractor. After he signs it the contractor is ready for payment, and this is made very quickly. From the time a claim is filed up to the time payment is received is generally about 10 days or 2 weeks, unless some complications have entered into the matter.

The Quartermaster Department, according to the district officer, expects to be all cleaned up on its adjustments by April 1, as is also the case with the Ordnance Department. The business of the Quartermaster Department in this territory, while large in money, does not cover, by any means, the same number of concerns as the Ordnance or Bureau of Aircraft Production. The Quartermaster Department has allowed about 150 claims, running from $4,000 to $500,000. It has but twelve claims still to audit. The Quartermaster Department has a force of 150 inspectors who are now on the advertising staff, and they are rapidly cleaning up the work as indicated.

Concerns which did extensive Government work, such as Anderson Electric, Peru Axle Co., J. C. Wilson, Federal and Denby, have all been adjusted. The adjustments of these five concerns alone totals $358,000, the smallest being $4,000 and the largest, $250,000. On the other hand, important accounts such as Packard, which has a great many sub-contractors, Continental, McCord, Republic, Service and Signal, are not as yet adjusted.

Some Complaints Not Justified

A strange condition exists in that some concerns, while stating that they are not in a hurry to file their claim and will require from 3 to 4 weeks additional time to do so, have stated to outside parties that the Government is slow in making adjustments. This is a situation difficult to understand but which certainly is found to exist.

One of the most difficult problems in the matter of adjustment is to allow the proper amount for new plants. The system used by the Quartermaster Department, in which it was necessary particularly for a large amount of plant area to be constructed, is to figure the cost of the new plant on a pre-war basis and sell it to the contractor on that arrangement. This has resulted in contracting concerns securing the plants for about 65 per cent of what they actually cost on a war-time figure. The Government arranges this by paying the concern 35 per cent of the cost of the plant, and since the concern has bought the plant at 100 per cent, this leaves 65 per cent as an average figure on plant cost adjustment.

Government Spirit Commendable

Another matter on which the two come in agreement in the cases of all departments is on scrap value. Where materials are obviously of no use to the Government, the plant is asked to bid on the material on the basis of the scrap value, and the material is frequently sold to them on that basis.

Throughout, the proceedings are being conducted by the Government departments in a spirit which is highly commendable. The machinery is all set to act rapidly upon all claims presented, the adjustments are being made on the most broad-minded scale, not only taking fully into consideration all losses due to cancellation of contracts but honoring all implied future business which was not in actual contract form—that

SUMMARY OF CLAIM

BASED ON B. A. P. CONTRACT FORM 60

Sheet No. | **CLASSIFICATION OF CLAIM** | **Amount Due Contractor**

(a) Finished products on hand at contract price .... $......

Less freight charges, if contract or order specifies delivery at point other than factory .... $......

(b) Cost of raw material on hand applying on this contract, and including handling charges and proper portion of overhead...... ......

10% profit on raw materials on hand ....

Cost of partly finished product on hand, including material, labor and overhead costs............. ......

10% profit on partly finished product on hand ....

Overhead expenses directly chargeable to uncompleted portion of contract ....

10% profit on overhead expenses... ....

(c) Commitments to suppliers and subcontractors chargeable directly to cancellation of contract ....

(d) Cost of special facilities (buildings, equipment, special tools, etc.) chargeable to cancellation of contract ....

Less fair value of special facilities at termination of contract...... ......

Loss in value of special facilities... ......

Pct. of total contract uncompleted. ......

Loss in value of special facilities chargeable to cancellation of contract ....

Total claim................ $......

(e) Less sale price of property purchased by contractor

Raw material .... $......

Partly finished products.... ...... $......

Finished products .... $......

Balance due contractor...... $......

is where a concern went ahead and constructed a plant to take care of a greater volume of business than the original contract called for, because it had received a letter from the Government stating that it may expect to do a business along bigger lines than the original contract, this has been fully considered in making adjustments.

On the other hand, manufacturers have asked for very heavy considerations for which the Government has not felt itself liable. In some cases concerns have charged in the time of salesmen due to their non-employment on company business while the concern was on war work. That is, where the companies have kept these salesmen on their payrolls while they were inactive as salesmen, they have in some cases attempted to charge the salaries of these men to the Government. This has not been allowed. Neither has advertising been allowed.

Makes Them All Cost-Plus Contracts

One of the virtual results of adjustment has been to make practically every completed contract a cost-plus contract. The adjustments are calculated on the basis of the expense to which the concern has gone in getting ready for Government manufacture and partially completing the contract, plus a reasonable percentage.

It is in the figuring of these costs that the weakest part of the system is found. Had every contractor and sub-contractor on a Government contract a good up-to-date, accurate cost-keeping system, practically all adjustments would have been made. There is no lack of money to make adjustments, because the original appropriations for manufacture are available for the purpose; there is no lack of speed in the Government machinery for making the adjustment. The delay is solely on the part of the contractor being unable to submit his claim, based on a set of figures which have been accurately compiled from a clear-cut, business-like cost system.

The Government is allowing a profit not in excess of 10 per cent on material, labor and overhead. The figure on overhead varies all the way from 50 per cent up to 800 and 900 per cent, but a fair average is 150 per cent. In reaching their conclusions, the Government departments are going out of their way to recognize fully the industrial assets of the company before the war and at the time the adjustment is made, to see that these concerns which did Government work do not industrially suffer from that fact.

Confidential reports are filed along with the claims which tell the article manufactured before the war, the articles manufactured for the Government in all departments, the articles manufactured for the particular department making the adjustment, the articles to be manufactured after the war, the total number of male employees before the war, total number of female employees before the war, total of male and female employees during the war, and the estimated number to be employed after the war. The percentage of the plant now on commercial production is estimated and also how long it will take to get into full commercial production. A careful note is also made on a form filed by the Bureau of Aircraft Production on the cost system used by the concern filing the claim.

A typical sheet used by the Bureau of Aircraft Production in drawing up the summary of the claim is shown herewith. This gives a clear idea of some of the matters considered in making adjustments.

All Adjustments Soon Made

It will not be long, perhaps the middle of summer at the latest, when all the adjustments have been made, and the money which is tied up at present will have been paid out. It is certainly true that during this interval the industry is going to suffer. The reason is not far to seek. This delay and suffering would never have occurred had cost-keeping been thorough and complete in all instances. It would not be too much to say that the Government should work out a standard cost system to be used in connection with Government contracts hereafter, and to keep this knowledge filed

Equal Representation in Management Offered Harvester Employees

Workers to Elect Representatives to Meet with Equal Number Representing Employers, to Solve All Problems of Labor

[*As* AUTOMOTIVE INDUSTRIES *was going to press a telegraphic dispatch from Chicago stated that the workers in* 14 *out of* 17 *American plants and in all three Canadian plants decided by majority vote Wednesday to adopt the Harvester plan. The three plants where approval was not given by the workers were the McCormick Works, the McCormick Twine Mill and the Tractor Works, all on Chicago's West Side.*]

PLAN OF GREAT IMPORTANCE AND SPECIAL SIGNIFICANCE

THE plan of the International Harvester Co., which is given below, is of great importance and of special significance to the manufacturer in the automotive field because the International Harvester Co. is the largest concern having business of a similar character to that of other automotive manufacturers, at least in some departments, and because of the fact that, conditions being similar in many of the shops, the form of organization has a particular significance for other manufacturers in this field.

The form of organization itself is very interesting and is very similar to the forms of organizations adopted by some of the steel companies, oil companies and other manufacturing cooncerns which have been considered in these columns in previous issues.

It will be noted that in some respects it is a much simpler form than the organization adopted by concerns like the Colorado Fuel & Iron Co., and it avoids two of the difficulties with such organization plans.

It does not make any discrimination between the worker who is paid a salary and the worker who is paid by the hour.

It makes the logical and proper distinction between those who have supervision and those who do not.

It also provides for a simpler form of judicial procedure and this is a very great advantage.

The plan is well worked out but space will not permit of a lengthy discussion of it and this will be deferred to a later issue.

We recommend it to the very careful and studious consideration of all manufacturers in this field because of the special bearing which it has to the manufacturing conditions in this field and also because of the clear character and purpose of the organization. —*Harry Tipper.*

CHICAGO, March 11—The International Harvester Co. has to-day asked its 30,000 employees to vote on whether they want to have equal representation in the consideration of all questions of policy relating to working conditions in the different factories, measures for the improvement of health, steps for educational improvement, and all other factory matters of similar nature where there is a mutual interest between the employees and the employer or the management.

The scheme is an Industrial Council form of organization in which a Works Council is the major body. This Works Council is made up of equal representation from the management of the Harvester company and the factory workers. The factory workers elect by secret ballot what is known as Employee Representatives, in the ratio of one such representative for each 200 to 300 workers.

The management appoints what it calls Employee Representatives which in the Works Council are equal in number to the representatives of the factory employees.

This Works Council shall never have less than five employee representatives and a similar number of management representatives. Both of these groups of representatives shall have equal voice and voting power in all matters brought before the Works Council.

Should the Works Council not be able to reach an agreement on any questions before it then the matter is referred to arbitration. No such question can be referred to arbitration unless by mutual agreement of the factory representatives as well as the management representatives. When it is agreed that a matter has to be arbitrated upon the Works Council proceeds to agree upon an arbitrator. In case they cannot agree upon such an arbitrator then the employee representatives select one and

the president selects another. If these two agree their decision shall be final. If they cannot agree they select a third arbitrator and the decision of the three shall be final.

All employees who are working in any factory shall have the right to vote for the election of employee representatives from that factory. Nominations for employee representatives will be made four days before voting. Employees will vote by ballot. All employees both men and women shall be entitled to vote except foremen, assistant foremen, and other employees having the power to employ or discharge workers.

Whenever employee representatives have to journey to other cities to take part in the Works Council their traveling and maintenance expenses will be cared for by the International Harvester Company.

The underlying principle of the movement is to secure equal representation between the plant management and the plant employees and thereby do away with the arbitrary power of the managment.

Whenever there are matters affecting several factories the president, Harold F. McCormick may summon what is designated as a general council. This would be made up of employee representatives from the different Works Council, there being a Works Council for each factory. There shall be one representative of the workers in the general council for each 1000 of employees or a major fraction thereof and no factory shall have less than two representatives in a general council.

In a general council the management shall appoint a number of representatives equal to that of the employees.

The president or some person designated by him shall act as chairman of the general council but he shall not have voting power.

Organization of International Harvester Industrial Council

Article I. Purpose:

The employees and the management of the International Harvester Co. and its subsidiary companies undertake by the adoption of this plan of an Industrial Council to establish these relations upon a definite and durable basis of mutual understanding and confidence.

To this end the employees and the management shall have equal representation in the consideration of all questions of policy relating to working conditions, health, safety, hours of labor, wages, recreation, education and other similar matters of mutual interest.

Article II. Works Councils:

As the principal means of carrying this plan into effect, there shall be organized, at each Works adopting the plan, a Works Council composed of representatives of the employees and representatives of the management. The employee representatives shall be elected by the employees. The management representatives shall be appointed by the management, and shall not exceed the employee representatives in number. Both shall at all times have an equal voice and voting power in considering matters coming before the council.

Through these councils any employee or group of employees, or the management, may at any time present suggestions, requests or complaints, with the certainty of a full and fair hearing. Matters which cannot be thus disposed of may, by mutual consent, be submitted to impartial arbitration as hereinafter provided.

Article III. Department of Industrial Relations:

To aid in carrying out this plan the company has established a Department of Industrial Relations which is charged with the duty of giving special attention to all matters pertaining to labor policies and the well-being of the employees.

Article IV. Voting Divisions:

The basis of representation shall generally be one employee representative for each two hundred to three hundred employees, but in no case shall there be less than five employee representatives in the Works Council.

In order that the different departments and crafts may be fairly represented, each works shall be divided into Voting Divisions, and each division shall be assigned its proper number of representatives, based upon the average number of persons employed therein during the month of December preceding the election.

The Works Council may change the Voting Divisions whenever necessary to secure complete and fair representation.

Article V. Qualifications of Employee Representatives:

1. To be eligible for nomination as employee representative from any Voting Division the employee must be employed therein.
2. Foremen, assistant foremen, and other employees having the power of employment or discharge, shall not be eligible for nomination.
3. Only employees who are citizens of the United States, twenty-one years old or over, and have been continuously in the works' service for one year immediately prior to nomination, as shown on the records of the employment department, shall be eligible for nomination as employee representatives.

Article VI. Nomination and Election of Employee Representatives:

1. Nomination and election of employee representatives shall be by secret ballot. The first nomination and election shall be held as soon as practicable after the adoption of this plan, at which time the full number of employee representatives shall be elected.
2. At the first meeting of the Works Council the employee representatives shall be divided by lot into two classes, one-half with terms expiring on Jan. 1, 1920, and the other half with terms expiring on July 1, 1920. Thereafter the election of employee representatives of the first class shall be held in December and of the second class in June. Except as above provided, all employee representatives shall hold office for one year and until their successors are duly elected.
3. Notice of the time appointed for nominations and elections shall be given by bulletins posted publicly in the works at least two days before the date set for the nominating ballot.
4. All employees, both men and women, shall be entitled to vote, except foremen, assistant foremen, and other employees having the power of employment or discharge.

Nominations

5. Nominations shall be made in the following manner: Not more than four days before the date fixed for the election, a nominating vote shall be taken. A blank ballot stating

the number of representatives to be nominated from his Voting Division will be offered to each employee present at work on the date of the nomination, including all workers on the night turn, if any.

6. On this ballot the employee will write (or he may have a fellow employee write for him) the name of the person he desires to nominate. If his Voting Division is to elect one representative then one name shall be written on the ballot; if his Voting Division is to elect two representatives then two names, and so on.

7. Any ballot containing more names than the number of representatives to be elected from that Voting Division shall not be counted.

8. Employees will deposit their ballots in a locked box carried by a teller representing the employees, who shall be accompanied by a timekeeper.

9. When all who desire have voted, the timekeeper and two employee watchers shall open the ballot box and count and record the votes, in the presence of the works auditor, or person designated by him.

10. In Voting Divisions from which *one* representative is to be elected, the *two* persons receiving the highest number of votes shall be declared nominated. If any Voting Division is to elect *two* representatives, then the *four* persons receiving the highest number of votes shall be declared nominated, and so on.

11. If any person nominated is disqualified under the provisions of Article V, then the properly qualified candidate receiving the next highest number of votes shall be declared the nominee.

12. The results of the balloting and the names of the nominees shall be posted in the works as soon as the votes have been counted and the nominations declared.

Elections

13. Not more than four days after the nominations are posted, the election by secret ballot shall be held in the same manner as for nomination, except that at the *election* only the names of the persons who have been duly nominated shall appear on the ballots, and these persons alone can be voted for.

14. The name of the nominee receiving the highest number of votes shall be placed first upon the election ballot; the name of the nominee receiving the next highest number shall be placed next on the election ballot, and so on.

15. At the election the candidate or candidates receiving the highest number of votes in his or their Voting Division shall be declared elected members of the Works Council.

Article VII. Appointment of Management Representatives:

Upon the election of the employee representatives the management will announce the appointment of the management representatives in the Works Council, whose number shall in no case exceed the number of elected employee representatives.

Article VIII. Vacancies in the Works Council:

1. If any employee representative leaves the service of the works, or becomes ineligible for any of the reasons stated in Section V, or is recalled, as provided in Section IX, or is absent from more than four consecutive meetings of the Works Council without such absence being excused by the Council, his membership therein shall immediately cease.

2. All vacancies among the employee representatives shall be promptly filled by special nomination and election, conducted under the direction of the Works Council in the same manner as regular nominations and elections. Vacancies among the management representatives shall be filled by appointment by the management.

Article IX. Recall of Employee Representatives:

1. If the services of any employee representative become unsatisfactory to the employees of the Voting Division from which he was elected, they may recall him in the manner herein provided.

2. Whenever a petition is filed with the Chairman of the Works Council, signed by not less than one-third of the employees of a Voting Division, asking for the recall of their representative, a special election by secret ballot shall be held in that Voting Division under the direction of the Works Council, to decide whether such representative shall be recalled or continued in office.

3. If at such election a majority of the employees in the Voting Division vote in favor of recalling their representative, then his term of office shall immediately cease; otherwise he shall continue in office.

4. Any vacancy so created shall be immediately filled by a special election, as provided in Section VIII.

Article X. Organization and Meetings of the Works Council:

1. The manager of the Department of Industrial Relations or someone designated by him, shall act as chairman of the Works Council. A secretary shall be appointed by the superintendent of the Works. Neither the chairman nor secretary shall have a vote.

2. A majority of the employee representatives, together with a majority of the management representatives, shall constitute a quorum, and no business shall be transacted at any meeting where less than a quorum is present.

3. The Works Council may appoint such sub-committees as it deems desirable for efficient conduct of its business. On all such sub-committees both the employees and the management shall be represented, and each group of representatives shall have equal voting power.

4. The Works Council shall hold regular monthly meetings at times fixed by the Council. Special meetings may be called on three days' written notice by the chairman, secretary, or any three members of the Council. Sub-committees shall meet whenever necessary.

5. The company shall provide at its expense suitable places for meetings of the Works Council and its sub-committees and the employee representatives thereon.

6. Employees serving as members of the Works Council shall receive their regular pay from the company during such absence from work as this service actually requires, except that if the employee representatives so desire, they shall be at liberty to arrange for compensation to be paid by pro rata assessment among the employees.

7. Employees attending any meeting at the request of the Works Council or any sub-committee shall receive their regular pay from the company for such time as they are actually and necessarily absent from work on this account.

8. The Works Council may prepare and distribute to the employees reports of its proceedings, and the expense thereof shall be borne by the company.

Article XI. Duties and Powers of the Works Council:

1. The Works Council may consider and make recommendations on all questions relating to working conditions, protection of health, safety, wages, hours of labor, recreation, education and other similar matters of mutual interest to the employees and the management. It shall afford full opportunity for the presentation and discussion of these matters.

2. The Works Council may on its own motion investigate matters of mutual interest and make recommendations thereon to the Works Management; and the management also may refer matters to the Works Council for investigation and report.

3. The Works Council may confer with the superintendent or other person designated by him in regard to all matters of mutual interest, and shall receive from the management regular reports in regard to accident prevention, sanitation, restaurants, medical service, employment, educational programs and recreational activities, including information as to the cost, efficiency and results obtained.

4. The Works Council shall be concerned solely with shaping the policies of the company relating to the matters heretofore mentioned. When the policy of the company as to any of these matters has been settled, its execution shall remain with the management, but the manner of that execution may

at any time be a subject for the consideration of the Works Council.

Article XII. Procedure of Works Councils:

1. Employees desiring to bring any matters before the Works Council may present these to the secretary of the council either in person or through their representatives. It shall be the secretary's duty first to ascertain whether the matter has been properly presented through the regular channels to the superintendent, and if not he shall see that this is promptly done.

2. If the matter is not satisfactorily disposed of in this manner, the secretary shall submit a written statement of the matter to each member of the Works Council at least three days before the next regular meeting.

3. Any employee or group of employees thus referring a matter to the Works Council shall have an opportunity to appear before it and present the case. Any such group of employees shall select not more than three spokesmen from their own number to appear before the council.

4. The Works Council may call any employee before it to give information regarding any matter under consideration. The Works Council, or any sub-committees appointed by it for that purpose, may go in a body to any part of the plant to make investigations.

5. After complete investigation and full discussion of any matter under consideration by the Works Council, the chairman shall call for a vote, which shall be secret, unless otherwise ordered by the Council. The employee representatives and the management representatives shall vote separately. The vote of a majority of the employee representatives shall be taken as the vote of all and recorded as their unit vote. Similarly, the vote of a majority of the management representatives shall be taken as the vote of all and recorded as their unit vote.

6. Both the employee representatives and the management representatives shall have the right to withdraw temporarily from any meeting of the Works Council for private discussion of any matter under consideration.

7. When the Works Council reaches an agreement on any matter, its recommendation shall be referred to the Superintendent for execution, except that if the Superintendent considers it of such importance as to require the attention of the general officers, he shall immediately refer it to the President of the International Harvester Company, who may either approve the recommendation of the Works Council and order its immediate execution by the Superintendent, or proceed with further consideration of the matter in accordance with Article XIII.

8. In case of a tie vote in the Works Council, it shall be in order to reopen the discussion, to offer a substitute or compromise recommendation, on which the votes shall be taken in the same manner as above provided.

Article XIII. Reference to the President:

1. If after further consideration, the vote in the Works Council remains a tie, then the matter shall, at the request of either the employee representatives or the management representatives, be referred to the President of the International Harvester Company.

2. The President, or his specially appointed representative, may confer with the Works Council as a whole, or any subcommittee thereof, or any group of employee representatives, at such time and place and in such manner as in his opinion will best serve to bring out all the facts of the case.

3. Within ten days after the matter has been referred to him, the President shall either

(a) Propose a settlement thereof; or

(b) Refer the matter directly to a General Council to be formed as provided in Article XIV.

4. If the settlement proposed by the President is not satisfactory to a majority of the employee representatives, and if after a further period of five days no agreement has been reached, then the President may, if he deems it advisable, refer the matter to a General Council to be formed as provided in Article XIV.

5. If the President decides not to refer the matter to a General Council, or if the vote of the General Council is a tie, then the matter may, by mutual agreement of the President and a majority of the employee representatives, be submitted to arbitration, as provided in Article XV.

Article XIV. General Council:

1. Whenever in the opinion of the President any matter coming before any Works Council affects other Works of the company, or whenever he desires to refer any matter as provided in Article XIII, he may call a General Council to consider such matter, and thereafter the Works Council shall take no further action thereon.

2. The General Council shall be formed in the following manner: The President shall issue a notice designating the several Works which he deems jointly interested. Thereupon the employee representatives in the Works Council at each of the Works designated shall select two or more of their own number to act as members of the General Council. There shall be one such member of the General Council for each 1000 employees or major fraction thereof, except that no works shall have less than two representatives in the General Council.

3. The management representatives in the General Council shall be appointed by the President and shall not exceed the number of employee representatives.

4. The President or some person designated by him shall act as chairman of the General Council, without vote.

5. The first meeting of the General Council shall be held within ten days after the President's notice calling such Council.

6. The General Council shall, when necessary, take recesses in order to allow employee representatives therein to confer with other members of their Works Councils. For this purpose special meetings of the Works Councils as a whole, or of the employee representatives alone, shall (at the request of the employee representatives serving on the General Council) be convened at the respective Works, and full opportunity shall be given for conference and discussion with such representatives regarding their attitude and action on the pending matter.

7. Reasonable traveling expenses, including hotel bills of employee and management representatives serving on a General Council, shall be paid by the company.

8. The procedure in the General Council with reference to the consideration of matters coming before it and the manner of voting shall be the same as that prescribed for the Works Council.

9. If the General Council is unable to reach an agreement as to any matter, it may, by mutual agreement of a majority of both the employee representatives and the management representatives, be submitted to arbitration.

Article XV. Arbitration:

1. Whenever the President and a majority of the employee representatives in the General Council, or the Works Council, as the case may be, have mutually agreed to submit a matter to arbitration, they shall proceed to select an impartial and disinterested arbitrator. If they cannot agree upon an arbitrator, then the employee representatives shall choose one such arbitrator and the President shall choose another, and if these two agree their decision shall be final. If they do not agree, then they shall select and call in a third arbitrator, and a decision of a majority of these three shall be final.

2. The arbitrator or arbitrators shall be furnished all the information and testimony they deem necessary regarding the matter in arbitration.

Article XVI. Decisions of General Council or by Arbitration:

All decisions of any General Council or of any arbitrator or arbitrators shall be binding upon all the Works originally designated by the President as being jointly interested. Any such decision may be made retroactive.

Article XVII. Guaranty of Independence of Action:

Every representative serving on any Works or General Council shall be wholly free in the performance of his duties as such, and shall not be discriminated against on account of any action taken by him in good faith in his representative

capacity. To guarantee to each representative his independence, he shall have the right to appeal directly to the President for relief from any alleged discrimination against him, and if the decision of the President is not satisfactory to him, then to have the question settled by an arbitrator selected by mutual agreement.

Article XVIII. No Discrimination:

There shall be no discrimination under this plan against any employee, because of race, sex, political or religious affiliation or membership in any labor or other organization.

Article XIX. Decisions Affecting Wages:

Decisions affecting wages made by any Works Council or General Council or by arbitration shall be subject to revision whenever changed conditions justify, but not oftener than at intervals of six months.

Article XX. Amendment or Termination of Plan:

1. This plan may be amended by the Works Council of any Works by a majority vote of all the duly elected employee representatives together with a majority vote of all the management representatives. Amendments must be proposed in writing at a regular meeting, and no vote shall be taken thereon until the regular meeting following such presentation. No amendment shall be adopted that will destroy or limit the equal voting power of the employee representatives and management representatives in the Works Council and General Council.

2. If in the judgment of the President any proposed amendment affects other Works, then he shall call a General Council to consider such amendment. The adoption or rejection of an amendment shall not be the subject of arbitration.

3. This plan may be terminated, at any Works, after six months' notice, by a majority vote of the employees of that Works, or by action of the Board of Directors of the company.

Adoption of Plan

This plan shall become effective at any Works upon adoption by a majority vote of the employees of such Works voting thereon at a special election held for that purpose.

Inadequate Cost-Keeping Retarding Adjustment

(*Continued from page* 563)

away for future use. What is true in Government work is true to a lesser but not insignificant degree in commercial life. Cost keeping must be put on a higher plane than ever before if general business is to be kept stable.

The situation in other districts exactly parallels that of the Detroit district. There has been held at Washington a meeting of the representatives of the districts Ordnance offices, for the purpose of planning to speed up the settlement of contract claims. It was brought out that less than 25 per cent of the expected number of ordnance claims have been presented to the district claims boards by contractors, to date. The district chiefs advised that the delay results from the magnitude of the work involved in setting up the claims which entail the taking of complete inventories of materials and supplies, determining the liability of the contractors to their sub-contractors and supplies of material.

All district chiefs present were urged by war department officials to use every effort to speed up the work of settling claims of contractors in order to relieve, so far as possible, the unemployment situation, and advised to use all means possible to bring financial relief to sub-contractors where payments are being delayed by the preparation of claims of prime contractors.

The Cleveland district office reported that seventy-two claims have been presented to it up to last week; that awards have already been made or are ready to be made in a majority of these, and that most of the remaining claims are expected to be presented by contractors within the coming two weeks.

Practically the entire staff of the Cleveland Ordnance district is now devoted to checking and expediting settlement of ordnance contractors' claims, and the contractors and sub-contractors are finding it highly advantageous to consult with the district claims board in setting up their claims resulting from cancellation or suspension of contracts.

The Wallis tractor exhibit at the Kansas City tractor show was an excellent example of manufacturers' merchandising. The chassis showed most parts exposed and there was a goodly display of components

Export Managers Enthusiastic

Optimism the Keynote of Well-Attended N.A.C.C. Convention —Plans for Combinations Under Webb Law Outlined —Importance of Proper Packing

THAT the United States has been a slumbering giant in the matter of export trade was the thought which dominated J. Walter Drake's introductory address at the Export Managers' Convention of the N.A. C.C., held last Friday in New York. He said, in effect, that an academic view of our country's present position in relation to the development of overseas business was not an ideal way of looking at things and that our future in foreign trade called for constructive and eminently practical action if we were to hold the markets we have gained and get back those we have lost owing to war conditions.

"Keep our ideals high and our hands clean," said Mr. Drake, who then went on to state that our industry's history during the 4 years of war had indelibly stamped it as the real leader in foreign trade and that it was up to the automotive export men to maintain the highest level of commercial integrity in our relations with our foreign customers in order to consolidate our future on a permanent basis.

He pointed out that history-making events now taking place in Europe would probably lead to new relationships as between ourselves and other countries, to new associations of both economic and social trends and that it was imperative that we realize to the full those differences in manners and customs which constitute (if ignored) the chief difficulty in the conduct of successful business.

Mr. Drake added that we had a vast inland population which did not always realize the magnitude of our overseas possibilities in relation to the expansion of our trade and that in his opinion the automotive industry was so organized that in future it would point the way to other branches of the country's commerce in the development of a general foreign trade of practically limitless extent.

Mr. Drake also touched upon the evident reluctance of factory executives to accept statements from their export departments as to differences and refinements demanded by buyers in various foreign countries; that this was a condition which demanded careful attention and prompt remedying; and that although the problem might be easy to the larger manufacturer it was not always such a simple matter for the smaller factory.

He emphasized that the success of our export trade called for co-operation in service to an extent which would enable the smaller maker to enter the field on terms of equality with his bigger competitor, remarking that the factory which exports 5000 cars a year benefits by the competition of the maker who exports 5 in the same period on the broad principle that America must advertise America overseas.

Export Epigrams

The United States has been a slumbering giant in the matter of export trade.—Drake.

No Orphan Annies should be permitted to compete with our standard automotive products in foreign countries.—McElwee.

European tariffs and embargoes are a temporary fence which will be pulled down as soon as demobilization is effected and normal commercial conditions have been restored.—Domeratsky.

The big commercial mind is beginning to realize that unless the community is served trade relationships abroad cannot endure.—Walker.

Keep our ideals high and our hands clean.—Drake.

The world is an expanded home market—don't conduct your foreign trade differently from your domestic business except those modifications necessary to meet foreign conditions.—Walker.

We must so establish ourselves in the foreign markets that the consumer will not realize the fact that our products had their manufacturing origin 5,000 miles away. We must give adequate and prompt service.—McElwee.

Alfred Reeves stated that at the present time the Export Committee of the N.A.C.C. was actively engaged in conjunction with the authorities in Washington on the subject of taxation and that although at this time nothing definite could be said regarding taxation on exports, yet the whole thought lying behind the new measure was that there would be no tax imposed on cars exported either direct from the factory or sent abroad through export houses or shippers.

Within a few days it is expected that a primer covering the whole situation will be printed and distributed not only to manufacturers but to every internal revenue department in the country. This course has been adopted by the N.A.C.C. to obviate all possibility of misunderstanding as to the actual conditions.

Roy S. McElwee, assistant chief of the Bureau of Foreign and Domestic Commerce, in the course of his address made a number of pertinent suggestions dealing with the subject of service in foreign countries. He pointed out that a fundamental principle to be observed, if the United States is to maintain its present position of the leading exporter of the world, was that of rendering adequate and prompt service at least equal to that afforded by foreign manufacturers.

He gave concrete instances of his personal experiences in handling agricultural machinery and emphasized that the primary mission of the American automotive manufacturer was to establish himself in the foreign mar-

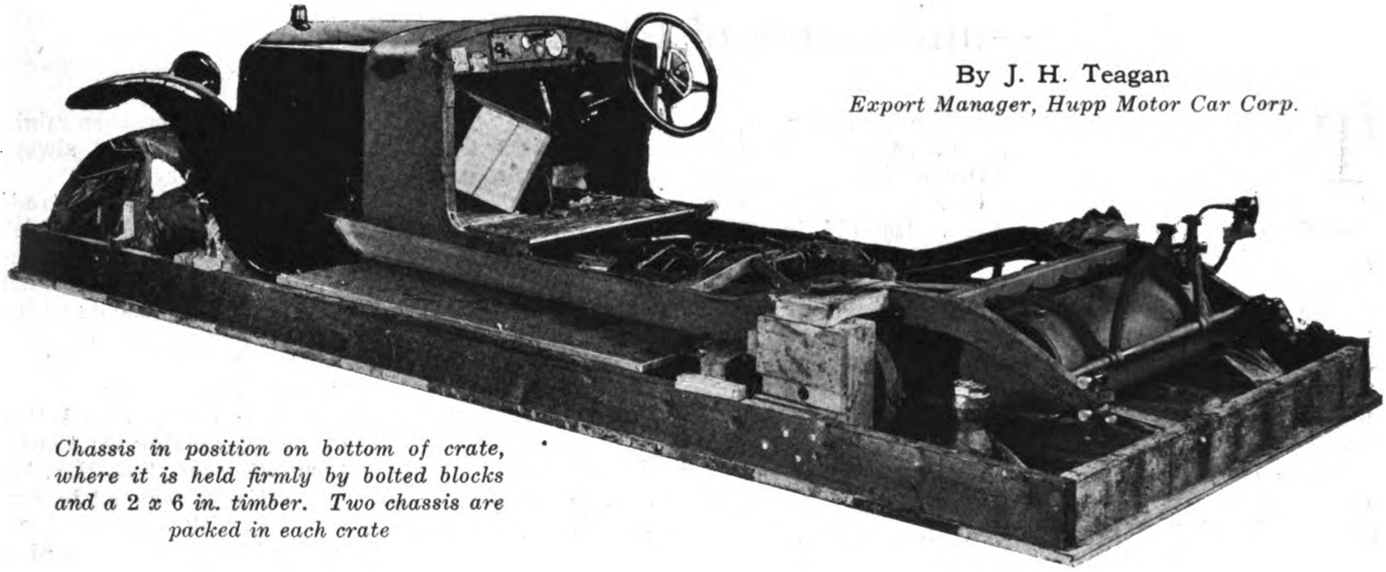
Crating Automobiles for Export*

Demonstrating How Absolute Security Combined with Minimum Waste of Space May Be Attained



By J. H. Teagan
Export Manager, Hupp Motor Car Corp.

Chassis in position on bottom of crate, where it is held firmly by bolted blocks and a 2 x 6 in. timber. Two chassis are packed in each crate

AMERICAN manufacturers have in the past been criticised for their methods of packing and crating exported commodities, and American methods have been compared adversely with those of competing foreign exporters, indicating that customers abroad find our methods far from satisfactory. It seems to me that this question is so important to all exporters that a discussion of our methods and a free interchange of ideas and suggestions, tending to improve these conditions, should be of interest to the manufacturers represented at this meeting.

If American manufacturers expect to maintain their positions as exporters, they must study the requirements of their customers, and endeavor, if possible, to satisfy those requirements, going as far or farther than competitors in other countries. American goods of every kind must be at least as satisfactory in quality, as reasonable in price, as well delivered, and the customer's good-will as well guarded as is the custom of our competitors.

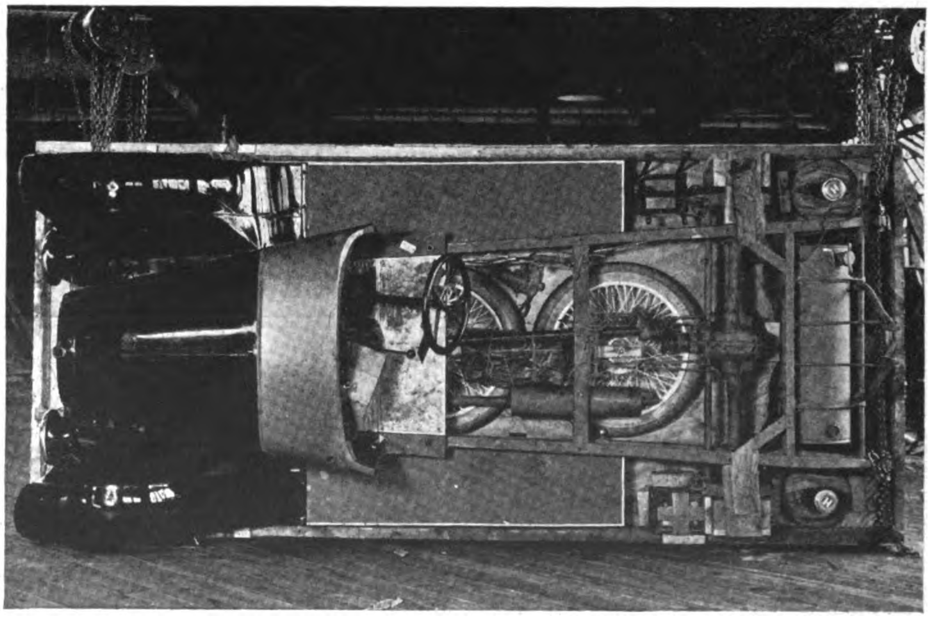
At our factory we have experimented with different types of crates, covers, paper packing and rust preventives. We have been helped by suggestions from our foreign customers and travelers, and by our study of the methods of other manufacturers of automobiles and commodities. We are still far from satisfied, but do know that our efforts have resulted in a great improvement and that customers abroad speak of it.

As the customer is charged for crating, it is essential that we keep the cost as low as it is possible and still insure the safe, undamaged arrival of the goods.

The following is the method which we have adopted. It is better than any other which we have tried, and protects our car from dust, water and damage by the elements or rough handling. Reports indicate that goods packed in this way are reaching our customers in as good condition as they left the factory.

Immediately after the car has been tested and washed it is driven onto the crating room floor, where we immediately apply to all nickel parts a rust preventive, and for this purpose we have been using a liquid called Corol. This, we believe, is the best rust preventive for nickel parts that can be found, and is easily removed. The British Government approved Corol after a very careful investigation, and specify it to be used on all of their shipments.

After the application of Corol the car is driven onto the bottom section of the crate. Surrounding this section are the

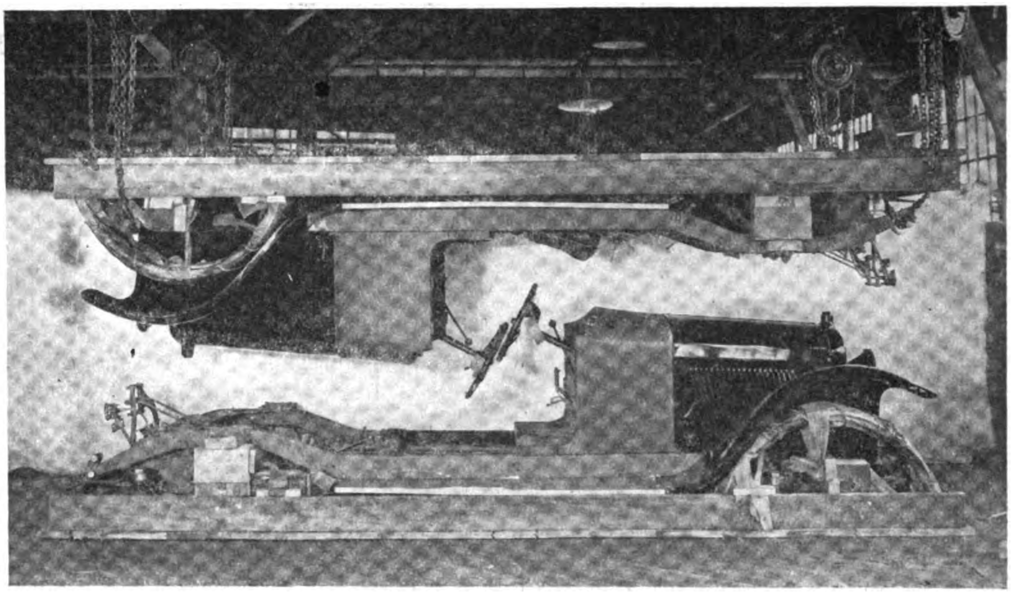


This illustration gives a good idea of how every available inch of space is utilized. This is of primary importance, as freight is charged by cubic feet

*Paper read before Export Managers' Convention, New York, March 7.

side sections and top of the crate. As the car is disassembled the parts are laid in position on the side and top sections of the crate. I emphasize this, as so often parts are taken from the car and mislaid and not put in the crate with the original shipment. Placing all the parts removed on the sections of the crate has eliminated most of this trouble.

The car is suspended by means of chain falls. Wheels, windshield and top are removed. The top carefully wrapped in burlap and fastened to the top section of the crate, directly over the position of the engine. The windshield is crated in a small box and fastened to the top section of the crate, immediately over the tonneau. Two wheels are fastened to each side section of the crate. They are secured with half-inch bolts.



Showing the method by which the chassis secured to the top of the crate is lowered into position before the ends and sides are attached

The steering post is dropped. Shackle bolts are removed and springs are compressed and held in this compressed position by means of metal straps. Brake rods are unfastened at one end and the loose end tied with burlap to the propeller shaft. This, you will readily see, makes a very compact package and reduces the cubic feet required.

The spark plugs are all removed, carefully and thoroughly oiled, placed in a leather bag and fastened to the control levers. The spark plug holes in the top of the cylinder block are tightly corked.

All of the oil is thoroughly drained from the car, also all gas and water, and the water inlet hose is disconnected at one end to insure the thorough drainage of the radiator. This prevents the dealer, when the car is reassembled, forgetting to fill the radiator.

The motor and all mechanical parts are sprayed with a mixture composed of vaseline and gasoline, which acts as a rust preventive and is easily removed. At one time we even coated the cylinder walls with a heavy oil, but this has not been found necessary and has been abandoned.

While the car is still suspended, we fasten over each rear axle spindle a 5 x 10-in. block, which has a hole bored in the center, and a 6 x 6-in. block over each of the front axle spindles. The car is then lowered to set on the bottom section of the crate, and the blocks over the axles are securely fastened. A 2 x 6-in. timber is then fastened to the tops of these blocks, which acts as a wedge from the frame to the side of the case, preventing the car from moving about, regardless of the position in which the crate may be placed.

We have found that if the car is securely fastened in this way the crates can be loaded, setting on the narrow side, and permitting four crates on the platform on a small freight car, thus obviating decking one machine over the other.

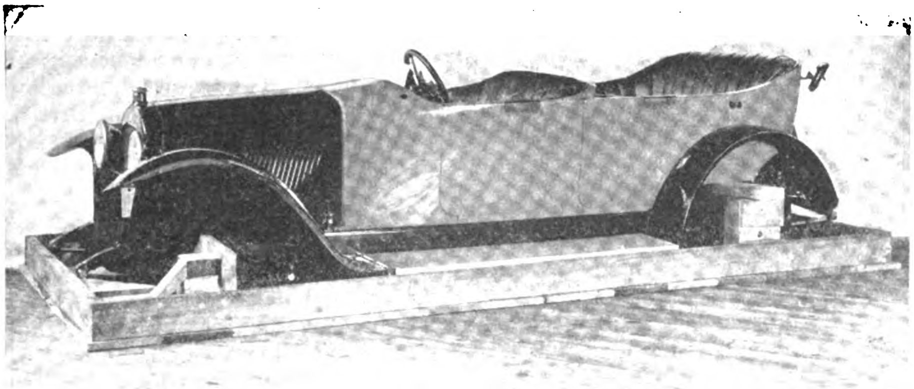
The car and parts being now securely fastened to the sections of the crate, the sides and ends of the crates are placed in position and the top section mounted, securely nailed and ready for loading.

We make our crates of 1½-in. tongued and grooved lumber, selecting the best possible quality, free from knots. This lumber is used for the top, bottom, ends and sides, braced by crosspieces, 2 x 6-in. timbers. The inside of the crate is completely lined with Kraft waterproof paper. Formerly, in addition to lining the box, we covered the car with a Safepack paper envelope and also covered the crate, after loading on flat cars, with a waterproof paper. With the type of crate outlined these last two precautions seem unnecessary.

We ship two chassis packed in one crate, fastening one to the floor section of the crate and the other to the top section. When chassis are shipped the wheels are fastened underneath the chassis.

We have tried to compress our shipments into the smallest possible crate and now cannot find any further way to reduce the dimensions, there being only ⅛ in. between the high point in the automobile and the top sections. The bottom of the differential gear housing comes within a fraction of an inch of the 1 x 6-in. timber which runs along the center of the bottom section. Only ¾ in. clearance is allowed between the edge of the fender and the side section, and less than that between the end of the springs and the timbers of the crate ends.

The question of crating cannot be given too much attention. It would seem to me that the aim of the export men should be to see that not only *their* cars, but all other cars, and all other products exported, are laid down at destination in such good order that no customer could ever complain of American methods, and I would suggest that a small committee be appointed to tabulate the methods used by various automobile manufacturers, asking each one freely to give all the information that he has regarding costs, and also any complaints or compliments that he may have from his customers regarding the method used. Copies of this tabulation could be sent to the various export managers and should result in improvements and possible economies to many of us.



Complete cars are packed singly and are held so securely that the crate may be placed on its side without damaging its contents

Suggested Combinations Under Webb-Pomerene Law

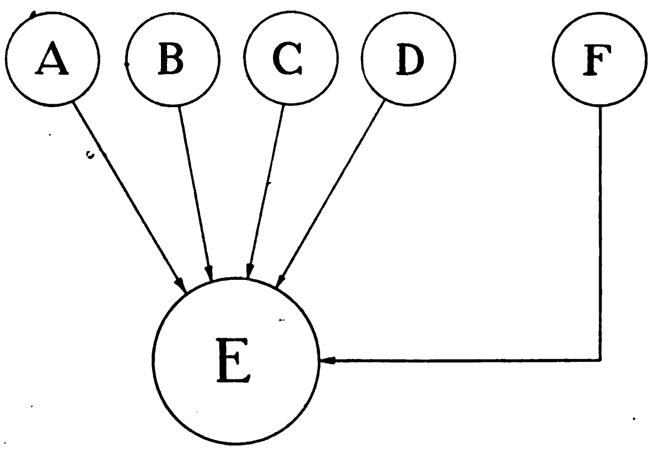


Fig 1—This represents the normal (and therefore ideal) form of combination for export.

A, B, C and D are four individual companies desirous of engaging in export trade under favorable conditions. They may be engaged in precisely similar business as in the case of the Copper Export Corp. or they may be engaged in non-competitive lines in the automotive industry.

These four companies form themselves into a single export association or corporation (E) which may either purchase the products of all outright and of itself accept all responsibility for the entire conduct of export business or it may be simply a unit selling organization acting in the interests of the four and taking instructions as to policy, etc., as applied to all.

It is conceivable that a fifth company (F) may desire to be associated in the benefits of the export association (E) to a limited extent and it would be permissible to so arrange matters that this fifth concern should retain its individuality to an agreed-upon extent, while it would be willing to come in line in matters applicable to all.

It is important to observe that the export association (E) may be only an agent or may be an outright purchaser of the combined products of A, B, C and D. If there should be an (F) it would be subject to terms to be agreed upon.

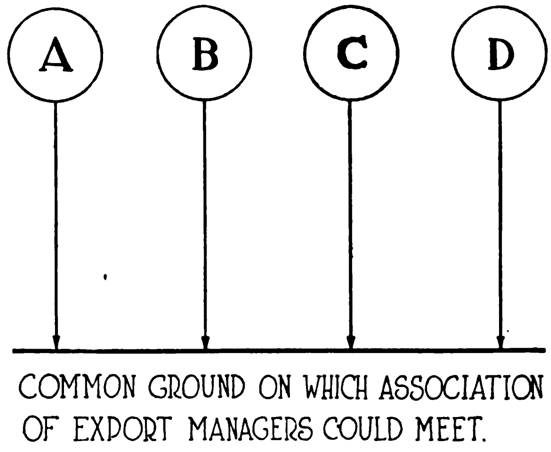

Fig. 2—In cases where the normal method of combination, as shown in Fig. 1, cannot be adopted owing to circumstances affecting the relative positions of the companies desirous of engaging in export trade, the following solution is suggested. It is understood that this method has been under consideration by the Federal Trade Commission and that they are inclined to agree that it offers a practical solution of what may be termed a half-way stage to a more permanent and unified plan.

Take four concerns, A, B, C and D, all of which have foreign connections and are at the present time engaged in export trade along lines or involving methods which are fundamentally different.

Assuming that it is impossible to unify the foreign business of these as in Fig. 1, it is suggested that the export managers of all four be formed into an unincorporated association registered in Washington.

This unincorporated association would be in a position to meet and agree upon co-operation in such matters as shipping, prices, joint stockrooms or anything else on which the four firms could have a common ground of operation.

This plan, while admittedly not perfect, would enable A, B, C and D to preserve their respective individualities, to avoid cut-throat competition and to effect considerable saving in expense in those matters which are common to all.

Export Managers Enthusiastic

(*Continued from page* 569)

ket as to make his customer unaware of the fact that his goods were manufactured 5000 miles away instead of just around the corner.

Mr. McElwee admitted that while such a proposition was a comparatively easy problem for the larger manufacturer, it was not quite so simple for the smaller exporter with relatively limited resources, and to overcome such a difficulty he suggested the possibility of co-operation between non-competitive lines in the matter of using a common stockroom for spare parts, sharing offices, etc., but maintaining individuality to a greater or lesser degree in the matter of sales methods if it were found impossible to do otherwise.

He insisted that "an embryo home office" was a primary necessity to the successful conduct of an export business, stating that even if such an office in Bordeaux, Marseilles, or elsewhere abroad simply consisted of a desk and a telephone it gave a sense of security to the purchaser. He said that such an office should be supplemented by the use of stationery bearing its address and that the adoption of such a course did not mean that the salesman had to stay indoors to answer calls so long as he could arrange for queries to be received and held for his attention.

Mr. McElwee spoke at some length on the absolute necessity of cars and trucks exported being representative of standard American practice and suitable for the purposes for which they were designed. He said, "No Orphan Annies should be allowed to compete with our standard products abroad. It is a case of the United States against the world, and an individual break-down means that every American product suffers by inference."

Louis Domeratsky of the Division of Foreign Tariffs of the Bureau of Foreign and Domestic Commerce announced his readiness to answer questions relating to the present position in regard to restrictions, tariffs, etc., and in response to many queries gave information which served to clear a number of debatable points. Obviously, there are many matters which are still in doubt, but the sum-total of Mr. Domeratsky's opinion was along the following lines:

Status of British Embargo Indefinite

It is impossible at this time to say anything definite regarding the British embargo, but it is evident that no country can maintain an embargo indefinitely. It may impose prohibitive import taxation or tariff. The British automotive industry, as also the French, considers it has claims on its government on account of war services rendered and that it merits a meed of protection.

It is believed that there is no restriction in either country on the importation of farm tractors. Tariffs are a temporary fence erected to stay only until demobilization has effected a return to normal conditions.

In response to questions, Mr. Domeratsky stated that his department experienced no reluctance on the part of foreign governments to give full information in regard to tariffs and restrictions.

Prefacing the remark by the statement that it was not an official statement, Mr. Domeratsky gave it as his

opinion that England was at the present time taking advantage of existing conditions to advance her theories on tariff reform and because of sentimental and perhaps political reasons. He added that it should not be forgotten that England was a commercial as well as a manufacturing country and that undoubtedly she would be glad to see the abolition of all restrictions affecting the import of foreign-made goods.

In response to a question, Mr. Domeratsky said that he could not give any information as to why it was possible to receive coded cables from England but impossible to send them from here. He also stated that while French tariffs applied to France's colonial possessions, Great Britain's tariffs did not apply to British colonies. A further question in regard to a possible list of present tariffs and restrictions was answered by Mr. Domeratsky referring the inquirer to a recent issue of AUTOMOTIVE INDUSTRIES in which complete data were published.

The matter of restrictions on car exports to Australia, where two chassis must be sent for each complete body exported, was raised. It was explained that this restriction was designed to encourage Australian body builders.

Mr. Domeratsky pointed out that in the event of stocks of parts being held at a free port, they could be shipped thence to any point, paying the duties called for at the ultimate destination but escaping intermediate duties in countries passed en route by being shipped through these in bond.

The Webb-Pomerene Law

Allen Walker and Gilbert H. Montague, both of whom assisted in the preparation of the act known as the Webb-Pomerene law, which provides for the combination of competitors for export selling, spoke at length on the advantages conferred on automotive manufacturers in the opportunity afforded under the new law to effect combinations for the purpose of conducting export business in a manner which simplifies operation, reduces expense and confers the full benefits of co-operation.

Mr. Walker outlined the main points of the law and mentioned the efforts which had been made by the Guarantee Trust Company to obtain commercial information sufficient to create a directory or "Who's Who" of foreign trade, a compilation which now contains 60,000 names and ratings.

He pointed out that trade combinations already effected had proved beyond the shadow of a doubt that all business conditions could be met and all problems solved irrespective of the apparent impossibility of adjusting conflicting interests where it was sought to associate large firms with an existing foreign trade connection with smaller concerns who had not engaged in overseas trade.

American manufacturers are forgetting petty differences, he said, and are getting together for the development of foreign trade on the general principle that nothing matters but the common good and that the community must be served if they are to succeed.

Mr. Walker instanced the British Empire League as an association termed to develop a bond of sentiment, to emphasize the fact that self-interest alone was useless when confronted by foreign trade conditions and to point out continuously that national pride in the Empire's products was an essential to successful export.

He said, in effect, that the shelves of the world were empty, that it was the time when we could perfect our plans for filling them and keeping them filled, and that the world should be considered simply as an enlarged home market where nothing need be changed in business methods except in so far as it might be necessary to meet a country's individual conditions, manners and customs. Mr. Walker mentioned that active steps had been taken to counteract propaganda having for its object misrepresentations of the real object of the Webb law in various foreign countries—notably in Latin America and Australia.

How Export Combinations May Be Effected

Gilbert H. Montague, who has been engaged in the formation of the Copper Export Corp. and a number of other combinations under the Webb law, spoke of the various ways in which complete or partial associations could be formed to carry on export business.

He referred to the fact that if circumstances did not seem to warrant a close combination where a number of firms pooled all their export interests through a single association and sold their products solely through that association, there were other ways of solving the problem.

He illustrated a few of the alternatives by means of diagrams, showing that it was possible to enter into export combinations in such a way as to preserve existing interests in the case of one or more of its members who might be in a better position to engage in export trade than were other individual members of the same combine, without injustice to any one of them and with marked advantages to all.

The principle upon which these combinations are being effected is that matters must be so arranged that no one member can lose the benefit of anything which has been done and that all shall gain the advantages of cooperation without losing their respective individuality.

Such matters as advantages conferred by factory location in relation to the seaboard whereby one member of an associated group would normally reap the benefit of lower freight costs and under the older conditions could cut prices on this account have been eliminated in favor of an averaged flat rate based on the cost of freight from all the factories in that particular combination.

Our New Ships

Ira A. Campbell, Admiralty Counsel, United States Shipping Board, spoke of what had been accomplished in the construction of new vessels, the acquiring of others, the difficulties of the past and the hopes for the future. Mr. Campbell did not make any statement regarding the actual number of ships available over the various trade routes for commercial shipments at the present time.

He outlined the number of vessels and the total tonnage available at the signing of the armistice, mentioned the tentative program which normally should have been in effect at the present time and stated that the Board's plans for the transfer of shipping to strictly commercial service had been completely upset by the European food shortage, which necessitated the diverting of much tonnage for the time being.

He referred to the possibilities of the future in reference to the ultimate ownership and operation of the now Government-controlled ships and made suggestions covering alternative methods of keeping them in effective service in advancing the export trade of the country.

Registration of Trademarks

James L. Steuart impressed upon the delegates the absolute necessity for protecting trademarks, pointing out that the law of the United States, where the adoption and use of a trademark gives right and protection, differs from that of foreign countries. Abroad, said Mr. Steuart, countries do not recognize such rights, but provide statutes permitting a manufacturer to apply for the

right to register a trademark—the first to register getting the right and protection.

He added that this state of affairs had caused much trouble and expense to American exporters owing to the facility with which a United States trademark could be registered abroad by anyone who thought he saw an advantage in controlling that trademark in a given country.

This practice has grown to such an extent that there have been cases where United States trademarked goods have been refused admittance at foreign ports on the application of some individual totally unknown to the manufacturer of those goods, but who had realized the opportunity for something little, if anything, short of blackmail. Mr. Steuart gave specific instances of hardships of this nature inflicted by piratical persons on American manufacturers and impressed on the convention the necessity for having trademarks protected abroad.

Foreign Selling Problems

George H. Smith, president of the American Manufacturers' Export Association, outlined the entire position of the United States manufacturer in relation to export trade and its possibilities, touching on the changed conditions and the keener competition which may be expected in the future.

"At the very outset," he said, "let me say that while the present obstacles to the development of our export trade are serious and real, there is not one which cannot be surmounted by the manufacturer who is determined to make export trade a definite and permanent part of his business.

"A great part of the world is laboring under a burden of debt and difficulty brought about by the war, but when readjustments are made (and they must be made quickly) there will be inevitably a tremendous demand for those American products which other countries must have if they are to win their way back to normal conditions.

"There is a responsibility as well as an opportunity for the American manufacturer in the field of foreign trade. The country is gradually beginning to realize that to maintain the production of the United States at its present high peak and to offer employment to the workmen of America, the nation must build up the permanent foreign markets which belong to it because of its natural aptitudes.

"The automobile manufacturer who has the courage and the energy to develop his foreign sales is, therefore, not only performing a service for himself, but by adding to the volume of his country's exports is performing a distinct economic service for his country."

Packing for Export

J. H. Teagan gave some practical advice on the subject of packing passenger cars for export as done by the Hupp Motor Car Corp. The address was highly instructive and the photographs which were passed around were examined with interest. As the subject is of general trade importance some of these photographs are reproduced, together with a synopsis of Mr. Teagan's talk, on pages 570 and 571.

Peter S. Steenstrup, general manager of the General Motors Export Co., pointed out that successful advertising methods abroad differ in important respects from the methods adopted with success in domestic advertising; that trade literature should be in the language of the country where it is circulated; and that the possibility of co-operative advertising by members of the N.A.C.C. should be considered.

Mr. Steenstrup referred to the fact that our whole-hearted participation in the war had given us a higher standing in the British colonies and in many other countries and that the present time was ideal to thoroughly establish ourselves in the overseas markets. He said: "The time to advertise is now, and the present unusual opportunities, if neglected, may never present themselves again."

All features of advertising were given full consideration, methods of placing overseas advertising were dealt with, suggestions on many points were made and in giving a list of American export journals which he described as "excellent mediums to reach overseas jobbers, dealers and agents," Mr. Steenstrup said: "There is but one American automobile trade publication with a large overseas circulation, *El Automovil Americano*, a quarterly published in Spanish by the Class Journal Co."

D. B. Richardson, foreign sales manager of the Studebaker Corp., made reference to the present popularity of the clincher type of tire in most foreign countries, a circumstance which he attributed to the early influence of the Michelin tire. The many advantages of the straight-side type were pointed out and it was suggested that both car and tire manufacturers co-operate to standardize the use of this type not only for the reason that it would be advantageous to both but that it would also confer an appreciable benefit on the user.

It was admitted that in Continental Europe there would be but little prospect of bringing this change about, but it was the opinion of the writer that it was quite practicable to standardize the straight-side tire elsewhere.

Right-Side Steering

Right-side steering is, in the opinion of Mr. Richardson, an essential for cars exported to countries where the rule of the road compels drivers to keep to the left. Under such conditions the difficulty of signaling an intention to turn is greatly increased by the use of left-hand drive and, as one of the delegates pointed out, the left-side location of the steering wheel may mean that a front-seat passenger has to alight in the roadway—possibly in mud—unless the driver first gets out and the passenger crawls under the steering post.

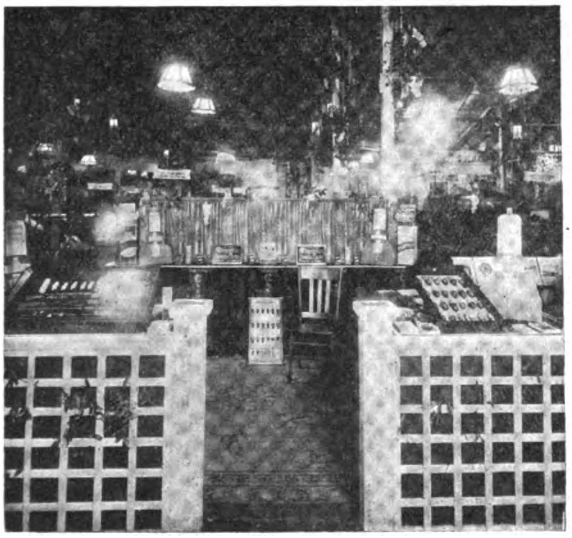
This paper concluded the regular session, but, in response to the request of the chairman, H. M. Robins of Dodge Bros. gave an interesting account of his impressions of the automotive industry gathered during a recent tour of England and France. C. J. P. Lucas, Chicago, spoke regarding the possibilities of railroad co-operation with exporters and referred to the fact that from March 15 both United States and Canadian railroads would issue through bills of lading, make out consular documents, etc., for any part of the world.

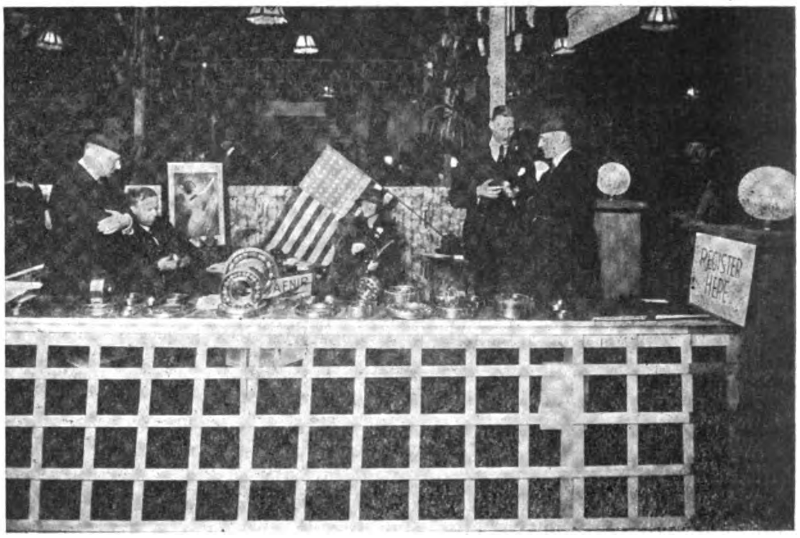
Light as Deteriorating Factor in Airplane Fabrics

SPEAKING before the Royal Aeronautical Society on the strength and deterioration of fabric and dope used for aircraft, Dr. F. W. Aston said that sunlight was the only serious agent in deteriorating the strength of doped and undoped linen aeroplane fabric. The change in rate of loss of strength was very great in summer and practically negligible in winter. Once the action of light was prevented, doped fabric was capable of sustaining continuous exposure for several years without dangerous weakening. Unprotected doped fabric lost about 12 per cent of its strength in a single average English summer day at sea level, and the rate was enormously greater at high altitudes above the clouds.

Rapid as the deterioration was in the case of an English machine, in the case of an enemy Albatross scout, captured practically brand new, it was even worse.

Good Exhibits at Kansas City Tractor Show

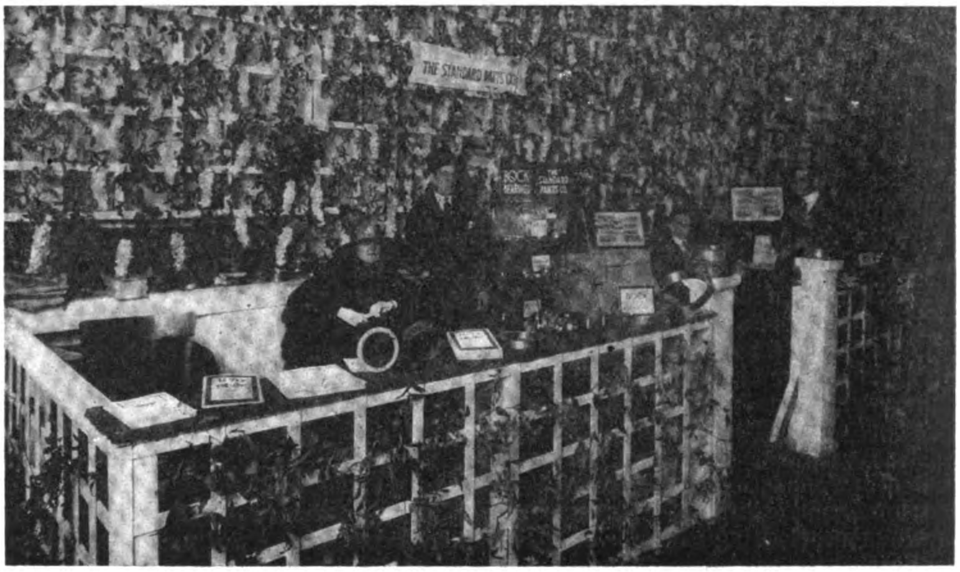


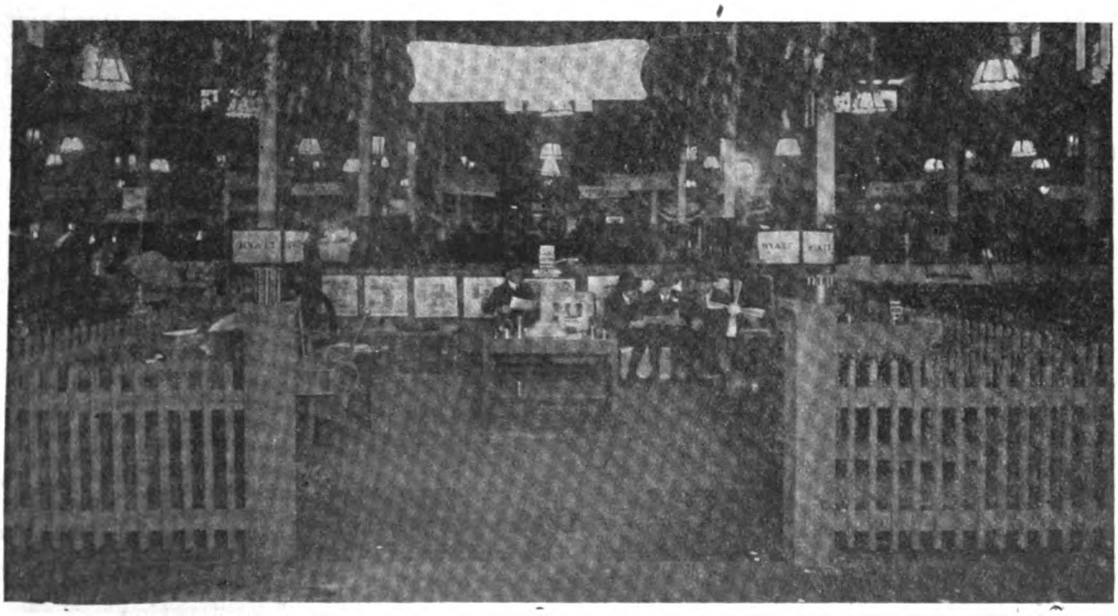


The Champion Spark Plug Co. is about the most show-going corporation in the business, and it always has a good exhibit. This set-up at the Kansas City tractor show is typical in that it has a Champion look

At the right of the Champion picture is the very good exhibit of the Fafnir bearing company. This was but one of many exhibits of the industry's best parts makers

And here is Standard Parts. With many others, it was alert to the opportunity of getting in touch with the growing tractor industry





Hyatt roller bearings had quite a lot of room, where interested engineers, farmers or any one else could come in and sit down and talk over the merits of the product. A place to sit down and talk is a big show asset

Egotism in Business a Grave Error

Consulting Engineer Can Help to Guide Executives Along Broader Lines of Progressive Thought—Quality the Eventual Criterion

By J. Edward Schipper

SELF-SUFFICIENCY is as bad for a business organization as it is for an individual.

It builds up a Chinese wall around the organization which eventually becomes fatal. Millions of dollars have been lost during the history of the industry because of this fault being carried to an excessive degree, and it is upon one of the most important methods of remedying this fault that the following observations are given.

We cannot see ourselves as others see us. Neither can we judge the product of our own hands and brains as others judge it. As every manufacturer knows, the history of his product has just begun when he has put an experimental model through its paces and finally puts it into production. It is the public or the consumer which must be the final judge.

If the public or consumer judges adversely, millions of dollars may be lost, or sums of money may be lost which are fatal to the success of the concern which loses it.

Influence of Public's Judgment

If the public judges favorably, then the opportunity is often open to fortune. It is true that the judgment of the public or consumer may be swayed by clever salesmanship and a trained and good sales organization, but even with this factor considered it is far easier for the salesman to sway the public in favor of something which is really good throughout than it is to attempt to put over a product which is weak in some vital feature.

It is a mistake for a manufacturer to attempt to bring out a new model along different lines from its predecessors without calling in the assistance of outside talent such as a consulting engineer or some advisory counsel.

Frequently our manufacturers rely too implicitly on their own engineers, expecting them to cover not only the entire field of design itself, but also to be able to project themselves into the future to the extent of knowing definitely the trend of engineering progress and the trend of popular demand.

The men who have a knowledge of both these phases of engineering work are rare indeed; in fact, it is questionable whether they exist.

A man who is thoroughly capable in detail design is rarely if ever capable of properly judging the commercial or sales angles which must always be considered in a new product. A man who designs the details of the engine knows little or nothing as a rule about the popular requirements in the line of appearance. Plant men as a rule are detail men.

The consulting engineer is a man who, being removed from the necessity of concentrating on particular details, has a wider vision and a broader aspect than the plant engineer. He should be called in to help paint the general picture of a design before the design ever gets any further than the drawing board. He should be fortified with such a store of engineering knowledge that he knows the weak and strong points of every kind of design, and will be able in advance to clear the way of troubles which are always sure to occur when a product is designed from the details out toward the finished product.

Too often the logical process of design is reversed and an automobile, for instance, will be built around an engine, or a truck will be built around an idea of spring suspension; and while the particular engine or the particular spring suspension may be the best in the world, there are too many instances where the vehicle as a whole has failed because the specialist failed to call in outside help to assist him maintain the proper balance between his own knowledge and what he has taken for granted from existing practice.

Probably never again will the automotive industry be in the condition that it is to-day. While on the surface there are many things which are disadvantageous, on the other hand we now have the opportunity for laying a foundation for future developments which will never come again. We have been given a fresh start and still are able to use the experience of past years.

One of the lessons that we should draw from this is that in the past we have not been particular enough as regards the quality of our products, but our industry taken as a whole has suffered the fault committed by many. It has been too eager for quick returns. If we have a national failing it is that we look for quick turnovers from our industrial projects.

Must Build for Quality

Rather than building for the permanency of a product, we have been building, in many cases, for the profits which could be extracted from the product within a few years. *One of the greatest means of combating this tendency is going to be in the use of men of broad vision and wide experience who can judge our products, not from the standpoint of how much money is going to be made on it, but from the standpoint of quality.*

The proper use of consulting engineers in this profession will do a world of good in creating new standards and higher planes of development for automotive products. A consulting engineer should not be called in solely in times of trouble. He should be called in more or less regularly on various lines of thought.

A consulting engineer should build up around himself a complete arsenal of engineering information as well as maintenance problems. Abroad there are many concerns of consulting engineers which are held in high esteem, and with the size of the industry in this country there should be many such who would be in a position to do the industry a great service if they were correctly trained to handle their work.

Not only can the consulting engineer help to pilot the engineering staff of an organization along the proper general lines, but he can often, through his experience, foresee trouble which if permitted to pass might ruin the reputation of a company. More than one concern has suffered materially in reputation for an error which allowed a weak link in its chain of construction.

We can call to mind a concern which was ranked among the biggest and most successful in this country not over four years ago. Three or four bad mistakes, one after another, any one of which would have been readily detected by an outside engineer of experience, were allowed to escape the vigilance of the plant engineer.

The result is that this company has lost all of its holdings and is only a mere shell of what it might have been had the proper care been concentrated on its product. One line of models had so much trouble with the rear axle that it was necessary to call in hundreds of these axles and replace them with new ones. It was necessary for the same concern to put scores of men on the road replacing pistons, which, because of faulty design, failed as soon as they got into service.

Following this a model which should have never been allowed to go further than the drafting board was put out with results that were disastrous and because of these mistakes the company shrank from an independent, wealthy concern until it now holds but a minor position in the industry. This is only one of the stories of what might be told of where the high ideal of quality performance was not kept in mind in designing the product, but rather where the cheapest thing that could be used was utilized to get by with on this car.

Should Design for Service

The fear of every manufacturer is what service problems he is going to run into after his product gets in the hands of users. One of the biggest reasons for this is that the problem is not fully considered *before* the product is designed, but only after it is ready to sell.

America is about to enter into a great contest for world trade. We have had a reputation, perhaps not undeserved, of building products cheaply but not enduringly.

The war has changed this to a great extent and countries which have hitherto kept closed doors for America's products are now ready to open them if we but step forward with the proper class of goods. This is an opportunity for which we might have had to wait a half century had not the war occurred, and it would be criminal folly to fail to take advantage of it or to destroy this wonderful opportunity by attempting to place before the markets of the world products which are not built on the ideas of quality and service.

The consulting engineer knows through his broad experience that it is possible to build a cheap product and sell it once because of its price, but it is not possible to secure repeat orders from the customers who have tried the cheap product and found that it does not give the service.

For this reason the consulting engineer is bound to be a weighty factor in demanding quality in the products with which he has anything to do. It is simply a matter of building a permanent re-order business, rather than a single-order, short-lived concern, which may flare up as a quick success, but which will not endure in anything like the manner of a concern whose product is built on a higher plane of standards.

There is some reason why in 1912 in this country there were something like 350 manufacturers of passenger automobiles, while in 1919 there are about eighty-five. Those who have survived have not been the ones who have tried to make an instantaneous financial success. Those who remain have always the temptation before them to cut down on quality and go up in annual profits.

But it is going to be the salvation of our industry and one of the greatest determining factors in the commercial standing of America in the world market if we will but make quality and not profit the chief consideration.

A consulting engineer who handles his work along these broad lines should be in the greatest demand. He can enter a conference with his broad view and bring out in discussion matters which probably would not occur to those who are connected with the plant organization.

It is not the consulting engineer's function to determine matters of policy or to entirely design a product unless under some special circumstance. It is his duty rather to see that in laying out a project all sides of the matter have been given due consideration and after this decision has been reached, he should assist in interpreting it in future production in the broadest and most accurate light.

A man who has made consulting engineering as pertaining to the automotive industry a study states that the consulting engineer's work can be considered under five headings:

1—Confirmation.
2—Criticisms.
3—Improvements and refinements.
4—Creation.
5—Checking and testing.

In considering these heads it can readily be seen that the matter of confirmation is of the highest importance because not only does the confirmation of the views of the factory men give them an infinitely greater confidence in their own judgment, but it makes a huge psychological difference to the entire plant, giving them greater ability to go ahead and push the project to a successful determination.

The statements of a consulting engineer in confirming from a broad viewpoint the detailed decision of a plant engineer are of the highest importance to the sales manager because they furnish him with the best kind of ammunition for his sales campaign.

Sales Problems Are Important

Often the sales manager will differ with the decisions made by the engineer of the plant. This condition is not healthy from a sales standpoint because it is a well-known principle of merchandising that before a man can sell well he must first be sold on his own product. The confirmation of a consulting engineer of high standing of a definite engineering policy decided upon by the plant engineers will have a wonderful effect in this direction.

Criticism by a consulting engineer must be taken in a broad way. The plant engineers must realize that constructive criticism by a consulting engineer is no reflection on their ability. Too often the petty fear of a plant engineer that his knowledge and effort will be discounted has precluded the use of a consulting engineer, when that use might have been worth thousands of dollars to the company.

A consulting engineer, knowing from his storehouse of engineering information the proper materials and proper design, or proper manufacturing methods to utilize in taking care of a product designed to fulfill certain requirements, can be a wonderful benefit to a plant.

Often important features can be improved and simplified by suggestion and by careful discussion. Manufacturing costs may be cut by a suggestion given as a result of the wide experience of the consulting engineer. The field of criticism is a fruitful one and has marvelous possibilities in the way of money saving and manufacture and trouble saving after the product is on the market.

As the art progresses refinements and improvements always suggest themselves in any product. From time to time factories have announced that they were ready to stand pat upon designs previously brought out and completed. In a sense they have said, "We have reached perfection and we know of no further refinements to incorporate in our product."

Tests of Ignition Apparatus

A New Porcelain Developed Having High Insulating Qualities at High Temperatures—Resistance to Thermo-Cracking and Shock and Gas-Tightness of Plugs Also Investigated

By P. M. Heldt

IN 1916 the Bureau of Standards was asked by the National Advisory Committee for Aeronautics to undertake a study of spark plugs, and this work was later extended to cover other ignition problems. Reports from abroad indicated that one serious trouble with spark plugs was failure of the plugs due to electrical conduction through the insulation. The ceramic laboratory of the Bureau, which is located at Pittsburgh, undertook to develop compositions of porcelain which should meet the requirements of spark plug insulators better than any available up to that time. A large number of compositions were made up and tested for electrical resistance at high temperature, for resistance to thermal cracking and for resistance to mechanical shock. In the test for resistance to change of temperature the porcelain was raised to a high temperature and then suddenly cooled by plunging it into an oil or other bath, after which it was examined for cracks or fissures. In these tests for resistance to mechanical shock the spark plug was screwed into the side of a block of metal which was struck violently against a steel anvil by means of a cam mechanism.

As a result of these tests a material was developed which was superior to any formerly in use. The formula of this composition has been furnished by the Bureau to a number of spark plug makers and may be had by any interested concern on application. The material is now in production by one of the largest manufacturers of spark plugs in the country, and its use is being considered by several others.

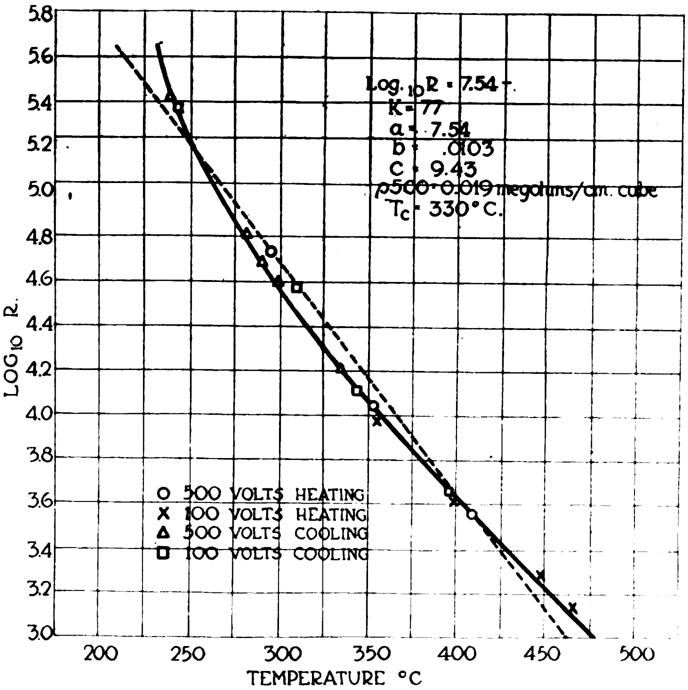
As a result of the conductivity measurements and of measurements of the temperature which the spark plug attains in an engine, it appears that failure of a plug due to conductivity of the insulator occurs only in extremely hot engines. The results of the conductivity measurements were plotted on cross-section paper, and one of the graphs is shown herewith. Instead of plotting the resistance of the porcelain against the temperature, which would seem to be the natural thing to do, the logarithm of the resistance is plotted against the temperature. The reason for this is that while the resistance varies enormously with slight changes in temperature, the logarithm of the resistance varies nearly linearly, and a nearly straight line is obtained, the inclination of which can be made anything desired by a suitable choice of horizontal and vertical scales. From this curve the resistance at any temperature can be read off.

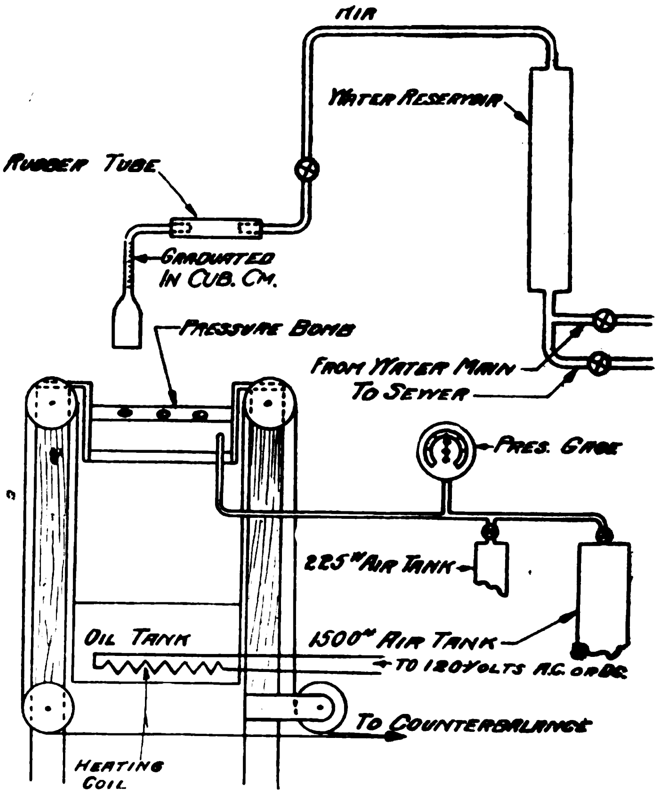
In the course of the experiments it was found that in high power aviation engines the inner end of the porcelain may reach a temperature of 900 deg. C., but the body of the porcelain seldom exceeds a temperature of 250 deg. C.

The following table gives the principal results of resistance tests on a variety of insulators used for spark plug purposes:

Description of insulator	T_e	Resistance at 500° C. in millions of ohms
Fused silica	890° C.	340
Best porcelain tested	790° C.	80
Typical high grade mica plug	720° C.	70
Average of three aviation porcelains	650° C.	40
Average of three automobile porcelains	490° C.	0.80

T_e is the temperature at which a centimeter cube of the material has a resistance of 1,000,000 ohms.





Logarithmic graph showing variation of insulator resistance with temperature. On right—Apparatus for testing air-tightness of spark plugs

Tests have also been made on the gas tightness of plugs, more than 100 different designs having been tested. Except in cases where the insulator is molded to the metal parts of the plug there is very little connection between the design and gas tightness, the latter depending much more on workmanship than on design.

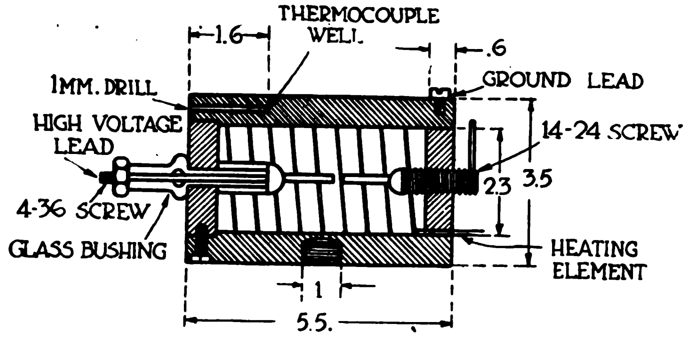
There are several different methods of insuring a gas-tight joint between the metal shell and the insulator. A great many plugs are assembled with a screw bushing, in which a gasket, either of asbestos thread or copper asbestos, is placed between a shoulder on the shell and a shoulder on the insulator. Other plugs have the edge of the shell crimped over the insulator, while still others depend upon a taper fit, these latter not employing a gasket.

In making a test for air tightness the spark plug is screwed into a pressure bomb, and a bath of oil heated to 150 deg. C. is brought up around the plug and produces a differential expansion similar to what would occur if the plug was in an engine in operation. Then a graduated glass bell is placed over the plug and any air which leaks through is collected therein. The volume of air which collects in a given time is a measure of the air-tightness of the plug. A sketch of the test set-up is shown here, and one of the illustrations shows a few of the plugs submitted for test, practically all of which will be seen to be of the airplane type.

This section of the Bureau of Standards has also made numerous oscillograph tests of magnetos and battery ignition systems for the War Department. Among other testing apparatus the Bureau developed a copper calorimeter for measuring the heat of the spark. A sectional view of this device is shown herewith. The spark takes place inside of a cylindrical block of copper, 2 in. long by 1 in. in diameter, which contains one insulated and one grounded electrode, the spark gap being at the center of the block. The temperature difference between the calorimeter block and another dummy block of similar dimensions is determined by means of a thermocouple, and the whole apparatus is calibrated by means of a resistance coil inside the cylinder through which a certain known amount of electrical energy is sent.

The actual igniting power of a spark depends on many factors which are at present little understood, and the total heat energy is by no means a direct measure of this igniting power. However, it serves to give an index of the total power output of each type of ignition system and forms a basis for a study of the effect of various features of design upon this output.

In arranging the set-up for this test, pains were taken to reproduce as nearly as possible the electrical conditions in an engine while in operation. The spark is produced under atmospheric pressure only, but the spark points are separated further than in the spark plug, to such an extent that the breakdown voltage and the voltage required to maintain the pression.
arc are substantially the same as in an engine under com-



Calorimeter for determining heat of sparks

Measurements were also made of the breakdown voltage of spark gaps at various pressures and temperatures in order to estimate the voltage required to produce a spark in the compressed charge in an engine cylinder. It was found that the spark voltage depends only on the density of the gas, the pressure and temperature of the gas affecting the breakdown voltage only in so far as they have an influence on the density of the gas. These data agree with actual measurements in aviation engines and indicate that the sparking voltage is approximately 6000 volts.

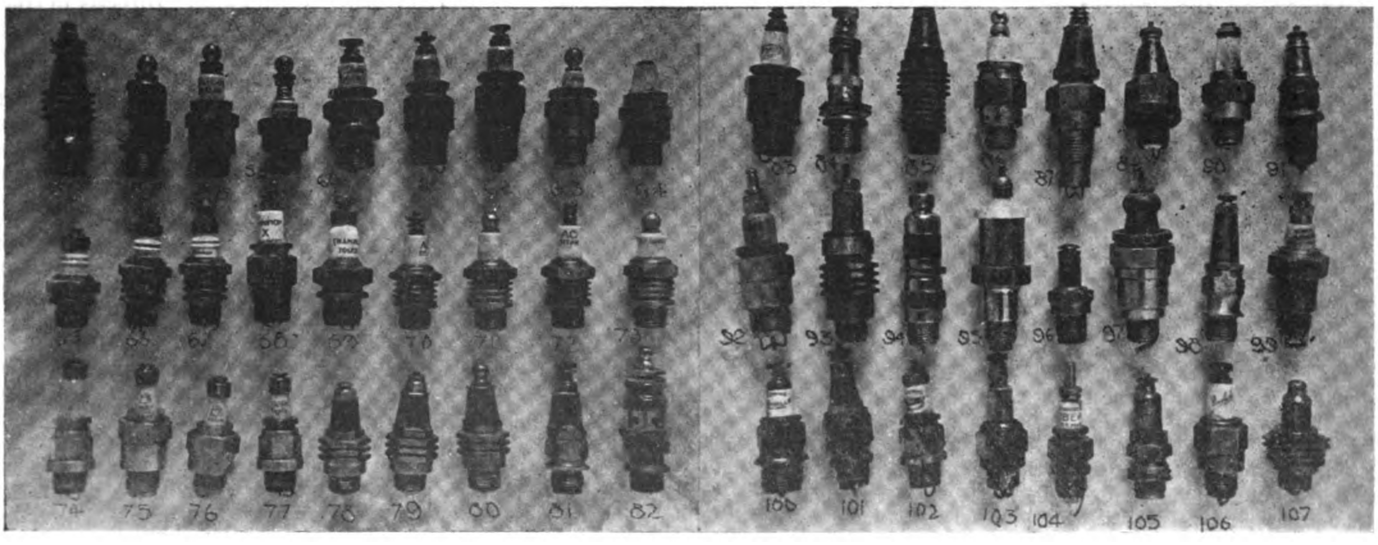
—

Investigation of Headlamp Glare

ABOUT a year and a half ago the Bureau of Standards started an investigation to determine the character of light distribution of automobile headlamps with various kinds of glare-control devices. Candlepower measurements were made on 20 to 25 different types.

These glare-control devices were divided into two different types, one in which the light distribution is symmetrical around the axis of the reflector and the other in which it is not. With the former type candlepower measurements were taken only in a horizontal plane through the axis of the lamp, through a range of about 10 deg. from the axis. Where the beam of light is not symmetrical to the axis of the lamp, as, for example, with lenses containing prisms which throw the light downward, measurements were made in four horizontal planes 2 ft. apart at a distance of 75 ft. from the lamp.

What started the Bureau on this work was a request from one manufacturer of headlight lenses for a test of his device. Later the work was conducted in collaboration with the Automobile Headlight Specifications Committee of the Illuminating Engineering Society. E. C. Crittenden of the Bureau of Standards is a member of this committee, and he was represented in most of the tests held by the Committee in New York by A. H. Taylor.



Some of the spark plugs tested by the Bureau of Standards

Motor Cultivators at Kansas City

Corn and Cotton Cultivation Problem Solved Along Two Different Lines—Light, High-Clearance Tractors for Use with Horse-Drawn Type Cultivators and Special Machines Fitted with Motor Drive

By P. M. Heldt

KANSAS CITY, MO., March 9—During the past year considerable attention has been given by implement and tractor manufacturers to the problem of a motor propelled or motor-drawn cultivator. It is generally realized that before the farmer can dispense with his horses he must be offered machines for doing all the different kinds of work for which he now uses horses. The ordinary tractor is unsuited for cultivating, as it is much too heavy, has too much power and not enough clearance. There are two possible directions in which a solution can be attempted, namely, by building specially light tractors with high clearance, to which cultivators similar to the horse-drawn implements can be hitched, or by building a cultivator to which an engine, transmission, final drive and steering gear can be applied.

Among the requirements made of motor cultivators is that they should have a considerable range of speed. This is necessary because when cultivating the corn the first time, when the plants are still very small, the machine must be driven at low speed, in order that none of the plants may be covered up with earth. A speed of about 1 m.p.h. is generally considered suitable for this operation. Motor cultivation requires only a moderate amount of power, and there is no doubt that by building a special cultivator to which an engine, transmission and final drive are attached the highest degree of operating economy can be secured.

Practically all the cultivators so far built are of the two-row type. The latter are always fitted with three wheels, two driving wheels of about 40-in. diameter and an additional central wheel, which may be either at the front or at the rear. This last-mentioned wheel of course runs midway between the two rows that are being cultivated. In using a machine of this type care is always taken to cultivate at the same time two rows which have been planted together, as the spacing of these rows is absolutely accurate. The cultivator gangs are guided by means of the feet, and all the operator has to do is to watch one row, as with the rows of corn uniformly spaced and the gangs of the cultivator set exactly the right distance apart, if the gangs are properly guided for one row they will also be guided properly for the other row.

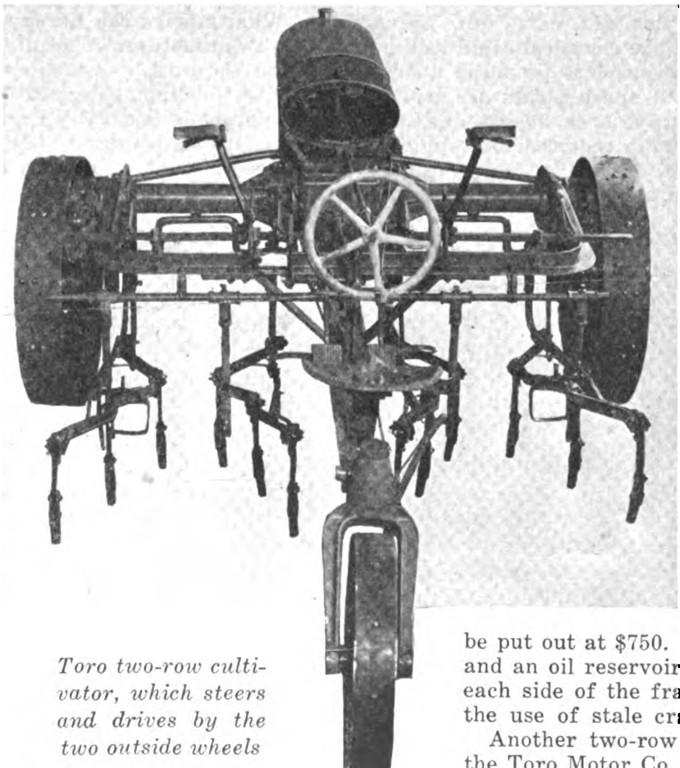
One of the first motor-propelled cultivators in the field was the Avery, manufactured by the Avery Co., Peoria, Ill. This is a 3-wheeled construction, with a single central steering wheel in front and two driving wheels at the rear. A structural-steel frame carries the engine, transmission and differential shaft, from which latter the drive is by bull gears to the driving wheels. The power plant is the same as that used on the 5-10 horsepower Avery tractor, comprising a four-cylinder block engine of 3 in. bore and 4 in. stroke, and a three-speed sliding gear transmission, giving a speed range of 1 to 3 m.p.h.

The machine is 84 in. wide over the driving wheels. The steering mechanism for the front wheel is controlled by means of a handwheel through a shaft extending along the top of the engine bonnet. It consists of a pair of bevel and a pair of spur gears. In addition to steering by the single front wheel, provisions are made for using the driving wheels for steering. A brake of the band type is located on each of the differential shafts, each brake being operated by means of a separate lever, and by applying the brake to one shaft (thus locking one of the driving wheels) and applying power to the other driving wheel, the cultivator can be made to turn around one of its driving wheels as a pivot.

Gasoline Recommended as Fuel

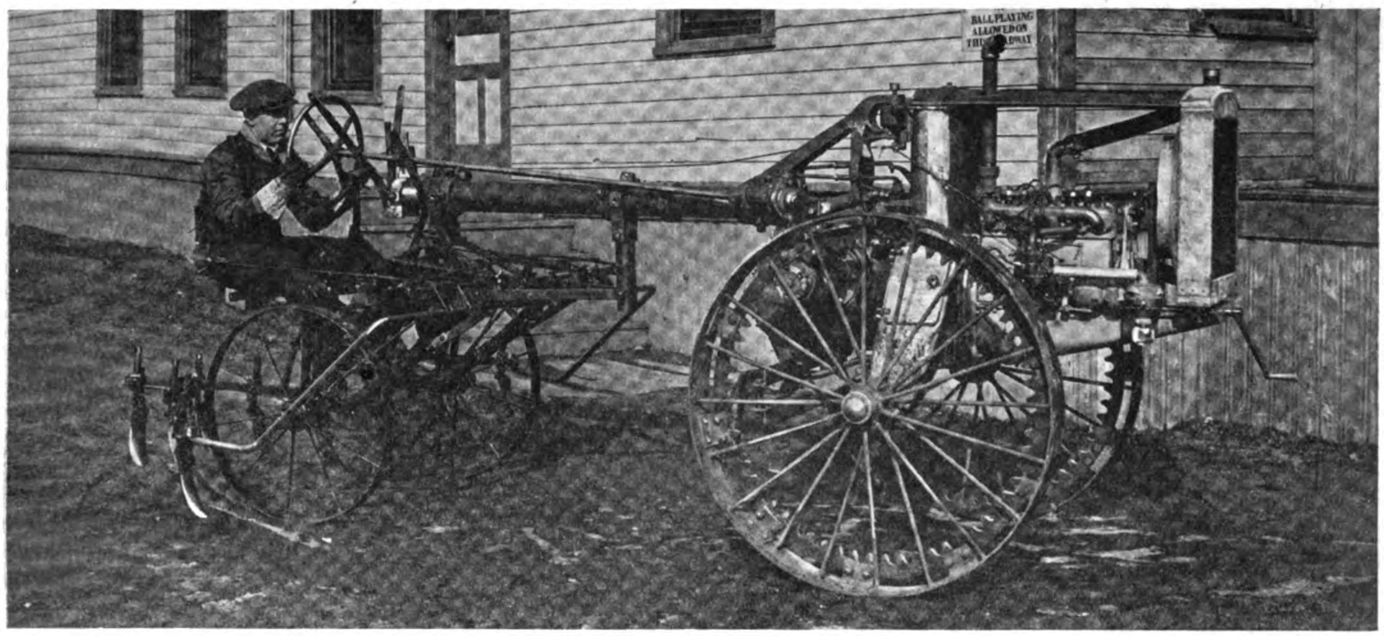
Gasoline is the fuel recommended, and a supply of 9 gal. can be carried in the tank on the engine. The driving wheels measure 42 by 6 in. and the steering wheel measures 28 by 5 in. The width between the center of drive wheels is 93 in., when built for 40-44 in. rows, but the machine is also furnished for special widths of rows. The clearance under the frame is 30 in.

This machine weighs 2800 lb. and is capable of taking care of 100 acres of crops in a season, which is said to be about twice as much as can be attended to with one team of horses. There is a seat for the operator on the bar extending back from the frame, the operator's feet resting on the lever for controlling the lateral motion of the cultivator gang. Directly in front of the operator are levers for applying the brakes to one or the other side of the differential, for changing gear, withdrawing the clutch and for lifting the cultivator gangs. With this cultivator the Avery company furnishes as extras a weeder attachment, a lister attachment, a check row attachment and a belt attachment. The price is $650 for the four-cylinder machine as described. A six-cylinder machine of the same cylinder dimensions will also be put out at $750. The bull gear drive is exposed, and an oil reservoir for lubricating it is located on each side of the frame. The company recommends the use of stale crankcase oil in these oilers.



Toro two-row cultivator, which steers and drives by the two outside wheels

Another two-row cultivator is manufactured by the Toro Motor Co., Minneapolis. This is equipped with a four-cylinder 3⅛ by 4½ in. engine, a dry-



Double-row cultivator attached to new Allis-Chalmers light tractor

disk clutch and a two-speed transmission of the heavy duty type. The cultivator is of three-wheel construction, the third wheel being located centrally at the rear. Steering is effected either by turning the driving wheel around the pivot support or applying a brake to one or the other of the differential shafts. The engine is fitted with a governor, and the gearing is such as to give theoretical speeds of 2 or 3 m.p.h., but owing to ground slippage the actual speeds are 1¾ and 2¾ m.p.h.

This machine has an overall width of 80 in. The cultivator gangs are controlled by one lever for each set, and there is also a lateral control by means of a pedal. Drive axle housings of 5 in. piping are secured to each side of the transmission housing, and to the ends of these 5 in. pipes are secured the steering heads. To the differential shaft housings is also secured an angle iron frame to which the different control members are attached. The front wheels measure 36 by 7 in. and the rear wheel measures 24 by 4 in. The drive to the front wheels is by means of an internal gear almost the full diameter of the drive wheel. A universal joint is inserted in each driving shaft, the center of which is in line with the steering pivot axis. While gasoline is to be used as the fuel at the start, it is the intention later to furnish kerosene burning equipment. The clearance is about 36 in.

Bailor's Two Types

Both a single row and a two row cultivator are exhibited by the Bailor Plow Mfg. Co., Atchison, Kan. The single-row cultivator is intended specially for cotton cultivation in the South. This is a four-wheel construction, the front wheels being mounted on a yoked axle to obtain the necessary clearance at the center of the machine. The cultivator is steered by swinging the front axle around its center support.

This machine is equipped with an 8 hp. Cushman two-cylinder, two-stroke engine, Kingston carbureter, Dixie magneto, air cleaner, Borg & Beck 10-in. clutch, a sliding gear transmission affording two forward and one reverse speeds, and chain drive to the rear wheels. The machine has an angle iron frame to which are secured the cranked rear axle and a bracket to which the cultivator gangs are attached. The cultivator is very much the same as made by Bailor for horse work. It can be equipped with either two or three shovel gangs. The weight of the machine is 1100 lb.

The two-row Bailor cultivator is fitted with a four-cylinder Leroi engine, Holley or Kingston carbureter, Borg & Beck 10-in. clutch, Dixie magneto, sliding gear transmission and chain drive from the differential shaft to a counter shaft and thence to the rear driving wheels. This machine is of the three-wheel type, having a single front wheel mounted in a caster yoke. Steering can be effected either by turning the single front wheel or by applying a brake to one or the other of the jackshafts. The frame is adjustable for different widths of rows. This machine weighs about 2000 lb. While each set of cultivator gangs can be lifted by a single lever there are two small levers adjacent to each of the aforementioned levers for controlling the relative height of each shoe.

Moline Universal

Among the lighter tractors designed to handle cultivators in addition to plows and other implements is the Moline Universal. The Moline Plow Co. manufactures a special two-row cultivator, which can be hitched to the draw-bar of this tractor. The seat is on the cultivator and the steering wheel, engine control handles, clutch and gear levers are within easy reach of the operator. A special feature of the Moline construction is that the operator does not sit in line with the center of the tractor but to one side in line with the right hand bull wheel. This gives him a clear view of the row directly ahead. This off-set hitch feature, as it is called, enables the driver to steer the tractor very closely, the design being such that the inside wheel of the tractor must be kept a certain distance from the outside row. For dodging individual hills the cultivator gangs are shifted by the operator's feet. Use is made of a so-called pendulum gang shift. The gangs are suspended at three points and are shifted by pedals. When the foot pressure is released the gangs automatically return to the center. When the corn is accurately planted and the tractor is driven straight, only very little shifting is required. Only one lever is used for raising the gangs, which are automatically leveled when raised regardless of their individual adjustment for depth. This adjustment for depth is made by a double acting hand screw. Strong springs are provided to assist in raising the gangs. The gangs are held to their work by pressure rods with compression springs. The gangs may be adjusted laterally for cultivating rows of from 40 to 46 in. The wheels of the cultivator are 40 in. in diameter with 4 in. concave tires and have dust-proof hubs and large hard oil compression grease cups.

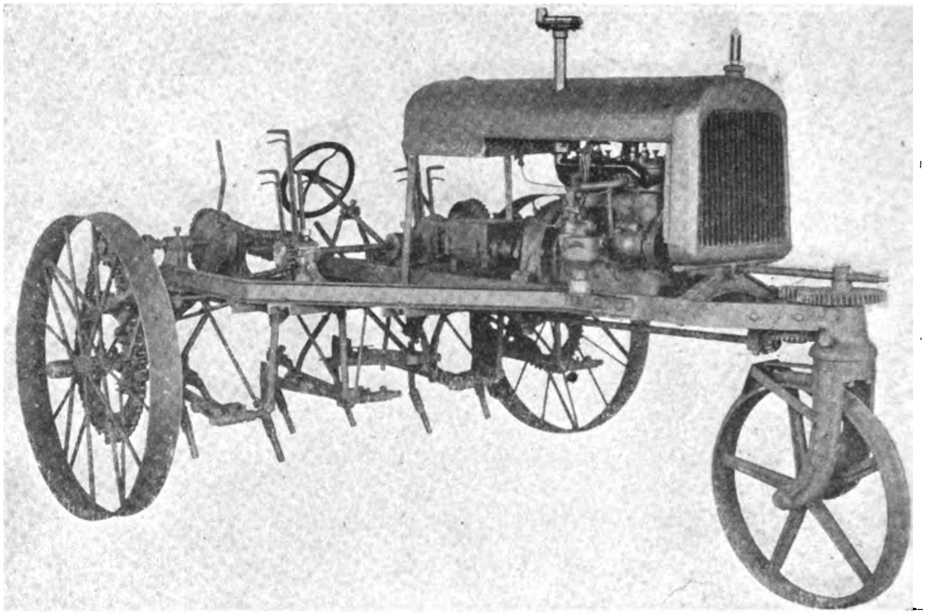
The Moline tractor weighs 3360 lb. and the cultivator 924 lb. The electric governor of the Moline, by means of which the engine speed can be varied within wide limits, is a specially valuable feature in corn cultivating. The governor adjustment is located immediately in front of the driver, and the operating speed can be instantly varied. For the first cultivation a speed of ½ to 1 m.p.h. is recommended; for the second, 2 to 2½ m.p.h., and for the third, 3 m.p.h.

The light tractor recently brought out by the Allis-Chalmers Co., Milwaukee, is also adapted for cultivator work. This

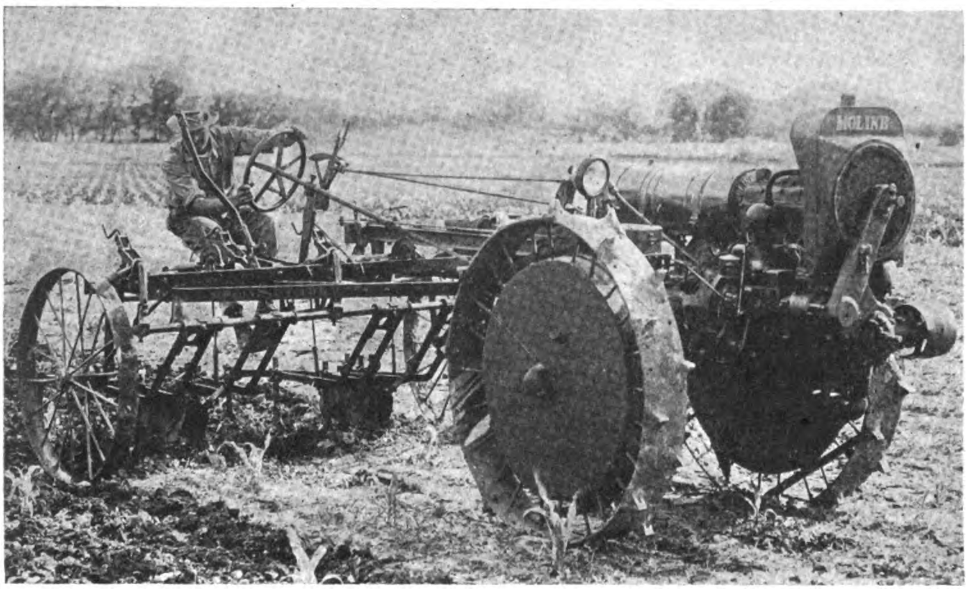
machine is rated at 6 hp. on the drawbar and weighs 1850 lb. It has a ground clearance of 28 in. and can be turned in a 16 in. circle.

Indiana Tractor

Another small two-wheeled tractor adapted for cultivator work is marketed by the Indiana Silo Co. of Anderson, Ind. It weighs 1700 lb. and is claimed to be capable of cultivating 20 acres a day with a two-row cultivator. The hitch of this tractor is so designed that almost any implement can be attached by means of two bolts which make a rigid hitch. Thus the tractor and the implement become a single unit, allowing the operator to control both, the same as he does with horses. This tractor is equipped with a four-cylinder engine of 3⅛-in. bore and 4½-in. stroke. Four different speeds may be obtained by changing driving sprockets. The final drive is by chains and steering is by rack and pinion. The usual change gear is omitted, and no change of speed, or, rather, of gear ratio, can be made from the seat. This, of course, helps to reduce the weight of the tractor.



Bailor two-row cultivator, steering both by the single front wheel and by the two rear wheels



The Moline is the only one of the larger tractors having sufficient clearance to permit of its use for cultivating

No Special Implement Needed

While it is recommended by the manufacturers of this tractor that the farmer should purchase a plow specially designed for it, most of the other stiff-tongued farm implements are available for use with the tractor. The clearance is the same as that of the standard corn cultivator and the claim is made by the manufacturers that less corn will be knocked down than with horses. Another point made is that frequent cultivation increases the growth and yield of corn and, as the tractor does the work in shorter time and therefore permits of this, it should lead to increased crops.

Dry Cell and Storage Battery Work of the Bureau of Standards

G. W. VINAL of the Bureau of Standards has been engaged in some work on dry cells and also has drawn up specifications for storage batteries for industrial trucks and tractors, the latter for the use of the Army. As a result of the work, a bulletin will shortly be issued by the Bureau of Standards which will contain a general discussion of the working principles of dry cells, enumerate the different types in use, give a list of standard sizes in which the cells are made and propose standard methods of tests. There are two ranges of sizes of dry cells, the small ones being used almost exclusively for pocket flashlights. Of the three larger sizes, the intermediate one, the 2½ by 6 in., is much used for ignition work. The two other large sizes are 1½ by 4 and 3½ by 8 in.

The forthcoming circular, No. 79, on dry cells will contain specifications for tests, including a continuous discharge test through a fixed resistance and an intermittent discharge test. It is of interest to know that although the use of dry cells for automobile ignition has been almost entirely abandoned, still 71,000,000 dry cells of the larger sizes were manufactured in 1914, and the production is said to have increased considerably since that time. The recent large increase in the price of dry cells is chiefly due to the scarcity of black oxide of manganese which is used as a depolarizer. Previous to the war this material was obtained from Russia, which source of supply has now been entirely cut off. At the present time we obtain our supplies of this chemical from South America, Japan and Cuba, and some is also mined in the United States.

The storage battery work done by this section has been entirely for departments of the Government and has been of a confidential nature, so that no results can be given out. This work has been in progress for more than a year. In 1914 the weight of storage battery plates produced in this country was 41,000,000 lb.

Tractor Problems That Are Awaiting Solution

Kansas City Show Suggests Need for Lighter Weights—Improvements in Transmissions—Better Dust Preventives—Parts Makers Are Important Factor

By David Beecroft

KANSAS CITY, MO., March 10—No greater deduction could be carried away from the tractor show here than that those national parts makers who have been such cornerstones in the automobile and truck industries are rapidly taking similar positions in the tractor industry and that the history of the tractor industry will be inseparably connected with them.

It was these makers in tens, fifties and hundreds at the show that gave it such an international significance. The products of these makers are known in the four corners of the world and no matter what kind of products they are they will help to merchandise such a product. There is great value in a reliable, well-known part in any vehicle.

So often is the story of improvements in a tractor largely the story of what these stalwarts in the manufacturing world have done in the past year. You ask in what way a tractor has been improved and the maker points with pride to an improved engine that has been purchased outside; or to anti-friction bearings in the wheels; or to an improved magneto with impulse starter; or to better and lighter wheels which have come from the parts maker; or he draws your attention to an improved radiator, an improved governor, an improved frame or an improved axle.

Parts Makers' Names Help Sales

The use of many of these parts which have been more or less standardized for international sale will make the export trade of tractors easier than it would otherwise be. If our tractors are fitted with anti-friction bearings which are interchangeable with French, British, Italian and German bearings then the maintenance of these tractors in foreign fields is correspondingly easier. It is going to be easier to sell a tractor in Australia that is so fitted. The same is true with regard to practically every other country. Such a design makes it easier for the dealer. He can secure stocks more easily. He has not so much money tied up in stocks of spares. He has a more fluid maintenance system.

Tractors must be furnished for nearly every nation. The American tractor maker has had a good export trade for several years. It dates from the huge traction engine types that got us into trouble in several countries because of the lack of competent repairmen to keep them operating. The maker must have foreign trade in view when designing his tractor.

It is putting the cart before the horse in export trade to design a tractor for home conditions and after it is completed think of selling it in the export field as well. Ninety per cent of the tractor may be suitable for foreign trade, but there may be some little parts that are going to be trouble makers. Have the foreign trade thought constantly in mind. The world will need tractors and if we do not do our part in furnishing them then we are leaving the field to some one else and in short asking those people to build up huge organizations while we let the markets slip through our fingers. We have some ships and we are going to have more and we must produce products for them to carry to all lands in order that we can be assured of getting from those lands what we need in raw materials for our industries and national life.

Foreign countries are taking up questions of tractor design in earnest. They will have their tractors for sale in the world's markets. They may set a standard of excellence that we will have to reach up to. They may establish the fact that the cheapest tractor is not always the lowest-priced one. The foreign maker's standards must be heeded.

The aim for lighter parts has taken hold in many factories. It has been demonstrated for 3 years that weight is not a first essential to tractive effort. Tractors have been in existence for some time in which the drawbar pull is in excess of the weight of the machine. With this a demonstrated fact it scarcely seems necessary to have tractors in which the weight is more than twice the drawbar pull. In such engine power is being used to transport a weight that could be eliminated.

Further chapters in weight reduction will be written when the use of stampings becomes more general. Some of the big pressed steel firms have not yet started making tractor stampings.

The use of stampings in creeper types has not even begun. It has been under consideration. There is a need for it and yet the work has been delayed. The heavy weight of the creeper tread is generally commented upon. Some makers admit a 50 per cent increase in weight of a creeper as compared with a wheeled type and yet the final step in creeper progress has not been started.

Problem of Power Application Difficult

The complete problem of engine power in relation to work to be done is not yet solved by all. Sometimes the power of the engine is not efficiently transmitted to the wheels. There are cases where the wheel diameter has not been carefully calculated with regard to engine power. Wheels are in some cases too large and in others too small in diameter. More engineering is needed.

There is yet a lack of uniformity and there may not be much uniformity for some years in power transmission. The problem is so much greater than in the automobile or truck due to greater gear reductions that there are bound to be differences of solution.

One maker uses the worm as a final reduction, whereas another uses the worm in his intermediate reductions where he can have a high worm speed. The same maker uses spur reductions in the final stages where speeds are low. The best place for the worm is a subject of discussion.

The use of very large transmission gears common a few years ago is fast disappearing. The cast gear of large diameter and great weight is being replaced by gears that are little larger than those used in trucks. There is much yet to be done. The making of gears must be carried to greater lengths in tractors than in cars and trucks. The development of a stout tooth for heavy tractor service has to be carried on. A few makers have for a three-plow tractor a gearset very little larger than in motor trucks. These gearsets are remarkable in comparison with the huge gears of other makers.

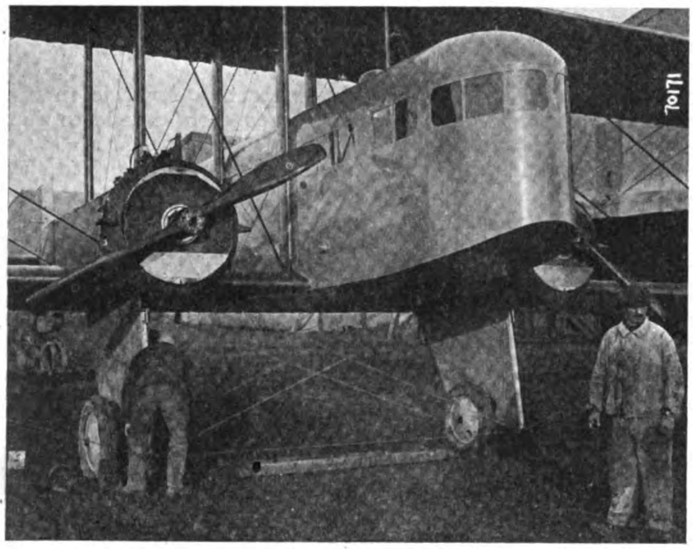
In some gearsets too many gear reductions or stepdowns are used. There are cases of five different stepdowns. This means too great a multiplication of gears. It means too heavy a gearbox. It means added bearing cost. What some do in five stepdowns others are doing in three and some in

(*Continued on page* 601)

Ambitious Flights Planned Abroad

Caudron and Farman Rivals in London-Paris Flights—Vedrines Planning World-Round Flight —Farman Bomber for Daily London Route

By W. F. Bradley
AUTOMOTIVE INDUSTRIES' *European Correspondent*



Closed cabin and one of the Salmson 9-cylinder star engines used on Farman passenger-carrying airplane

PARIS, Feb. 15—Two French firms, Caudron and Farman, are anxious to establish a regular aerial service between Paris and London. The machines are ready and have undergone their trial flights very satisfactorily, but neither can leave owing to the refusal of the British Government to give permits for civilian passengers to be carried; in consequence, the Farman machine will probably leave in a few days with a military pilot and military passengers. This, however, does not satisfy Henri Farman, whose desire is to establish a regular aerial route between Paris and London.

The Farman machine was originally designed as a big bomber; it has a wing spread of 92 ft. and a total area of 1775 sq. ft. It is equipped with two Salmson Star engines having a total power of 540 hp.; it carries a useful load of 6600 lb. and has a total weight of 11,000 lb.

Its horizontal speed is practically 100 m.p.h. and its landing speed only 37 m.p.h. It will climb to 1600 ft. in 4 min., 3200 ft. in 10 min. 30 sec., 5000 ft. in 17 min., and 6500 ft. in 25 min. The gasoline and oil consumption of the two engines is 104 lb. per hour. As the distance of 200 miles which separates Paris from London can be covered in practically two hours, the weight of fuel and oil consumption on the trip will be about 210 lb. for each journey.

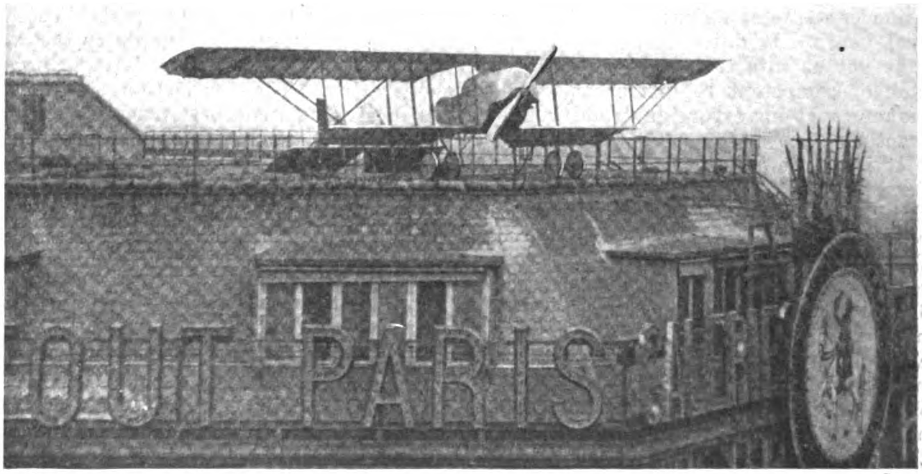
Making allowance for the weight of wireless apparatus and other internal fittings, the machine has a capacity for 30 passengers. Farman has fixed the cost of the round trip by air at $80. It is intended to make the journey from Paris to London via Lille and Boulogne-sur-Mer. A stop would be made at these two intermediate towns whenever necessary, but, of course, no stop will be made when passengers have been booked right through.

The second machine which is waiting to start the Paris-London service is a Caudron biplane type 23. This machine has a useful load capacity of 2600 lb.; thus it will carry 12 passengers on its trip from Paris to London.

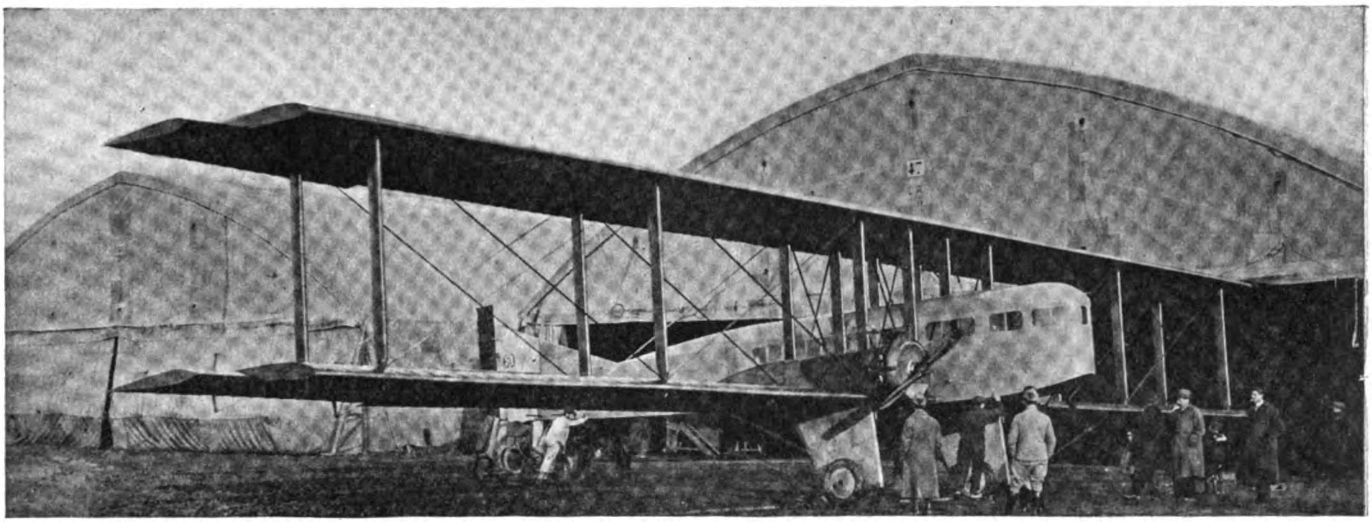
Verdrines' Exploit Nets Him $15,000

The machine with which Jules Vedrines landed on the roof of the La Fayette dry goods store last Sunday is a Caudron biplane type G3, equipped with a Gnome rotary engine. The available landing space was only 66 ft. long by 23 ft. wide. A considerable time before the war the owners of this building offered a prize of $5,000 to any aviator who would land on the roof and get away again. This offer was looked upon as a little cheap publicity, for it was never imagined that any attempt would be made to win the prize. For several days before making the attempt Vedrines had practised landing within a circle having a radius of 65 ft., and had been able to accomplish this successfully every time. The machine, which is a tractor type, is exceedingly flexible, planes well, and lands easily; it has been made use of during the war for training air pilots. Vedrines made his successful landing on this roof on Sunday morning, in the presence of very few people. By this exploit he has gained $15,000, for in addition to the $5,000 offered he had taken bets to three times this amount.

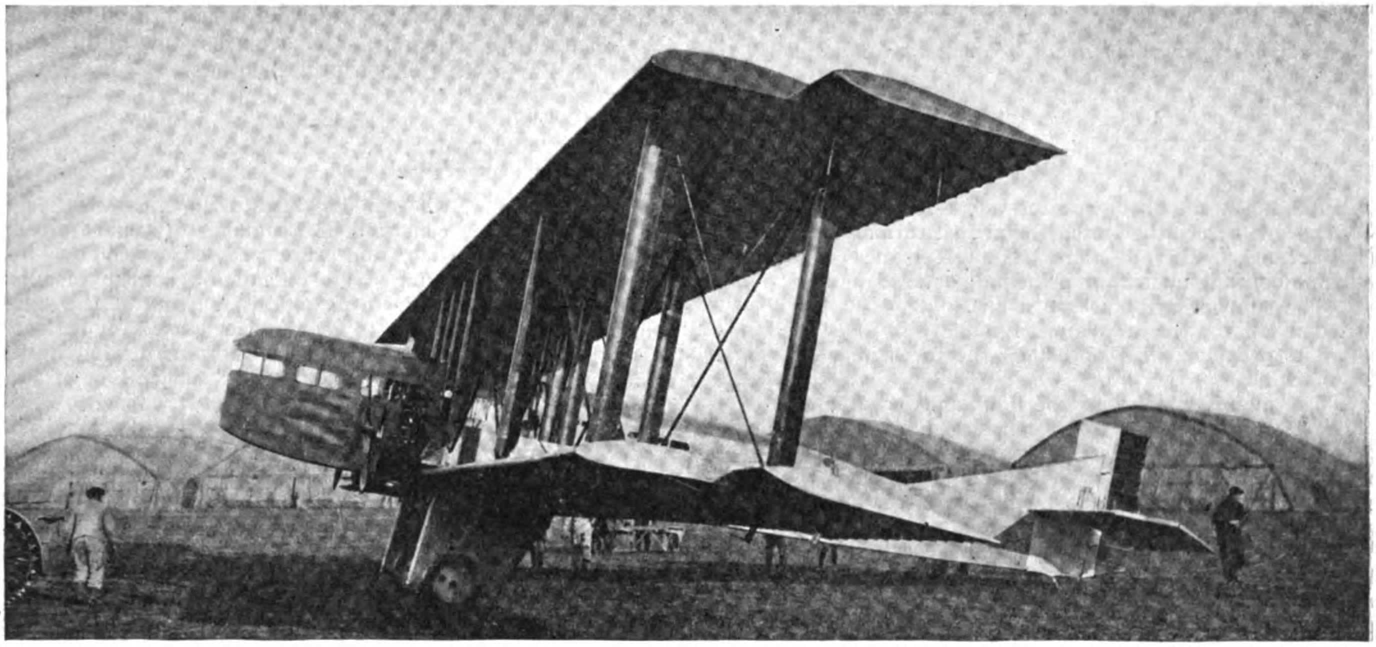
During the war Vedrines has been employed almost



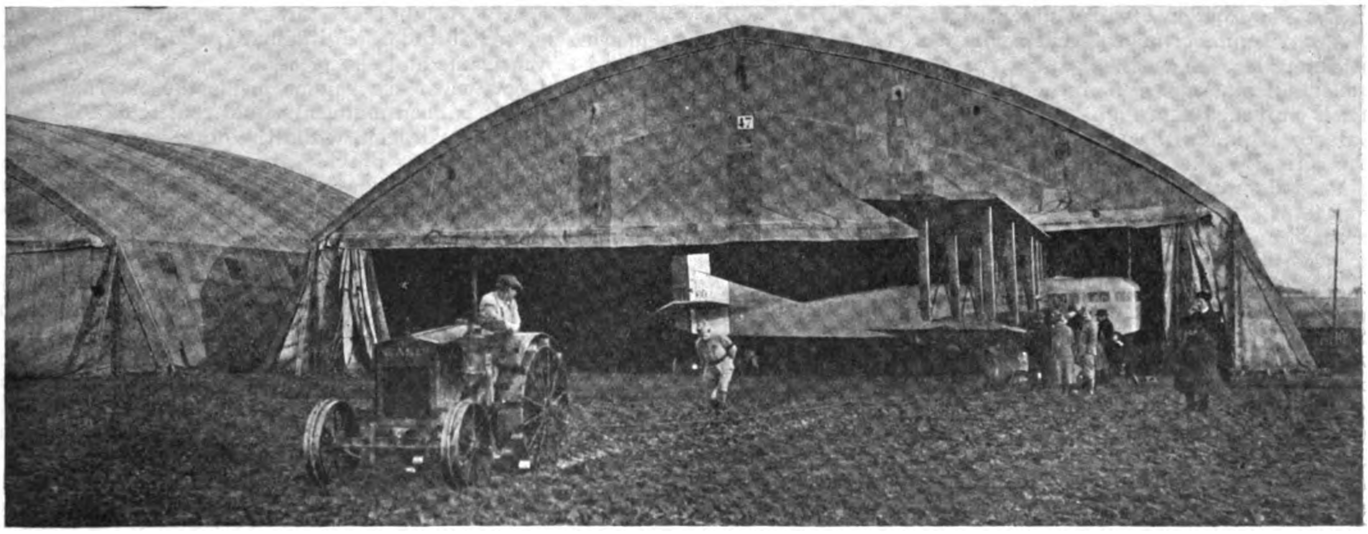
Vedrines' biplane on the roof of the La Fayette dry goods store



Farman biplane built to undertake regular passenger service between Paris and London



Big Farman biplane which will undertake a regular service between Paris and London with 20 passengers aboard



Farman biplane being hauled out of its shed by a Case agricultural tractor

First passenger going aboard Farman's Goliath, built for Paris-London service

exclusively on the difficult task of landing secret service agents in Belgium and on German territory, then calling for these men some days later at an appointed place. During his civilian and military career, Vedrines estimates that he had flown 310,000 miles. It is the intention of Vedrines, at an early date, to make a non-stop flight from Paris to Rome and return in 24 hr. For this trip he would make use of Caudron biplane type C-23, a start being made from Paris at night time under a full moon.

Will Fly Around World

Later, Vedrines declares that he will make a flight around the world. Starting from Paris, he would fly over Spain, into Africa and Madagascar; from there he would proceed to Asia by way of Persia, British India, and then to Siam, China, and Japan. He states that he will fly to America via Behring Straits. He would fly right down the Pacific coast line from North America to South America; he will visit Brazil, Guiana, Venezuela; then to St. Louis, Washington and New York; from the United States he intends to fly into Canada and Newfoundland, and from there he would make a trip across the Atlantic to Ireland. He declares that he would return to Paris via London and Brussels.

Development of Air Traffic

A PAPER on the above subject was read recently by A. P. Kapteyn before the Dutch Royal Institution of Engineers. The author points out that the performance of a flying machine depends upon four principal factors:

1. The supporting planes or wings.
2. The car for the crew and engine.
3. The propeller which produces the forward movement of the machine.
4. The motor, which must be light and powerful.

The two chief points to be considered in connection with the design of the wings are lifting power and resistance to passage through the air. The former determines the carrying capacity of the machine, while the latter has an important bearing on the motive power required.

A large number of experiments have been carried out by Mr. Eiffel and other investigators, in which models of wings were placed in a large tube through which air is propelled at a high velocity.

The lecturer is of opinion that the soaring of birds, which apparently takes place without any expenditure of force, depends on some natural phenomenon at present unknown, which, if discovered, would lead to important developments in the construction of airplanes.

A large number of experiments have also been carried out to determine the most advantageous shape of car and propeller. A stationary car model is placed in a tube by which air is propelled at a high velocity, while a special measuring balance registers the resistance they offer to the passage of the air.

Propellers driven by electric motors are similarly tested in quiescent air. These experiments are carried out under ordinary atmospheric pressures as well as in rarefied air, so as to ascertain the decreased resistance in the upper layers of the atmosphere.

The Dutch Government has decided to build a similar laboratory in Amsterdam so that the Dutch manufacturers may have all the necessary information on this important subject at first hand.

The lecturer describes the ordinary maneuvers possible with spherical balloons, the decrease in lifting power in the upper layers of the atmosphere and the usual means for regulating the altitude of flight, such as allowing gas to escape, throwing out ballast or pumping air into the balloon. He next describes the dirigible airship, and shows that the first airships made by Giffard, Hänlein and others were only about 165 ft. long, whereas the latest Zeppelins were over 400 ft. long. They consisted of a number of separate cells in an aluminum frame, and were provided with 1500-hp. engines capable of flying 55 to 62 miles per hour in quiet weather, but were unable to fly against a wind of the same velocity. It is not possible to get the fabric used for balloons quite hydrogen gas-tight, as even the best material permits 0.039 to 0.056 cu. ft. of gas to escape per square foot of surface per 24 hr. A Zeppelin of 1,800,000 cu. ft. capacity would therefore lose some 27,000 cu. ft. of gas per 24 hr. The escaped hydrogen gas is retained in the outer envelope, where it mixes with air and forms an explosive gas that has caused a number of accidents. This, together with the great weight of the aluminum framework, limits their sphere of action. If the danger of explosions could be eliminated and the weight of the frame reduced, a really useful airship might be built.

Mr. Boerner proposes to build dirigible airships of great size and recommends a length of 700 to 1000 ft., the frame to consist of three deep aluminum girders with short pointed pieces. The cabins, motors and propellers would be suspended between the girders. The cells containing hydrogen would be nearly rectangular, three being jointed together transversely, and 20 to 30 longitudinally, and all to be firmly secured to the frame and end pieces.

One-third portion of the volume inside the external cover which is to be of balloon material would consist of cells completely filled with hydrogen, while the other spaces could be partly filled in order to provide expansion for the external pressure varying according to altitude. To prevent explosions, the space between the cells and the outer cover is filled with hydrogen.

The ship would be driven by thirty-four 200-hp. motors arranged in two rows, each motor to drive its own propeller, adjustable for driving in any required direction, viz., upward, downward, forward or backward. The ship can thus be completely controlled by the engines. It is proposed to balance the ship automatically both longitudinally and transversely by pumping gas from one end to the other.

The author suggests that the airship should, on arrival at its destination, "land" in water and that passengers should step out on a pier as from a steamer. Re-starting from the water should be effected by the motors for vertical movement. He does not anticipate any difficulties either in building or maneuvering such an airship.

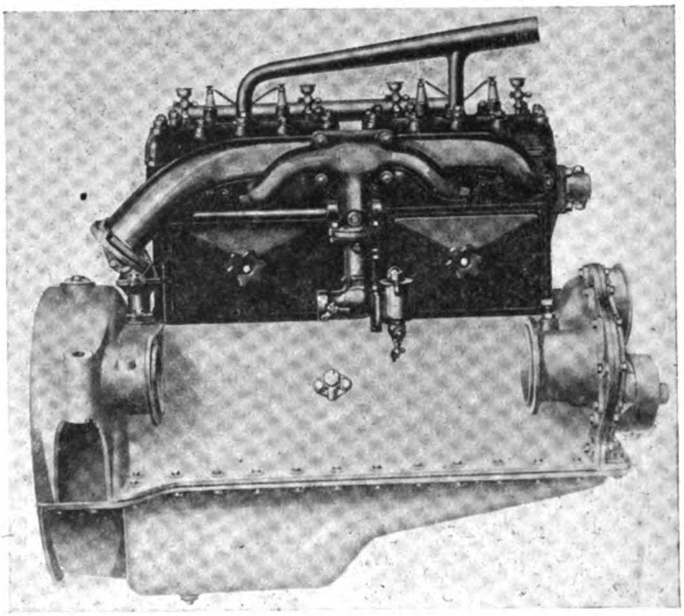
Three Hinkley Engines Built Around Class "B" Design

Models Suitable for 4 to 6-Ton. 3 to 4-Ton, 1½ to 2½-Ton Trucks and Tractors Drawing 1 to 4 Plows

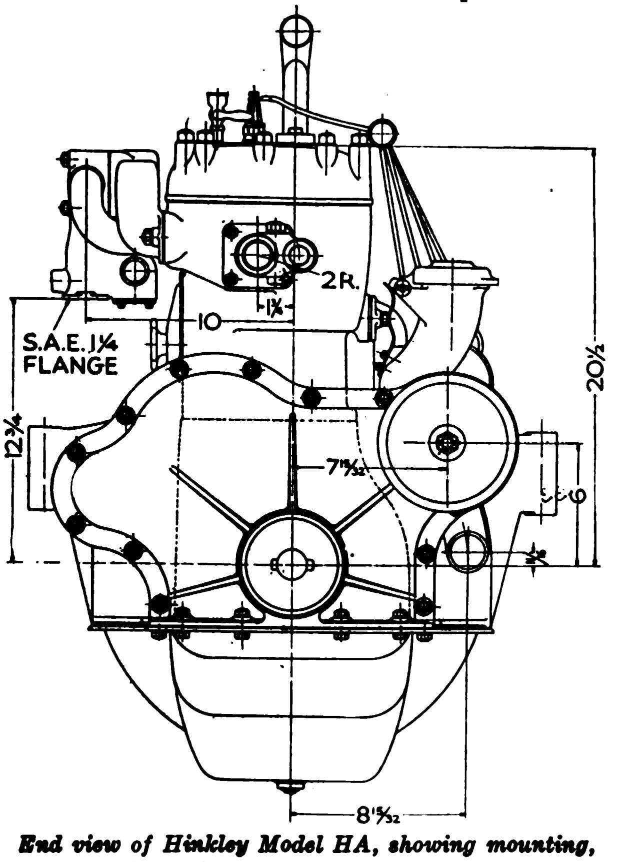
THE Hinkley Motors Corp., Detroit, is now entering commercial production with a line of truck and tractor engines, built around the standards of design and workmanship utilized in the manufacture of the Class B Government engine. Having, through its experience with the military truck engine, reached the conclusion that this design represents the best in construction for heavy-duty automotive purposes, the Hinkley corporation will manufacture this same type of engine under the name Hinkley-Class B. In addition, the models HA and HAA are built along the same lines and show the same characteristics with reference to appearance and performance.

This gives a line of three engines, all of similar characteristics, rated at 55 hp. at 1400 r.p.m. for the Hinkley-Class B, 45 hp. at 1500 r.p.m. for the HA, and 35 hp. at 2000 r.p.m. for the HAA. These engines are respectively suitable for 4 to 6-ton, 3 to 4-ton, and 1½ to 2½-ton commercial vehicles, or 4-plow, 2 to 3-plow, and 1 to 2-plow farm tractors.

In following the high standards of design and workmanship laid down by government specifications on the Class B military engine the Hinkley corporation has taken a step which has been predicted as a result of the war experiences. In designing this engine for the Government, the matter of price did not enter as a primary consideration, but the performance and life were made the prime factors. It is around the idea that the motor truck business in this country would demand the same qualities for the commercial product that the Government has demanded for the war product that the Hinkley Motors Corp. has shaped its policy in producing this line of engines.



Right-side view of Hinkley Model HAA



End view of Hinkley Model HA, showing mounting, dimensions and timing gear case

The Class B military engine has been described frequently and is familiar to truck engineers. The Hinkley-Class B is similar in practically all respects to the Government design, the only changes being in manufacturing detail. The Class B is 4¾ by 6 in. with cylinders block cast. The turning effort of the engine is 3000 in. lb. at 1000 r.p.m. and the weight is 1040 lb., less carbureter and magneto. In all essential details the military design is carried out.

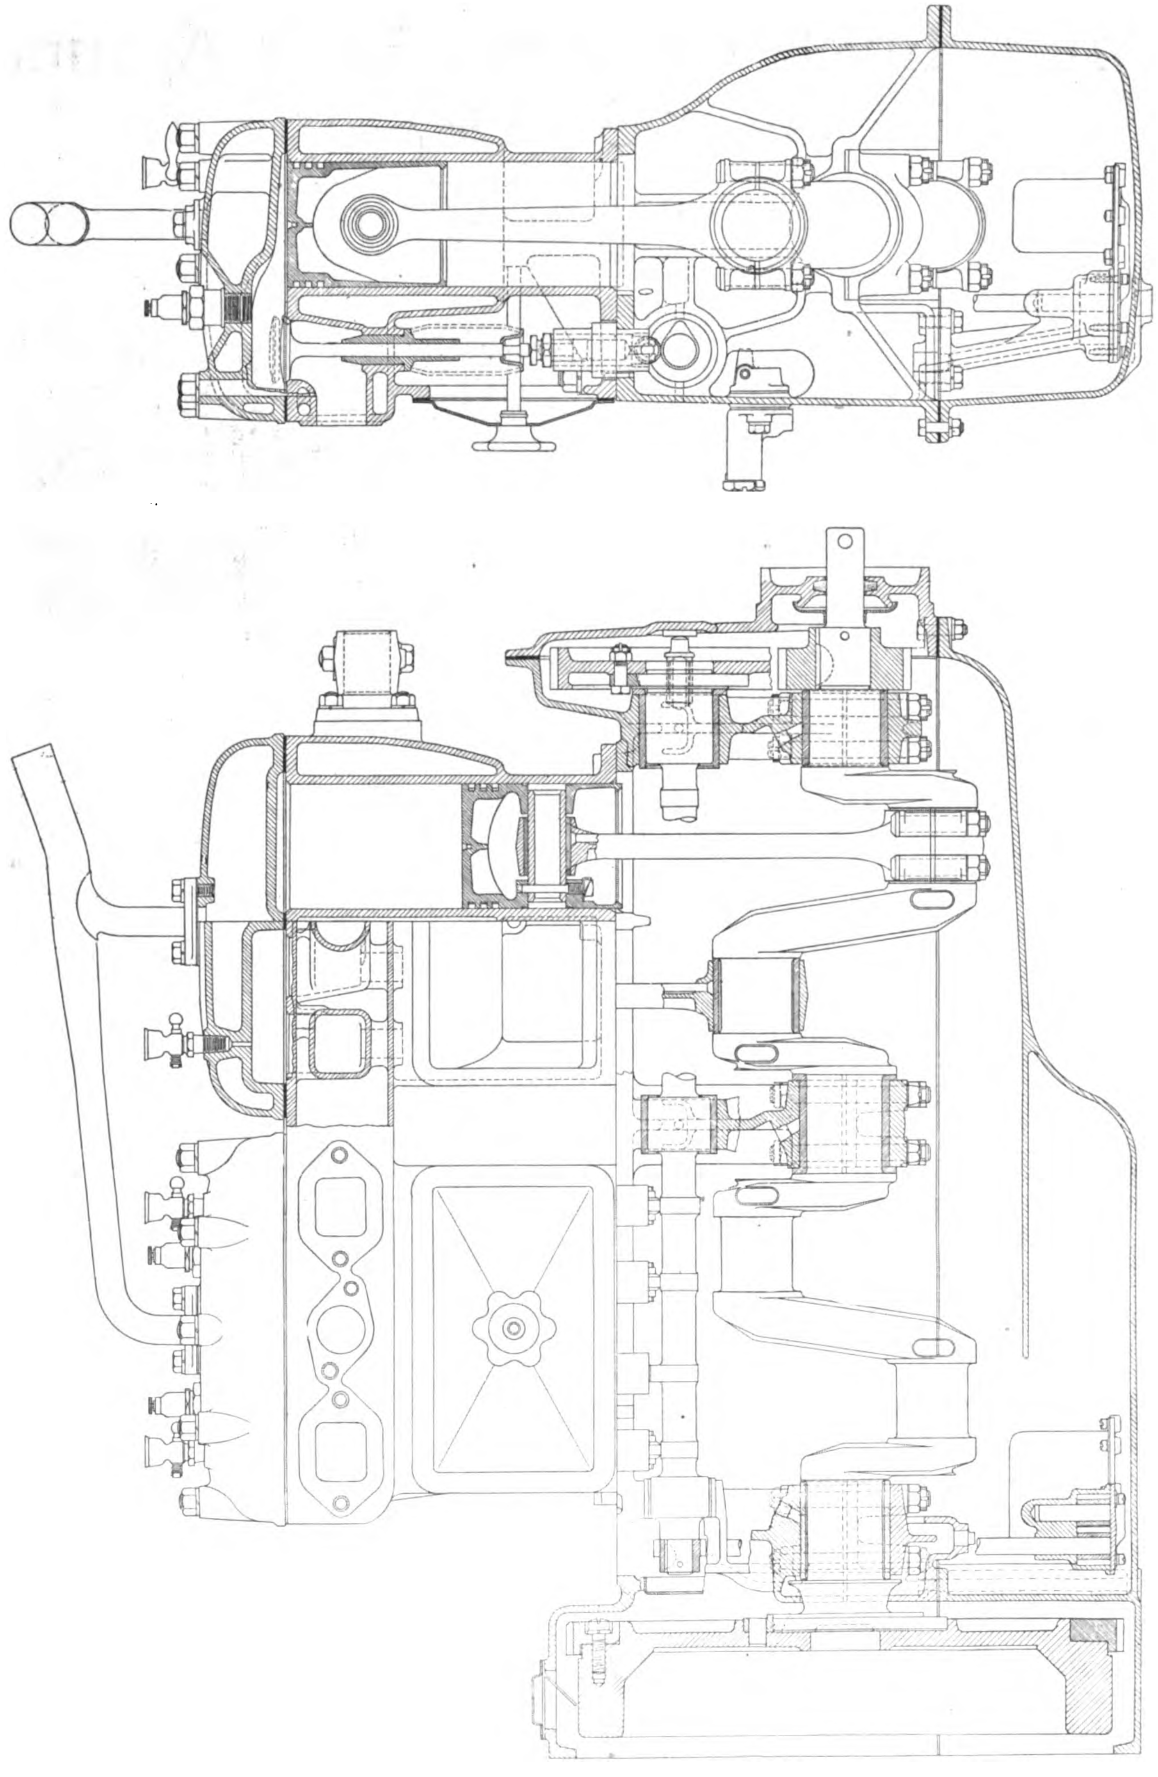
The Model HA is 4½ by 5½ in. and is otherwise identical, with the same rigid inspection safeguards as its predecessor, the Class B. The Model HAA is 3¾ by 5¼ in. and is also adapted for 4-in. bore cylinders, for the purpose of utilizing it in connection with maximum 2½-ton truck sizes, enabling truck manufacturers to standardize on one engine that will take care of trucks ranging from 1½ to 2½ tons.

The general description and specifications of these three engines are similar. The block cylinder castings have two detachable heads and are mounted on a cast-iron crankcase with a removable pressed-steel pan. The cylinders are L-head, all the valves being enclosed. All the engines have three-point suspension, the rear mountings being on the flywheel housing and the front mounting is a large-sized trunnion on the gearcase cover.

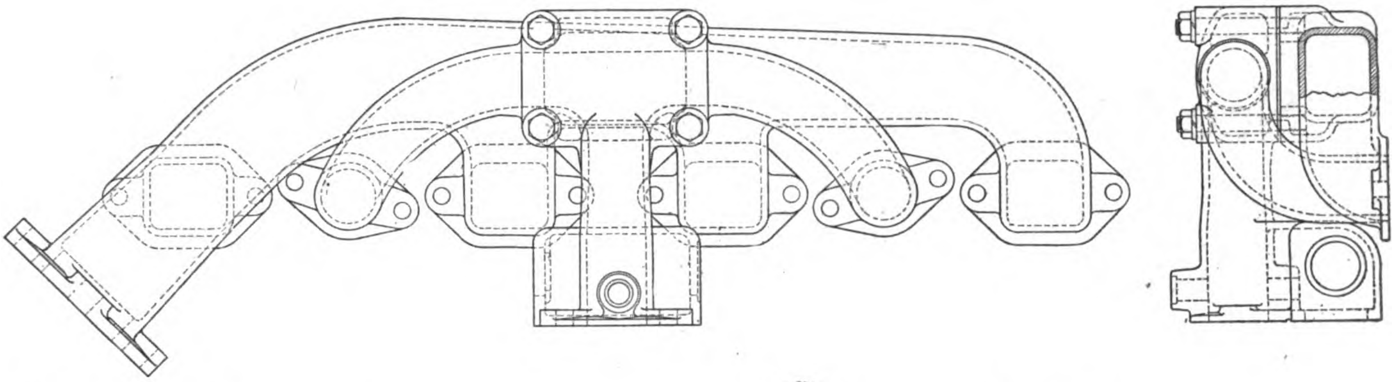
The piston displacements for the Model HA is 350 cu. in., and on the HAA, 232 cu. in. for the 3¾-in. bore and 264 cu. in. for the 4-in. bore. The valve diameters are 2 in. on the HA and 1¾ in. on the HAA. All the engines have the valves on the right side, with the manifolds on the same side as the valves. The general characteristics of the engine are such that they all show better than 0.6 lb. of gasoline per brake horsepower hour under maximum load conditions.

One of the characteristics of the Class B engine was its heavy crankshaft, and this same feature will be followed in the smaller models. On the Model HA the crankshaft is 2⅝

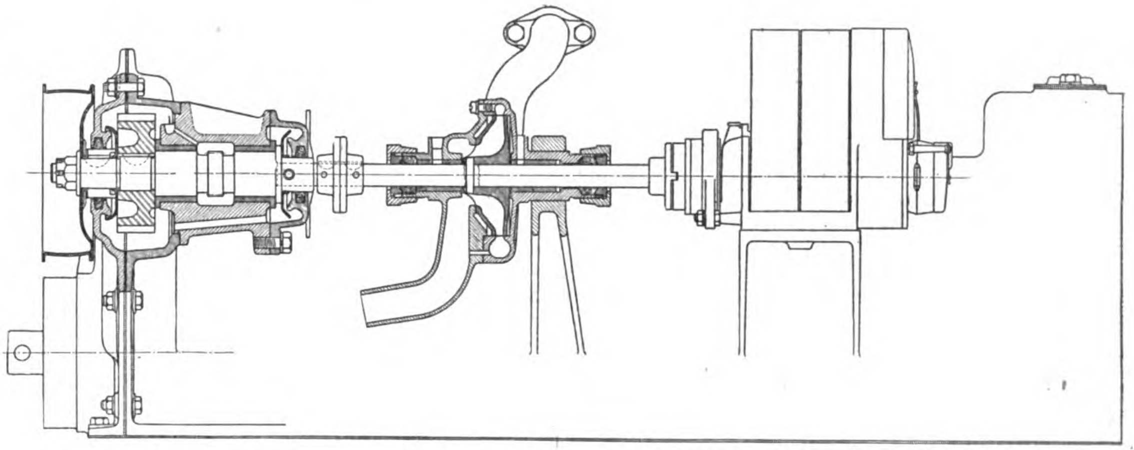
New Hinkley Engine for Truck and Tractor



This engine is built around the standards of design of the Class B government type and is especially adapted for heavy-duty purposes



Exhaust and carbureter manifold assembly on new Hinkley engines

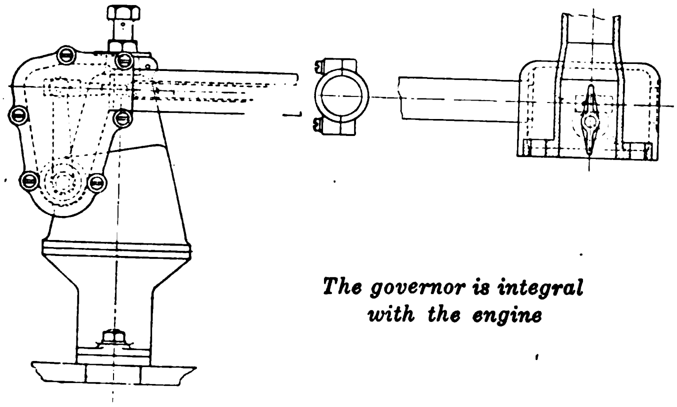


Water pump and magneto drive of Hinkley engine

in. in diameter at the main bearings and 2¼ in. in diameter at the connecting-rod bearings. The lengths of the main bearings on this model are: Front, 2⅛ in.; center, 3⅛ in.; rear, 3½ in. On the HAA engine the crankshaft is 2¼ in. in diameter at the main bearings and 2⅛ in. in diameter at the connecting-rod bearings. The main bearing lengths are: Front, 2¼ in.; center, 3 in.; rear, 3 in.

The camshafts are carried on three large collar bearings through which the camshaft may be withdrawn, leaving the bearings integral with the case. The cams are designed for the roller type of lifter and these are made of large size, as shown in the sectional illustration, to withstand wear. The large valve stems and heavy spring characteristics of the Class B military engine are followed on these two smaller models, and the same locking systems on the valve stems are utilized.

The connecting-rods on the Model HA are 12 in. in length; on the HAA they are 11½ in. long, and all are of the four-bolt construction, having alloy steel bolts to hold the caps in place. The rod is designed with the web in the center, and the upper rod bearings on the small engine are 1⅛ in. in diameter by 1¾ in. long, and on the larger engine 1¼ in. in diameter and 1⅞ in. long. Both engines are equipped



The governor is integral with the engine

with five-gear trains in front and have the camshaft gear bolted to the camshaft flange with four alloy steel bolts. The idler gear runs in a double, babbitt-lined bronze shell bearing. Provision is made on the engine for lighting generator and starting motor, the make being optional.

Pump water circulation is used, a centrifugal pump with one connection to the cylinder being employed. The water outlet header has two connections of tubular construction, to secure the proper water distribution to each cylinder group. To assist in vaporizing the fuel the engines have the hot-spot manifold design, assisting in completing vaporization and helping to minimize crankcase dilution. Another feature of the construction is the surplus of metal around the head bolts, preventing possibility of unequal pressure on the head gasket when tightening the bolts.

A full force-feed lubricating system is employed with the oil pump submerged in the oil pan, the latter being integral with the crankcase so that the crankcase can be dropped without disturbing the pump. The oiling system is so arranged that the lubricant feeds through a complete copper tubing system, clipped to the inside of the crankcase and carrying the maximum oil pressure to all the needed points. To maintain constant pressure, there is an automatic regulating relief valve. The oil gage is on the side of the crankcase and is of the conventional bayonet blade type.

Throughout the construction, sections are generous wherever there is any unusual stress. This is particularly noticeable in the pistons, which are extra heavy in section to enable the heat to be rapidly carried to the jacket wall with the greatest amount of speed to insure cool heads. Another provision for safety is in the extra large anchorage plate on the front of the cylinder block to take care of any standard make of fan. The plate is bolted to a square pad on the cylinder block in such a way that there is more than enough metal to prevent the breaking of water jackets.

There has been no departure from conservative practice throughout the engine, but, as in the case of the Class B military truck engine, the best-known principles of design have been employed without any shaving of specifications to cut production costs. The Hinkley Motors Corp. is in a position to deliver immediately the military Class B truck engine type, and within a short time will be in a similar position on the HA and HAA models.

See Great Future for Lighter-Than-Air Machines

Their Use Soon for Aerial Traffic Discussed by Engineers at S. A. E. Aeronautical Session—Planes Should Land in and Leave Small Spaces

OF all speculations as to the future of aerial traffic nothing seems as certain as that lighter-than-air craft of very large size will be tried out as long distance passenger carriers within a short time. That airplanes of anything near the load capacity of these ships will be built in the near future seems extremely unlikely.

These views, held by many whose opinion is entitled to respect, were emphasized again in two interesting papers read at the S. A. E. meeting in New York March 5. C. H. Day, of the Standard Aircraft Co., discussed the future of the airplane, pointing out constructional changes which would be necessary to adapt the war-developed plane for commercial usage, and Ladislas d'Orcy in a following paper gave much information as to recent performance of airships, showing how their development in war has been little less than that of airplanes.

Day anticipates a very important change in airplane construction which will permit the motor power to be used in a variable direction so that lift can be obtained at a lower speed than that at which the machine will fly when the whole power of the propeller is applied horizontally, or nearly so.

He considers that the practical use of an airplane and its safety depend in large measure upon ability to alight upon, or to rise from, a small area. At the present time 45 m.p.h. is about the minimum landing speed of a fairly fast plane; it might be possible to devise braking systems which would permit a machine to be pulled up quickly after landing, but such would be of no assistance in getting off the ground, and there is not much point in enabling a machine to land in a smaller space than it can get off from.

Vary Application of Power

To vary the direction of application of power Day suggests two possibilities, one the use of a propeller which can be inclined variably to the center line of the plane, the other variable wing surfaces which could be changed at will either as to area or inclination.

He points out that these are mechanical problems which should not be impossible to overcome, and that short distance flying, especially near cities, will only be fully practical when the plane can land on a city lot or even on a roof. For mail service especially the necessity for landing and transferring the load a good many miles from its ultimate destination is a serious handicap.

Day considers it unlikely that practical airplanes with a capacity for more than twelve passengers are to be expected till the art is much further advanced, but he has a strong belief in the small machine once the landing difficulty is overcome.

He voiced an opinion shared by many engineers, namely, that to make flying commercial the machine as a whole, and especially the engine, would have to be less delicate. He suggested that the air-cooled engine, so far, had always been developed with an extreme of lightness, so that it would be much lighter than a water-cooled engine of corresponding power, and that it therefore seemed likely that much could be done with air cooling. An air-cooled engine weighing the same for its power as a water-cooled motor, plus its water, ought to be, he said, much stronger and more durable, while also being cheaper to manufacture.

Day also believes in the evolution of twin-engined planes, even for small sizes. For one thing a plane with twin engines can be manœuvered on the ground by the pilot without the help of a gang of men to set it facing the right way. Also it is safer, if so proportioned, that it can just fly with one motor alone.

He suggests that twin motors of as low a power as 60 hp. would be valuable for single-seated "sportsman" types. For large machines he considers twin motors advisable because of their safety and also because of two motors arranged in nacelles the fuselage can be much better arranged for passengers and also protected from much noise and all thrown oil.

The following quotations from the paper cover these leading ideas of the authors:

"The commercial airplane of the future will be used for sport and the carrying of mail, passengers and express. All of these things are now being accomplished successfully but in a limited manner, and to what extent the field of usefulness will be increased depends largely upon the ability of engineers to develop machines better suited to this purpose than those that at present exist.

Factors to Be Considered

"Of paramount importance are the questions of safety, low initial cost, low cost of upkeep and low cost per ton-mile. A great deal of attention has been given to devices to increase the stability of the airplane with an idea that this will greatly increase its safety. I do not believe that the development of such devices will greatly enhance the future of the airplane. The ease with which pilots have learned to fly existing training machines would certainly indicate that the stability of these airplanes is sufficient for present needs, and investigation will show that the majority of accidents have been due to either collisions in the air or bad landings, and not through any inability of the pilot to control the actions of the machine. The stability of these machines can be increased to almost any extent desired at very little sacrifice of efficiency. In fact, it is perfectly feasible for any aeronautical engineer to design a machine of any type with the surfaces proportioned and arranged so that the machine will be self-righting under all conditions; will not tail-spin unless forced into it, and will come out of a tail spin of its own accord. By fixing the rudder on such a machine, it will fly almost indefinitely with all controls released and in case of motor stoppage will assume a natural gliding angle and maintain that gliding angle until it reaches the ground. I might add that there are absolutely no mysteries connected with the design of a machine to accomplish these results, and while riding as a passenger in such a machine two years ago I personally saw all of these.

Must Land in Small Space

"To my mind, the most important development for the future will be that which will enable airplanes to land in extremely small fields, or literally, in a man's back yard, and this must be obtained at not too great a sacrifice of high speed. At the present time the load carried on an airplane which has sufficient reserve power for safe flying is about 20 lb. per hp., and a speed range of from 45 to 90 miles per hr. is now obtainable with this loading. It would, therefore, seem that the future airplane should be able to maintain a high speed of 90 miles per hr., speed being one of the main advantages of the airplane over other means of travel.

"Among the possible means for reducing landing speed without sacrificing the high speed is the development of more efficient airfoils, devices for increasing the camber of the airfoil in landing, increasing the surface of the main planes, and possibly the development of an angular propeller thrust or auxiliary propeller to reduce the load per square foot of surface. Landing gears having greater shock-absorbing qualities to allow of stalling into a field from a greater height than is now possible would also help greatly. Airfoils having a high lift at high angles with low resistance at low angles, and which still maintain a good lift-drift ratio at normal angles, greatly reduce landing speeds and usually allow of maximum climb at low speeds. It is very probable that the efficiency of the airfoil will be increased to such an extent that any increase of camber would be of little benefit.

"With relation to the use of angular propeller thrust or auxiliary propellers, it should be noted that with machines carrying 20 lb. per hp. not more than 50 per cent of the power is necessary for sustained flying at very nearly the airplane's lowest speed. It certainly would be highly advantageous if the 50 per cent excess horsepower available at this point could be utilized as a vertical component to reduce the loading per square foot and thus reduce the landing speed.

Cost Is Next to Safety

"Of next importance to safety is cost. There is no doubt in my mind that the future airplane can be greatly simplified and thus greatly reduced in initial cost, and at the same time be made sufficiently durable so that the cost of upkeep will be a little more than that of an automobile. Most airplanes at the present time, whether they are manufactured in small or large quantities, are practically a hand-made product, and this must be eliminated in the future. The concentration of efforts toward enormous climbs and speeds for military purposes has resulted in extremely complex structure, delicate workmanship and expensive materials. However, the military airplane has developed many new materials which will, in the future, result in not only more efficient machines but great reduction of initial cost. The use of waterproof veneer is of utmost importance and if judiciously employed will do away with fully 50 per cent of the number of small and intricate parts. In the past little attention has been given to the interchangeability of parts, it having been the custom to design each part for the particular purpose for which it was desired without regard to its use for different purposes. Proper attention given to this matter would go far toward eliminating the manufacture of airplanes by hand and would reduce both the initial cost and the cost of upkeep.

"One of the airplanes now doing very successful work which has a range of 540 miles at 90 miles per hr. and carrying a load in addition to pilot and passenger of 2000 lb., costs 20 cents per ton-mile for fuel. Reducing this range to 270 miles and utilizing the reduction of the necessary fuel for the carrying of additional load, brings the cost of fuel to 13 cents per ton-mile. It will, therefore, be seen that proximity of landing fields has much to do with the reduction in cost of the operation of an airplane.

Upkeep an Important Item

"Durability has been of very little importance, but for commercial purposes the upkeep becomes an enormous item of cost. This is true not only of the airplane itself but also of the engine propelling it. Both the initial cost and the cost of upkeep are about equally divided between the engine and the airplane, and this engine cost must be greatly reduced. In the most efficient weight-carrying airplanes of to-day with a loading of 20 lb. per hp. the structural weight of the airplane itself is about 30 per cent of the weight of the machine fully loaded, and the weight of the engine is about 20 per cent of the total weight, leaving 50 per cent for fuel and useful load. For a range of 600 miles, the weight of the fuel is about 20 per cent, leaving about 30 per cent for useful load. Improvements in the airplane structure will greatly reduce the percentage of structural weight and will allow the use of heavier engines with corresponding reduction of cost. However, it is very doubtful if the trend of engine design will be in this direction, as efforts will be concentrated toward the increase of the percentage of useful load carried.

"As to the particular type of airplane to be used for commercial purposes, the tractor would seem to be most advantageous. Inasmuch as safety is of the greatest importance and most wrecks occur in landing, the pilot and passenger should be located well to the rear of center of gravity, so that the heavier parts of the machine, such as engines, etc., may reach the ground first, as they are much more capable of absorbing the shock than is a human being. The two classes of accidents which are most common to the airplane are wrecks due to bad landings and nose dives resulting from engine stoppage in climbing out of a field when the altitude is not sufficient for the machine to recover.

Multi-Engined Machines Safer

"It would also appear that multi-engined machines will not only add to the safety of the machine but also reduce the cost per ton-mile and by decreasing the liability of breakage thus reduce the cost of upkeep. You will probably assume that the use of multi-engines means an increase in the weight of the power plant, but on investigation it will be found that the opportunities given for the reduction of the structural weight due to the distribution of loads are so great that the structural weight of the machine will be decreased in far greater proportion than the weight of the engines is increased.

"I would like to point out at this time that the greatest assistance which can be given the airplane engineer in the design of commercial airplanes is the development of suitable engines, of which there are very few in existence at the present time. As with the airplane itself, all attention for the past few years has been given to engines of very high horsepower and extremely light weight, with initial cost and cost of upkeep as purely secondary considerations. It is probable that some of the existing airplane engines, if built in enormous quantities, could be produced at a reasonable cost, but the production of commercial airplanes is, at the present time, somewhat limited, and the growth of the industry must necessarily be gradual. It would, therefore, seem that the production of existing type of engines will not be sufficiently great to get the cost down to a reasonable basis. Engines of medium horsepower would be highly advantageous for smaller types of commercial planes, and a very satisfactory sportsman's machine of the twin-engined type with units of 60 or 70 hp. would be a desirable product, and it should be possible to produce such engines at a comparatively low cost. For this type of machine the air-cooled type of engine would be particularly desirable, inasmuch as the engine may be of comparatively small size and small bore and may be exposed in a manner which would not be practicable in a single-engined type. All air-cooled engines which have previously been brought out have been of a type in which efforts have been made to reduce the weight to an extent far beyond that of the water-cooled type. I believe that an air-cooled engine of medium horsepower, weighing the equivalent of a fully equipped water-cooled engine, including radiator and water, would make an efficient power plant, and one which could be produced at very low cost."

Promise of Lighter-Than-Air Machines

D'Orcy's paper showed that with improving mechanical structure we may expect the lighter-than-air machine to increase greatly in size and capacity beyond present limits. His contention was that the fundamental facts proved the advantage of very large airships, because the lifting power increases as the cube of the dimensions, while the resistance to passage through air increases only as their square.

This means that as an airship grows larger the weight of the engines necessary to drive it at a chosen speed becomes an ever-decreasing proportion of the total lifting power. This fact is also of value in showing that as ships increase in size there is less necessity for using very light and costly metals in their construction. Beyond a certain size of rigid type it would not pay to use aluminum alloys.

Another expectation of the author is that helium, having a lifting power not greatly inferior to hydrogen, will be available in adequate quantities, and it has the enormous advan-

tage of being absolutely inert, that is to say it is as uninflammable as nitrogen.

D'Orcy said that airships of existing types could be depended upon to cross the Atlantic in 60 hours carrying a substantial load. He said that the famous British engineering firm of Vickers, Ltd., one of the largest concerns in Europe, had already announced that they would soon commence a regular service between England and America on a 60-hour schedule. They plan to run two ships in each direction each week and estimate that the adventure will be profitable at a fare of $250 per passenger.

The rapid increase in *useful* load capacity of airships is shown by comparative figures for two typical German ships. In 1914 a large German ship had a gross lift of 30 tons and useful lift of 8.5 tons. A larger ship of similar type built last year has a gross lift of 66.6 tons—little more than double—and a useful lift of 39 tons—nearly five times.

This means that with very large ships passengers would be able to be accommodated in real comfort, be properly housed and fed and generally as well looked after as on an ocean liner and yet make the trip at three times the speed of the fastest of them.

It is in such long-distance trans-oceanic work that d'Orcy sees the greatest immediate future for the airship. Also the engine power required for a given speed as the size of the ship grows means that with every increase in bulk the cost of transportation per unit of useful load will decrease.

Theoretically, almost the reverse is the case with an airplane whose lifting ability as well as its translational speed has to be provided by engine power. It therefore appears probable that airplanes and airships will develop independently for different classes of usefulness and have fields almost as dissimilar as those of the railroad and the steamship. Competition between the two types of aircraft is not to be expected; co-operation is more likely, the one offering the speediest long distance transportation and the other the fastest form of short distance travel.

A very useful paper of a totally different character also read at the meeting was one on airplane radiators by Archibald Black, U. S. N. This paper contains a great amount of carefully collected data dealing with the efficiency of different types of radiator, the effect of different mountings on the airplane and numerous other vital factors.

This paper, being mainly composed of collected facts, is almost impossible to digest. The uppermost thought after hearing it is that much still remains to be discovered before the last word on the subject can be written. In a general way the conventional mounting on the nose of the fuselage or nacelle appears the most efficient and satisfactory, but a good deal of premise lies in the types of radiator which are built into the wings so as to make almost an integral part of the wing surface. The author pointed out that methods of controlling motor temperature were only partly developed and his comments suggest that there is a field for efficient automatic control, the automobile form of thermostat having some disadvantages. The principal tabulation of data from this paper is reprinted on pages 592, 593 and 594.

Egotism in Business a Grave Error

(*Continued from page* 577)

This is one of the most dangerous mental attitudes that a concern can take, because while it stands still the rest of the world progresses around it, leaving it to go relatively backward. A consulting engineer who is well up on existing trends of developments can readily cure this. A concern which calls in a consulting engineer regularly will never take this mental attitude. Year by year better products are going to be turned out and not in our generation nor the next will the ultimate in any man-made product be reached.

The consulting engineer is often in a position to interpret complaints from customers and service stations. The plant engineer may fail to read between the lines and see how these complaints bear relationship to one another and perhaps vitally affect the product. The consulting engineer who is trained along these lines can readily be of material benefit in this respect alone.

In the creation of new designs the broad vision of the consulting engineer is most necessary. When a plant engineer sets out to design something entirely new it is difficult for him to remove from his mind problems with which he has been wrestling daily.

The consulting engineer on the other hand is able to sketch his mental picture of a future design from the far broader viewpoint of a man who has continually surveyed the entire field. He can sketch the outline and the main points in a way which will bring home vividly to the plant engineer the general state of the art and the plant engineer from his detail experience can fill in the minor points, and perhaps in the light of his intimate knowledge, suggest improvements which will go far to improve the quality of the new product. The consulting engineer and the plant engineer make an ideal combination on the creation of new designs.

In checking and testing work, the services of the consulting engineer are also practically indispensable. It is impossible for a man who has done a piece of work to check it properly by himself. He must call in an outside man. The plant that fails to do this is laying itself open to great criticism. It is a vital point that errors which may be found in checking or testing may be found early and before production plans are too far advanced.

After having made his test and done the checking the consulting engineer is in a position to suggest improvements which will tend to make the product better and these can be discussed in conference by the various department heads of the plant and the consulting engineer.

It must be remembered that the consulting engineer is not the man to make the final decision. He is the man to make the suggestions and give the reasons for his suggestions. It is up to the plant department heads and to the plant executives finally to decide on what is done, but by his presence at conferences the consulting engineer is able to inject lines of thought into the consultation which perhaps would never enter the mind of anyone connected with the plant. He brings into the discussion the broader thoughts of the outside world, which must be considered if the plant is going to successfully produce products that are going to be broadly sold.

The retention of a consulting engineer can never be a reflection on the personnel of an organization or on its product. Nor is the consulting engineer failing in his duty when he is not able to suggest any practical improvements over what has been reached in the plant. If he cannot do so in view of his broad experience and if he is the proper man for the job, his confirmation alone is worth much to the entire manufacturing organization.

The name of the consulting engineer need never be mentioned in connection with its production. He is a confidential adviser and in much the same way as the auditor or legal counsel, who are called in by concerns of every type. As a check on the ideas of the organization he can be invaluable and his value is largely determined by his broadness of vision, by his wide range of experience and by his diligence in securing, cataloging and keeping at his fingers' end a wide and complete range of information.

Campbell All-in-Mesh Gearset

Utilizes Tilting Key for Locking Layshaft Gears

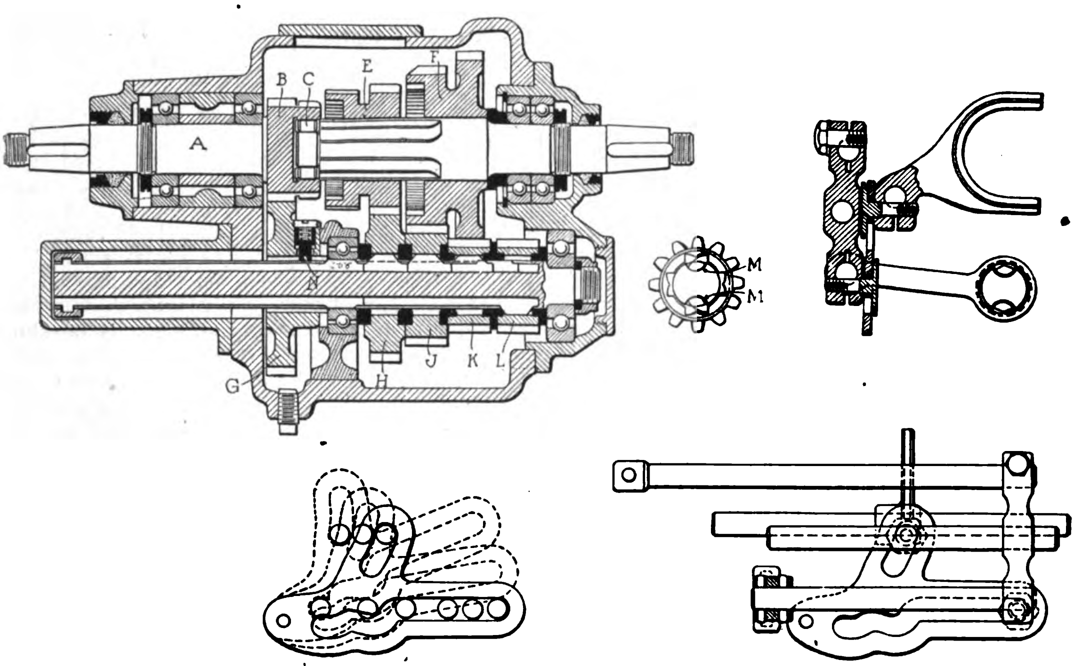

Fig. 1—Cross-sectional view of the four-speed Campbell gearset, with details of layshaft gears, cam plate and shifting mechanism

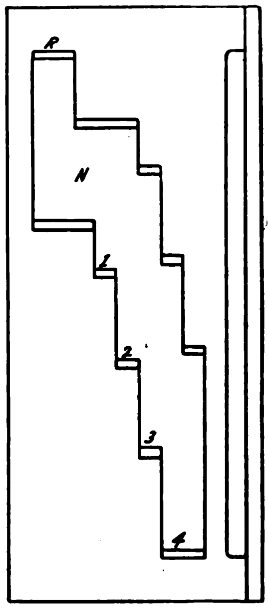

Fig. 2—Change speed lever plate used with Campbell gearset

THE Campbell all-in-mesh type of gearset is one wherein the gears are constantly in mesh, with the countershaft or layshaft gears locked internally by what is termed a rolling key. Thus the different speeds except high gear are secured by shifting the key under the desired gear.

Inasmuch as the clutching devices are located immediately under the layshaft gears and not at the sides, the Campbell gearset is shorter than other in-mesh types, resulting in but 6 in. center to center between bearings on the layshaft, and this on a 2- to 3-ton four-speed truck transmission. Model 50 is illustrated. One of these has been in use for several months in a 2-ton Garford truck at the Great Lakes Naval Station, where it has been subjected to much severe handling. A representative of the Class Journal Co. drove this truck over all sorts of roads, bringing the gearset lever into the various speeds without touching the clutch pedal and regardless of engine revolutions.

Fig. 1 shows a cross sectional view of the four-speed truck transmission, together with details of the layshaft gears, cam plate and shifting mechanism. As shown the gears are in third speed. The primer shaft *A*, which connects to the engine or clutch shaft, is supported on two No. 308 single row ball bearings and carries on its inner end the constant mesh gear *B*. The latter is recessed for the solid roller bearing *C* supporting the mainshaft *D*, which is supported at the rear by a double row No. 308 ball bearing.

Shaft *D* is splined for the sliding member *E*, while the double gear *F* is spooled on the shaft and revolves with the shaft only when *E* is clutch-meshed with it, that is, the external teeth of the sliding gear are meshed with the internal teeth in *F*.

As shown, *F* remains idle, the shaft revolving inside of it. The bearing surfaces of this part of the shaft and inside the gear *F* are hardened. High gear is obtained when *E* is brought forward to clutch-mesh with *B* in practically the same way as is done in conventional gearsets, where the internally cut form of sliding gear is used in place of a dog clutch.

Immediately below gear *B* and in mesh with it is the constant gear *G*, an integral part of the layshaft. Adjacent to *G* is a single row No. 308 ball bearing, and then follow gears *H*, *J*, *K* and *L*, constituting the third, second, first and reverse speed gears respectively. The reverse pinion idler is not shown, but is just back of *K* and *L*, being the same length as these two combined. The bearing at the rear end of the layshaft is a single row No. 406. The bearings of the layshaft are close to the gears where the greatest load comes, minimizing the danger of a sprung shaft.

The gears of the layshaft except *G* are mounted on collars or rings acting as bearing surfaces. This can be a steel on steel construction or through brass bushings, balls, etc., as these bearings carry none of the load, but only the weight of the gear. The transmitting action is secured by simply sliding the key or keys along the circular longitudinal grooves

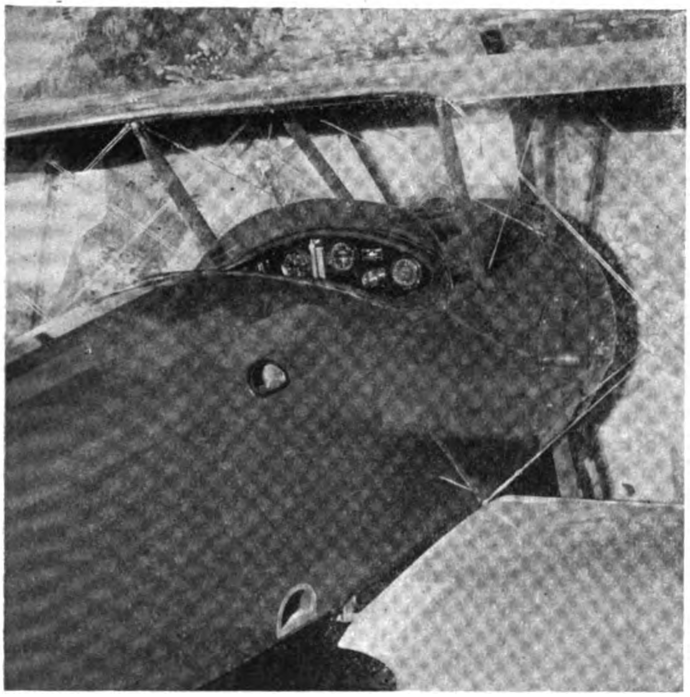
Complete shifting mechanism, showing single pull rod at top

Second Impressions of the Aeronautic Show

Some Mechanical Novelties Seen Among the Exhibit of Planes, Engines, Parts and Equipment—Educational Features Prominent—International Character of the Exhibition



Side-by-side seat of Thomas-Morse biplane. Note how instruments are arranged on cowlboard

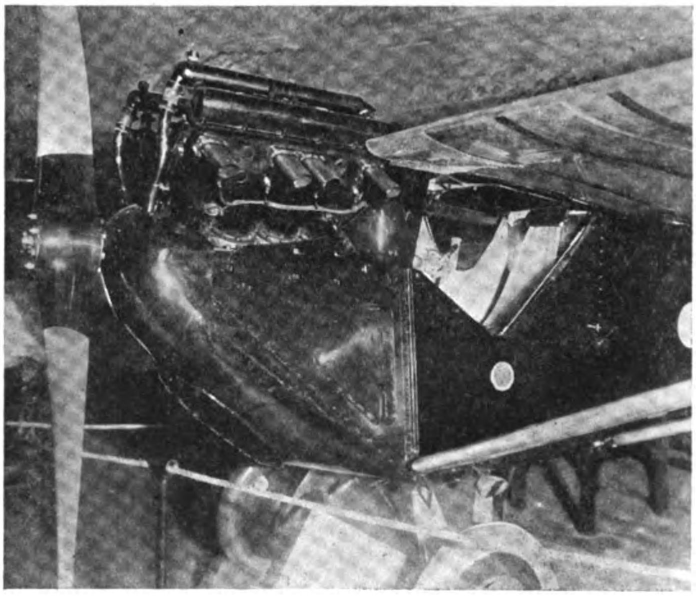
THE aeronautical industry is to be congratulated on the fine show it has staged at Madison Square Garden and Sixty-ninth Regiment Armory. There has seldom been an industrial exhibition in New York City with an equally attractive setting and as fully representative of the industry which fostered it. A very marked contrast is noticeable between this and the previous aeronautic show, in that the variety of exhibits is now much wider and the public is flocking to the show in much greater numbers.

There is more of an educational and less of a commercial aspect to the present aircraft show than to most other events of the kind. Among the great variety of types of airplanes shown, from the diminutive monoplane to the giant triplane bomber, war planes largely predominate. These have been the exclusive product of the exhibiting firms for the past several years, and they are the criteria of the achievements and the ability of their makers. Commercial uses of these same machines are being mentioned, which are said to call for only slight alterations in design, but one inclines to the belief that such machines would be subject to the same limitations as a passenger automobile converted into a commercial vehicle. Just what the chief points are in which a specially designed commercial plane would differ from a plane designed for military use it is hard to say. On first consideration one would be inclined to say that it would be lower-powered and therefore less speedy, because fuel economy is of greater importance in commercial work. However, some of the leading engineers in the aeronautical field take the opposite view, arguing that the only advantage of the airplane over competing systems of transportation is its higher speed, and that in order to justify its higher cost of operation this advantage of higher speed must be developed to the utmost.

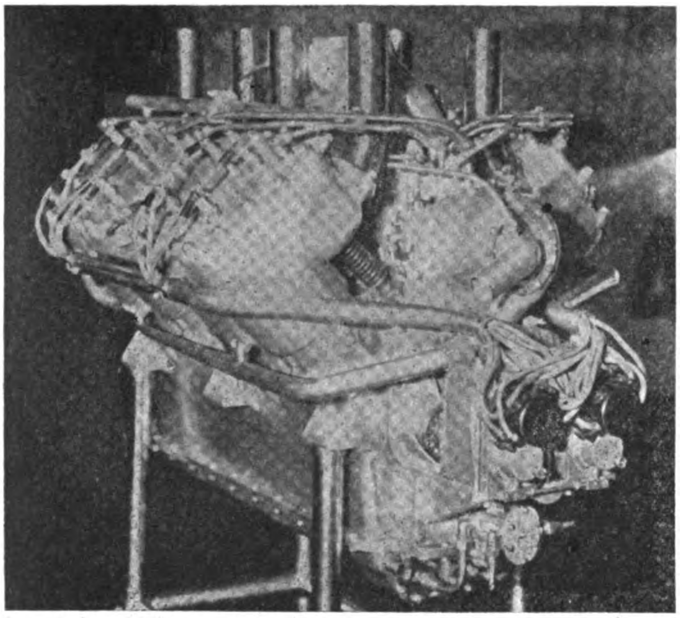
Practically every type of airplane and engine manufactured in this country during the war is being exhibited, in addition to some foreign material, both Allied and captured enemy. Most of the planes and engines have become well known to the public during the war and especially since the armistice was signed.

Super-Charging by Centrifugal Blower

At the stand of the Sturtevant Co. is seen an attachment designed to solve the problem of maintaining the power of an engine constant irrespective of altitude. This takes the form of a centrifugal blower attached to the end of the engine, for the purpose of forcing into the cylinders a greater charge than they could obtain by direct suction at high altitude. The blower is belt-driven and there is an idler pulley on the belt which is forced against it by a piston in a cylinder subjected to the atmospheric pressure, so that when this pressure drops the idler pulley is forced against the belt and causes the blower to run at greater speed. It is claimed



Front portion of Loening two-seater fighter. Note hammock seat and the position of the radiator indicated by the ring below the body



Thomas-Morse eight-cylinder engine

that only 5 per cent of the engine power is required to drive the blower. In view of the fact that at an altitude of 20,000 feet the power of an engine normally drops to 50 per cent, owing to the levity of the air, such a blower should be a useful attachment. The automatic belt tightener prevents an extra charge being pumped into the cylinders while at low altitudes and thus protects the engine from injury due to excessive explosion pressures.

That the design of the larger planes is still in its infancy is a conclusion arrived at after a comparison of the different types exhibited. The great Caproni, for instance, has a landing gear comprising two four-wheeled trucks, one under each of the engine nacelles, while the Martin bomber has a landing gear comprising four wheels mounted co-axially. A feature of interest noted on the Caproni, a night-bombing machine, is a series of electric projectors mounted under the rear edge at a downward inclination. They can be fed from a generator on one of the engines and should be a great help in making a landing at night.

Writing of the Caproni reminds one that there is at least one other Italian exhibit at the show, and a very impressive one, by the Ausaldo firm of Genoa. This is one of the largest Italian industrial enterprises, corresponding somewhat to Krupps in Germany and Schneider in France. There are also some French planes as well as the Handley-Page of British origin, but the Italian stands out among the foreign exhibits.

Among the new engines shown is the W. B. B. two-cycle. This is a 4-cylinder air-cooled machine giving 38 hp. It is a regular three-port type engine with the inlet manifold to the crankcase cast integral with this part. Having no valves and no water cooling system, this type of engine is a model of simplicity. Engineers would probably be inclined to question its fuel economy, and the manufacturers have sought to set at rest any doubts regarding this matter by displaying prominently a sign conveying the information that the fuel consumption is 6 gal. per hour. This engine is fitted to a small plane known as the Messenger, exhibited at the Garden by the Dayton-Wright Airplane Co.

King-Bugatti Engine

Considerable attention is being paid by visitors to the Duesenberg exhibit, which comprises the Duesenberg 800 h.p. 16-cylinder engine, the King Bugatti engine, as made by the Duesenberg Motors Corp., and a smaller 4-cylinder Duesenberg engine with 4⅜ x 7-in. cylinders. The unusual arrangement of the cylinders on the Bugatti attracts attention, there being practically two eight-cylinder vertical engines side by side, geared to a central hollow propeller shaft. This shaft is of such large size that it permits of shooting through it with a 1½-in. gun.

In the "Restaurant" of the Garden are shown a number of captured engines including a Mercedes 160 and an Austrian Hier. It is believed that the latter was designed by the Austrian racing driver Hieronymus, and that the name of the engine is an abbreviation of his

name. This engine has the vertical shaft for driving the overhead camshaft at the middle, between the third and fourth cylinders. A very simple compression relief is used on this engine. It acts on the inlet cams and prevents these from closing when set. It consists of two tubes running parallel with the tappet levers. There are slots cut in the tubes where the tappet levers cross it, and when the compression relief is not set the levers move into these slots and the valves can open and close freely. When the tubes are rocked around their axes, by means of a handle which joins to both, the valves are prevented from closing fully and the compression is relieved.

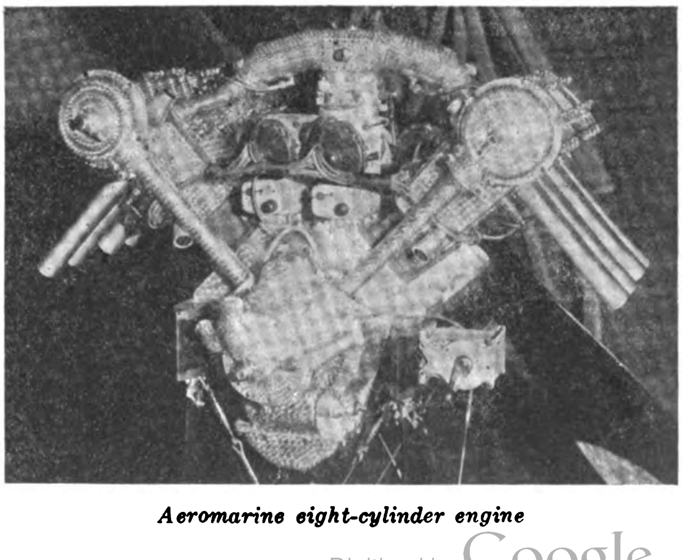
Two Aeromarine Engines Shown

The Aeromarine Plane & Motor Co., New York, exhibits two types of engine. One of these is a six-cylinder 4½ x 6½ in., weighing 375 lb. (405 lb. with electric starter and generator) and rated to deliver 130 h.p. at 1625 r.p.m. The main portion of the crankcase and cylinder jackets are cast integrally of aluminum alloy. The cylinder sleeves are alloy steel forgings, machined all over, to give a uniform wall thickness. After machining, the sleeves are heat treated and the working surfaces ground. The outsides of these sleeves are in direct contact with the cooling water over their entire surface. The cylinder-head gasket, of copper and asbestos, makes a tight joint against the top flange of each cylinder sleeve. The water joint at the bottom of each sleeve is sealed by a cork gasket, which allows freedom for expansion.

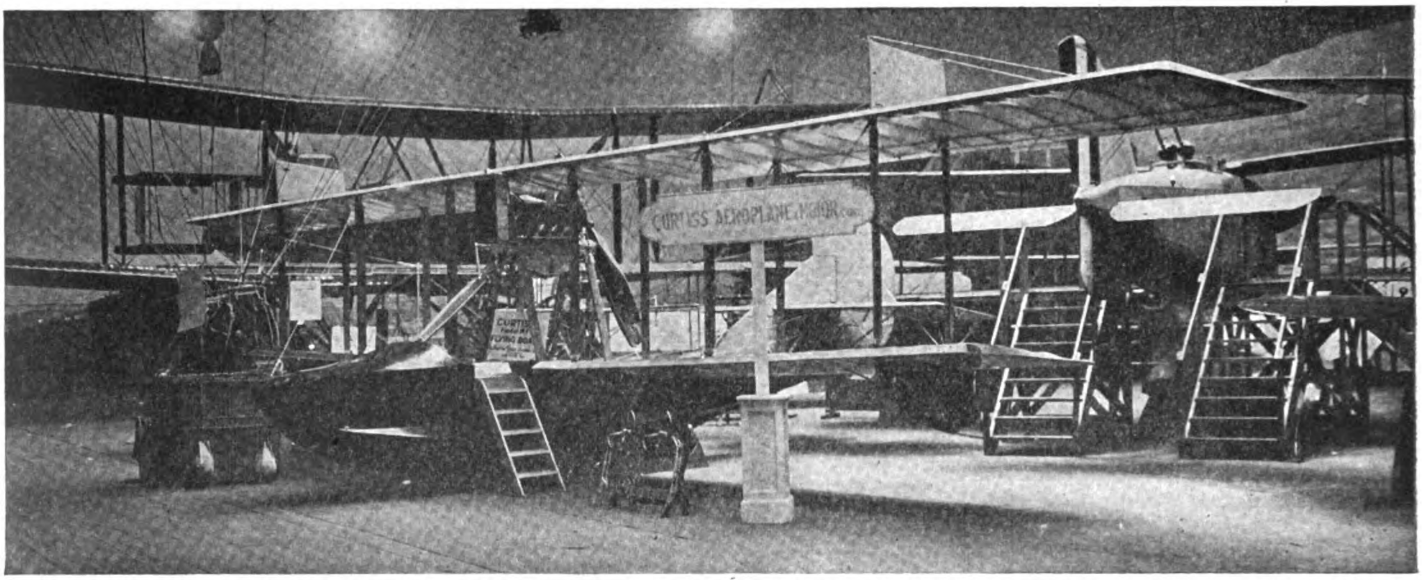
The cylinder head and valve gear form a self-contained unit, which can be removed from the combustion chamber, making it possible to remove the carbon or grind the valves. This head may be removed and replaced without re-timing the engine, owing to a special arrangement of the splined shaft which drives the camshaft gear. The head is of aluminum alloy with gray iron valve seats cast in position. The combustion chambers are machined. There are four valves for each cylinder. A special design of valve gear, embodying flat multiple leaf valve springs, effects a great reduction in length and weight of valves and valve levers, and also reduces the overall height of the engine. Each valve spring actuates two valves. There is an oil return passage from each end of the cylinder head to the crank sump. The whole valve gear is enclosed in a quickly detachable aluminum cover. A feature of the oiling system is that the oil, while passing to the auxiliary tank and from same to the engine bearings, is cooled by being passed through jackets on the inlet pipes.

The other engine of the Aeromarine Plane & Motor Co. is an eight-cylinder with two cast-iron cylinder blocks of four cylinders each, which are set to make an angle of 90 degrees with each other. It has a bore of 3⅝ in., a stroke of 5⅛ in. and develops 148 h.p. at 1300 r.p.m. Ignition is by two Dixie magnetos which are mounted side by side at the timing-gear end and are driven by two parallel shafts extending through the V, from enclosed gearing at the propeller end.

It seems that many little operations in an airplane which are somewhat dependent on the speed of the plane can be performed to best advantage by using a small propeller exposed to the air current created by the motion of the plane, serving as an air motor. Such a device, referred to as the Servo Motor, is being exhibited in two types. In one the power of the Servo Motor is transmitted mechanically by means of shafts and gear, while in the other it is transmitted hydraulically. In this case



Aeromarine eight-cylinder engine



This Curtiss flying-boat has been developed primarily for the use of sportsmen, and is finished exactly after the manner of a high-class motor car

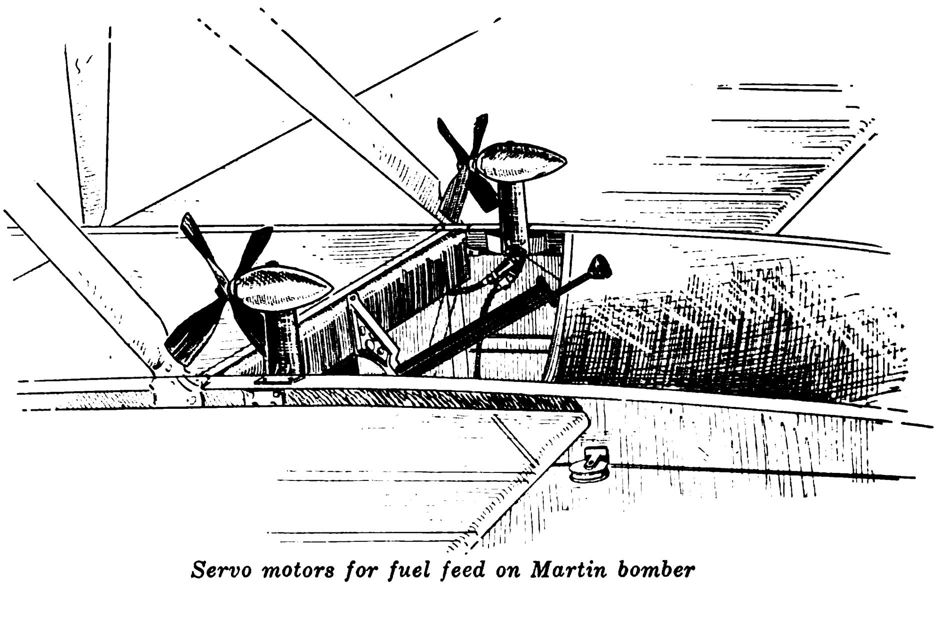
the propeller shaft carries a cam or an eccentric operating a plunger pump pumping oil. The oil may be conducted to any part of the plane and passed through a small hydraulic motor or turbine. The gear case and mounting of the small propeller are made in streamline form to reduce their air resistance to a minimum.

Indicating Instruments Exhibited

Indicating instruments form a most important item in the equipment of an airplane and they are shown in great variety. Instruments form the principal exhibit at the stand of the National Advisory Committee for Aeronautics, and there are also many exhibits by private firms. A recently developed instrument is the Vertimeter exhibited by the Aeronautical Instrument Co. It indicates the rate of climb or descent in feet per minute. It consists essentially of a spun copper tank of streamline form which is connected by means of a rubber tube to a U tube containing a colored liquid. There is a valve near the hose connection to the U tube through which air can escape from the tank to the atmosphere on ascent and pass into the tank on descent. The valve opening is so small that when the plane is either ascending or descending the pressure in the bomb lags behind the change in atmospheric pressure, and the difference between the pressure within and outside the bomb will be the greater the faster the rate of climb or descent. It is this difference in pressure which causes the fluid to rise or fall in one leg of the U tube, the only one which can be seen by the pilot, and the stand of the fluid indicates the rate of climb or descent. The scale has a range from 2000 ft. p.m. rise to 3000 ft. p.m. drop and is provided with a check valve in the top which insures that in case the machine is being put through acrobatic stunts the liquid remains in the tube at the point corresponding to the rate of rise or descent just previous to the moment when the abnormal position of the plane caused the check valve to act.

A further exhibit emphasizing the educational character of the show is that of the American Steel and Wire Co. This comprises a wind tunnel in which are suspended an ordinary ¼-in. stranded cable and a sample piece of the company's streamline airplane cable of equivalent section. Both are pivoted at one point and the air resistance drags the free end around over a graduated sector, the full round cable, of course, much more than the streamline cable. At the moderate air speed maintained in the tunnel the round wire is said to have an air resistance of 12½ per cent and the streamline cable a resistance of only 1½ per cent. It is not stated what the percentage figures are based on, but probably, since the air resistance acts against the weight of the specimen, the latter is the basis of comparison.

It is not necessary here to enumerate the long list of parts makers prominent in the automobile industry who have been drawn into relations with the aircraft industry during the war and are exhibiting their aircraft parts. This list comprises especially makers of ignition equipment, carbureters, ball bearings and forgings. Considerable space is occupied at the show by exhibits of the various branches of the Government doing aircraft work. There are some very fine specimens of aerial photography and map-making.



Servo motors for fuel feed on Martin bomber

Campbell All-in-Mesh Gearset

(*Continued from page 596*)

M in the shaft until they slip under the rings of the desired gear, after which the key automatically and positively rolls into contact with one of the broached openings on the inside of the gear. This action is shown in the cross section view of the gear in Fig. 1. One key takes the load and the other the backlash.

The keys are shown in Fig. 3 and constitute the chief feature of the transmission. In the truck job, the keys are drop-forged from ¾-in. round stock, with 1-in. face. Referring to *A*, Fig. 3, it will be noted that the portion *O* is made 1/16 in. larger than the true radius of the ¾-in. circle. Also the key clears the shaft by 1/32 in., that is, the face of the key must roll in its groove 1/32 in. before it comes in contact with the gear.

The cams on the keys are made with sloping surfaces, which serve a two-fold purpose. One of these is to assist in the engagement of the gear and the other to release it.

The gears cannot take the full load until the key has been first rolled up into place in the gear. Therefore, instead of a shearing strain across the cam as shown at *B*, Fig. 3, the key is under compression, as shown by the dotted line in *C*, Fig. 3.

It is stated that the gears cannot become noisy, as the pitch line is not disturbed. Also the tilting key clutches the gear directly in the center and therefore the gear is not distorted on the shaft, though there may be considerable play between gear and shaft. The layshaft gears are reversible, that is, they can be turned completely around from their present position on the collars to distribute the wear.

In direct drive on high gear the keys are not used, for the clutching gear *E* meshes with *B* as in a conventional gearset. In high gear the following gears revolve: *B*, *E*, *G* and *H*, but *H* is only engaged with *E* for ⅛ in. This is done so that in shifting from high to third the gears are aligned and the key is so timed by the cam lever plate that it will not engage *H* until *E* is fully meshed with it. In going from third to second the key engaged in *H* releases first and then clutching gear *E* engages the double gear *F* for first and second speeds. Here again the key is timed so the gears are fully meshed before the load is taken. Thus there is no chance of stripping

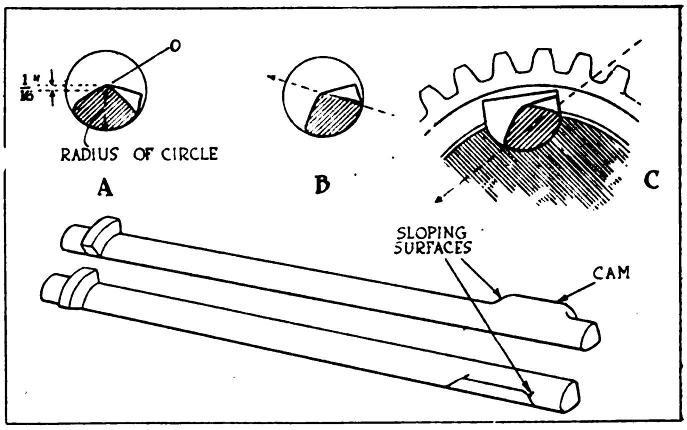


Fig. 3—Keys by which the transmission action is secured

the teeth in any of the gears, even with clutch in. The key shifting yoke at the extreme forward end of the layshaft has just enough play in it so the key slips into position under the selected gear, even though the driver attempts to make the shift very slow. This action is hastened by the sloping surfaces of the keys.

All gears are 6-8 pitch, with the following ratios: Reverse, 1 to 4.81; first, 1 to 4.00; second, 1 to 2.62; third, 1 to 1.50; fourth, 1 to 1.00.

The cam plate which works in conjunction with the key shifting mechanism makes it possible to use but a single rod between transmission and lever set. The cam plate also acts as a locking means for each speed. Thus, to pull the sliding gear out of high to another speed without operating the pull rod it would become necessary to shear the cam plate itself, which in a 2- to 3-ton job is ⅜ in. thick. With the cam plate layout it is impossible to get two speeds at one time.

Concerning lubrication, it is pointed out that the lubricant will last for a very long time, as the gears do not revolve constantly and therefore will not wear out the oil or grease. Also proper oiling of the gears on the collars is accomplished by the keys themselves, which act as pumps, carrying the oil back and forth in the grooves of the layshaft.

Tractor Problems That Are Awaiting Solution

(*Continued from page 583*)

two. The development of gearsets has not been as aggressively carried on as the development of tractor engines and a few other parts in which well-established companies with long experience have devoted their best efforts to the work.

Keeping dust out of engines is still a troublesome problem. Experiments have shown that improved crankcase breathers are needed. The conventional one will not keep out the dust in certain sections. The development of an air filter is being carried ahead, but this, too, has scarcely reached the parting of the ways, the branching toward water types and centrifugal types. Heretofore size has been too much of a factor. Some are very small but also inefficient. If the efficient filter must be large then let it be made adequately large to do the job.

There is a real lack of a rational tractor seat. The present seat, a hand-me-down from self-binder or mowing machine days, is not suitable. We place a good seat on a motor truck, or any kind of a car and then when it comes to a tractor we put on a seat intended for horse apparatus. Too frequently it is in the center of the machine, whereas it should be closer to the right side so as to afford a good view of the furrow or the other work. Too frequently it is not adjustable; it is not large enough, it cannot take a good cushion. Only one or two makers have as yet recognized that an adjustable seat is needed and that if the operator is to take the best care of the tractor and get the best out of it he should be made as comfortable as possible.

There is need for fenders and a platform for the operator. A tractor operator should not live in a cloud of dust when a standing platform and fenders will prevent it. The fenders are needed for safety. A good tool box should also be provided.

Tractor makers are recognizing that different soil conditions and different crop requirements call for changes in tractor features. The idea that one design will best fill every requirement is being exploded. The blanket tractor, that will do any job in any country in the world, is losing out. Some makers of creeper types have wider creeper belts for the rice country. At the same time that this has been done some wheeled types have been spending large sums vainly endeavoring to demonstrate that the identical size of wheel will do in the rice lands that does in the hard soil. A movement for differentiation has set in. One large maker has a new tractor which he has been selling in the East but not in the West. It is better suited to the hilly areas of the East than some of his older models.

It seems highly probable that different diameters and different widths of wheels may have to be sold with the same tractor, one for a hilly country and the other for a level area; one where the soil is hard when being cultivated and the other where it is soft. If wheel diameters were standardized how easy it would be to give the farmer what was best for him and what was also best for the tractor. Standardization may demand that we go a step further. Wheels may be made with standardized hubs so that one type of wheel can be interchanged with another.

Quantity Production Fours

THE evident demand for light-weight, high-quality cars has caused a noticeable tendency toward the increased production of four-cylinder cars. These are not merely brought out by a few scattered, unknown concerns, but some of the best known companies that have been successful in the four-cylinder and other fields are bringing out these cars.

As evidence of this there are the Essex brought out by members of the Hudson company, the new Cleveland brought out by officials of the Chandler company, the new little Overland which will shortly be in big production, and in addition there are reports that other prominent makers will soon be out with four-cylinder designs.

There have been a great many who have predicted the day of the four-cylinder car would come back and that one of the greatest results of the multi-cylinder popularity would be the increased demand for good performance from the four.

Certain it is that it took the multi-cylinder car to show us the creamy smoothness of power, which is so much appreciated by the owner.

Owners who drive their cars around the city for business purposes are demanding more and more a light-weight, high-quality vehicle, which is economical to run and yet which has all of the qualities of acceleration, good appearance and serviceability of the heavier and more expensive types.

Doubtless there are a number of advantages for the long wheelbase, heavy type of car for cross-country work. For the city, however, where the smooth pavements and all-around good traveling conditions exist, it must be admitted that it is folly to utilize the high-powered engine, which not only is wasteful from a fuel standpoint for such use, but which has an absurd ratio of weight to the service rendered. The influx of high quality, small, four-cylinder cars for all-around business use will be welcomed by those who have the true interest of the industry at heart.

Testing Airplanes in Flight

IN no other line of engineering work is the designer so in need of accurate experimental data as in airplane design. It is generally permissible to work with a liberal safety factor, which compensates for any inaccuracy in the calculations or assumptions. For good reasons the safety factor in aircraft must be kept low, and it is therefore of the greatest importance that the calculations for strength of parts, stresses on same in flight, power required for propulsion, etc., be of the highest possible degree of accuracy and based on thoroughly trustworthy data.

So far most of the constants and design factors to be used in airplane design have been determined in the laboratory. The properties of wing sections and of different forms of struts, landing gears and bodies are studied in wind tunnels in which air currents approaching in speed those of a plane in full flight are artificially produced. Power plants and propellers are tested on dynamometer stands, and to simulate as closely as possible the operating conditions in the upper atmospheric regions these tests are now being carried out in a vacuum chamber.

It was felt, however, that there were certain factors which an aircraft designer must know which can be accurately determined only on an airplane in flight. For instance, in a wind tunnel, lift and drift experiments can be made only on reduced scale models and there is then the possibility of committing errors in applying the results to the calculation of the full-sized machine.

Consequently, the Bureau of Standards in collaboration with the National Advisory Council has decided to develop recording apparatus for determining the engine torque, speed of revolution, plane speed, propeller thrust, angle of attack and inclination toward the horizontal. Some of these devices, as, for instance, a recording tachometer for the engine and a recording air speed meter, involve no special difficulties, but we are inclined to consider

the development of some of the others, notably the engine torque recorder and the propeller thrust recorder, problems of very considerable difficulty, on account of the great forces involved and the strict limitations on space and weight on an airplane. Yet we have not the least doubt that all problems will be fully solved and that the use of the apparatus when completed will yield test results that will prove of the utmost value to airplane designers. As all test records will be timed and the timing will be synchronous, it will be possible to study the inter-relations of the different power and resistance factors in flight.

Closed-Cab Advantages

THERE is no such thing as finality—there is always room for improvement and there is always a demand for any refinement which tends to improve the condition of the worker. New York and Chicago truck shows offered a concrete example of these axioms in the case of the enclosed truck cab, a feature of improvement which has been evolved from the plain board seat, the upholstered seat, the open cab, and now the cab which insures protection to the truck driver from the inclemencies of winter weather.

Closed cabs may cost more, but in compensation for their added cost they exercise a two-fold effect. In a material way they tend to increase the working capacity of the driver by reason of the bodily protection afforded, with a corresponding increase in the earning power of the truck to which they are fitted. In an abstract way the closed cab has its effect on the mental make-up of the driver. He starts on a long haul secure in the knowledge that he will arrive at the end of his trip dry and comfortable, his temper remains equable and the physical service he renders is but a reflection of his mental state.

Comfort in Tractor Operation

IT is undoubtedly too early to attempt to standardize tractor controls, but designers individually can strive to arrange their control levers, handles and pedals so that they can be conveniently reached and operated from the seat.

There are some good examples of control layouts, but there are even more examples of poor ones. There is less need for standardized control than on automobiles, as there is no danger of a driver having become accustomed to one form of control meeting with an accident while operating a tractor in which the control devices are differently arranged. Tractor speeds are too low for this.

But the pedals and levers should be within easy reach of the driver, their range of motion should not be excessive, nor should the effort required to operate them such as to cause fatigue to the driver.

Another point that bears directly on the comfort of the driver is the type of seat and the provision for foot rests. The seat should, of course, be spring supported, so that the driver is to a certain extent protected from the shocks incident to ground unevenness. The old style of implement seat is in almost universal use and has the advantage that it is not affected by the weather. Some makers have provided cushioned seats. Owing to the habit of farmers of leaving their machinery in the open in rain or shine it is doubtful whether a permanently cushioned seat is advisable.

It would rather seem that a pressed steel seat so designed as to permit the use of a removable cushion would be preferable. Owing to the somewhat higher speed, and for other reasons, it seems desirable to make the sides and back of the seat somewhat higher than has been customary, so the driver may sit more securely therein.

Foot rests deserve more attention. If the driver must occupy an absolutely fixed position all day long it is very tiring. This is the case if only foot rests of shoe-sole form or stirrup form are provided. There is certainly a great advantage in having regular floorboards, so that the operator can change the position of his legs occasionally or can even stand up if he desired. These floorboards need be neither heavy nor expensive and they are certainly worth their cost.

The same as it pays to look after the health and comfort of industrial employees it will pay to take some of the rough edges off the tractor operator's life. In order to do the most work and the best kind of work the operator must enjoy bodily comforts.

Manufacturing Difficulties

CONCERNS which were fortunate enough to make as war products their own particular line of wares are in a much happier position to-day than those who had to go into lines that varied greatly from what they made in a commercial way.

The disruption of previous sources of supply is one of the chief difficulties. The uncertainty of the materials market is such that at the present practically everyone is waiting for breaks in prices which may or may not occur. The result is that buying is largely a hand-to-mouth proposition and long time material contracts are scarce.

This is not a good condition of affairs either for the manufacturer or the parts maker. The manufacturer is of course very wary of being caught with an unbalanced inventory and he is not going to contract for large supplies of anything as long as he is uncertain that other important parts may be late in arriving. The lesson of the cost of the unbalanced inventory has been too well learned.

It is agonizing to many manufacturers to see good labor slipping away from them when the war contracts are canceled simply because they are not able for various reasons to swing immediately over to peace production. This is particularly true in plants which are somewhat out of the way and where the labor has been gathered together for war work, but is now compelled to leave in search of other employment. These manufacturers know that in a few weeks they will be needing this labor badly and then it may be difficult to secure it.

Latest News of the

Measure to Regulate Aviation

Need for Temporary Measure Recognized—Licenses Under Secretary of Commerce

WASHINGTON, March 10—Although there has been no wholesale attempt to control or regulate future aviation in this country, or to formulate aerial laws as has been done in Great Britain by the Civil Aerial Transport Committee, there is a serious movement on foot looking toward future aerial regulations and development.

Officials in this country do not believe that the time is ripe for the formulation of complete permanent laws governing aviation. They point to the peace conference from which there may be issued an international law for aviation.

However, there is a general recognition of the need for some temporary regulations for flying and for the development of the aviation industry. Disappointment was expressed when the army appropriation bill provided for an air service of 1923 officers and 22,000 enlisted men, an organization which would only keep a maximum of 2000 airplanes in constant service.

The aviation industry in the United States, it is felt, should be encouraged as Great Britain is planning to encourage her aircraft manufacturing, by purchasing and using sufficient machines for the Navy and Army even though they are not immediately necessary and may be operated at a loss.

The Post Office also, it is said, should plan for a much wider immediate development of aerial mail so as to encourage the industry and keep it alive until it is a commercially profitable proposition. During the recent Congressional filibuster the army appropriation bill was "killed," and it is anticipated that the new bill which will be presented to the next Congress will call for a larger organization.

It is also planned to introduce at the next session of Congress a bill governing aerial navigation in the United States and its dependencies between the United States and foreign countries which will provide for the control of flying other than that for the Army, Navy and Marine Corps by the Department of Commerce, authorizing the Department of Commerce to license fliers and to publish and formulate rules and regulations for aerial navigation. The law provides for a report from the Secretary of Commerce to Congress no later than Dec. 10, 1919, of his action under this law and appropriates $25,000.

Original plans by the National Advisory Committee for Aeronautics, which has recognized the need for aerial navigation regulations, calls for a complete, comprehensive draft of law such as that of Civil Aerial Transportation Committee of Great Britain.

Toward this end the committee called a conference of representatives of the Departments of State, Treasury, War, Navy and Commerce. A subcommittee was appointed and an actual draft of aerial laws to be presented to Congress was drawn up. Under the plan it was intended to place all aviation under one head. Due to the fact that it would be difficult to assemble all air activities including those of the military and naval establishments under one civil head and also because the Peace Conference may completely alter present opinions regarding the air traffic, these plans were abandoned and it was decided instead to place the entire control of civil aerial transport under the Department of Commerce, leaving the army and navy independent.

Furthermore, it was decided that only temporary regulations should be devised, and the bill drawn up by the executive committee of the National Advisory Committee, headed by Dr. C. W. Walcott, chairman, and Dr. S. W. Stratton, secretary, therefore authorized the Secretary of Commerce "to make and publish all needful rules and regulations with the provision that he report his actions together with recommendations for further and more detailed legislation to Congress in December."

The proposed law was submitted to Secretaries Newton D. Baker, Josephus Daniels and William C. Redfield and approved by all three. The complete text follows:

"That no person, company or corporation within the jurisdiction of the United States and its dependencies, other than duly accredited officers and enlisted men of the Army, Navy and Marine Corps, shall use or operate any aircraft in aerial navigation from one State or Territory of the United States or the District of Columbia, to any other State or Territory of the United States or the District of Columbia, or from one place in a State or Territory or the District of Columbia to another place in the same State or Territory or the District of Columbia, or between the United States or its dependencies and any foreign country or any international waters, except under and in accordance with a license, revocable for cause, granted by the Secretary of Commerce upon application therefor; and the Secretary of Commerce is hereby authorized to grant such licenses and to make and publish all needful rules and regulations for the licensing and navigation of such aircraft; any violation of such rules or regulations to be punished by a fine not to exceed $500; and the Secretary of Commerce shall submit, by December 10, 1919, a report to Congress, giving in detail the action taken by him hereunder, together with his recommendations for further and more detailed legislation with respect to the navigation of aircraft and the licensing and regulation thereof. For the enforcement of this Act and the rules and regulations made in pursuance thereof, including personal services in the District of Columbia and in the field, the sum of $25,000 is hereby appropriated."

—

Gen. Mitchell to Head Air Service

WASHINGTON, March 11—Maj.-Gen. William L. Kenly, Director of Military Aeronautics, was relieved of that post to-day and in his permanent grade of colonel was ordered to report to the Chief of Field Artillery for duty. Brig.-Gen. William Mitchell, who has been in charge of the Flying Service of the American Expeditionary Forces, and who formerly had charge of the Flying Section of the Signal Corps, will be detailed to command the Army Aviation Service.

Ford Starts Plans for New Car

Edsel Ford Not to Resign—Dodge Brothers to Contest the New Venture

DETROIT, March 11—Henry Ford and his son Edsel returned to Detroit to-day, and the automobile manufacturer immediately started work on plans for his new car, which he hopes to sell at $250 or $300. How long he will continue this work is problematical for it is said attorneys representing the minority stockholders of the Ford Motor Co. are preparing to serve an injunction, halting further work and bringing the whole affair into court.

In newspaper interviews to-day Mr. Ford corroborates all statements made by himself or his son in Los Angeles and Kansas City relative to his new enterprise. He added a few more unpublished facts and discussed his proposed car in a more detailed way.

Edsel Ford will not resign as president of the Ford Motor Co. He will remain to protect the Ford interests. The Fords propose a factory organization five times that of the present Ford company, and when in full operation over 200,000 men will be on the new Ford pay-roll. One of the big plants will probably be located in Detroit.

Mr. Ford declares there will be a great and immediate demand for a car such as he proposes to build. It will embody everything necessary for a real family automobile. It will have all improvements and refinements that have been developed in recent motor car manufacture.

"The present Ford engine, Model T, was designed 12 years ago," said Mr. Ford. "Nothing of the old car will be used in the new manufacture. It will have an entirely new engine and new features. It will be just what the public wants. It is impossible for me to give you the exact details of the new car yet. Model T took 2 years and 4 months to perfect, so you see it may possibly take me a year before I have my new plan completely worked out."

Elliott G. Stevenson, of Stevenson, Carpenter, Butzel & Backus, attorneys for Dodge Brothers, declares neither Henry Ford nor his son Edsel will be allowed, without a legal fight, to withdraw from the Ford Motor Co. to manufacture a cheaper automobile for commercial purposes and which would antagonize present Ford interests. He says the Dodge brothers will contest the Ford withdrawal to the limit of the law.

"There would be no attempt to keep either Ford or his son in the firm if they desire to retire, but Henry Ford is under contract to

Automotive Industries

Government and Industries to Co-operate in Stabilizing Trade Conditions

Department of Commerce Industrial Board Will Function as Did Old War Industries Board But Without Definite Control—Reduce Basic Prices

WASHINGTON, March 10—That the Government will take a keen interest and supervisory attitude toward industry and will attempt to regulate prices of basic commodities is evidenced by the results of a meeting held here by the Industrial Board of the Department of Commerce, organization of which was told of in AUTOMOTIVE INDUSTRIES last week.

The board, which includes George N. Peak, formerly of the War Industries Board, and vice-president of Deere & Co., as chairman, comprises Samuel P. Bush, president of the Buck-Eye Steel Casting Co.; Anthony Caminetti, Commissioner of Immigration; Thomas J. Glenn, president of the Atlantic Steel Co.; George R. James, president of the Moore Drygoods Co., Memphis; T. C. Powell, Railroad Administration, and W. M. Ritter, president of the W. M. Ritter Lumber Co.

At the first meeting of the board it was generally agreed that although commercial stocks are depleted, money plentiful, building construction demanded, foreign trade prospects good, and the long period of forced economy relieved, yet the public is buying timidly and purchasing is decreasing in volume. Money is also timid and remains in the banks, construction of public and private works has not commenced, non-employment apparently is spreading and few factories are running full.

The first concrete step to alleviate these conditions will be a conference here Wednesday of a committee of steel and iron men with the board, at which it is planned to reach an agreement on lower prices for iron and steel to relieve the present business stagnation.

The cause for these conditions, it was decided, lies in the abnormal and abortive increased production of special war commodities, with the consequent increase of prices, leaving a highly inflated and irregular market far above what the peace demands will support.

The normal operation of the law of supply and demand, it was said, did not cause this condition, and consequently cannot cure it, and with the realization that some prices must fall there is little purchasing until they do fall, and we have as a result an unstable and dangerous market condition. Some of the uncertainty, it was decided, results from the Governmental accumulation of raw, finished and partly finished material which must be fed very carefully into the market.

The remedy, it was agreed, lies in curing the condition as it was caused. It was caused by the co-operation of the industry with the Government in the war and can be cured by the co-operation of the industry with the Government during these present peace times.

To this end the Industrial Board plans to operate as did the War Industries Board, but without the definite control which that board exercised. The Industrial Board plans a general co-operation with all industries, first, by reducing the basic commodities such as steel, to a stable basis.

The industries affected will be invited into conferences for the purpose of bringing prices of basic commodities to a normal level. It is expected that this will automatically reduce the price of fabricated articles. If it does not so operate in any instance the industry affected will be invited into conference.

It is expected that industry will agree to the policy of the board, which is that the cost of living must be substantially reduced before labor should be asked to accept lower wages. This of course must mean that industry must stand the first shock of readjustment.

In discussing this problem and this plan of fixing prices co-operatively, objections to the plan were noted and debated. It was decided that business resentment of Government interference and control could not be regarded as an argument against the plan inasmuch as the Government co-operated helpfully with industry during the war. What is proposed in this new plan is not Governmental control. The board has no power of control and plans only to provide a forum in which industry can meet and agree on a policy for this at Government instance and with the approval of Government.

The board also expects to solve the problem of redistribution and readjustment of labor by stimulating peace industries through the price-fixing plan.

That many of the industries will have to take a loss on products purchased at war prices if there is a general reduction in selling prices it was agreed is true whether the proposed plan is attempted or not, but at least it is expected that buying will begin again and the continued business will overcome the overhead which would be vastly greater if the present period of stagnation continues.

The activities of the Industrial Board will only be temporary and will endure until the gap between war and peace is closed, when a law of supply and demand will again be allowed to operate normally. The offices of the board will be located in the Council of National Defense Building, Washington.

—

TO MAINTAIN 22 FIELDS FOR AIRCRAFT

WASHINGTON, March 13—The War Department has arranged to maintain twelve temporary flying fields, which will be used for storage purposes, four permanent balloon fields and four permanent training fields, and at least two experimental fields.

The first intention to retain only two training fields was abandoned when this number was found insufficient, and in consequence Arlington Field, Houston, Tex.; Post Field, Ft. Sill, Okla.; Kelly Field, San Antonio; Rockwell Field, San Diego, Cal.; have been chosen as the permanent training fields.

The twelve fields to be maintained for storage purposes have not yet been definitely named. The War Department believes it can store its hundreds of elementary and advanced training planes for a period of years without deterioration. Langley Field will be retained as one of the experimental fields; McCook Field will be given up, as the city of Dayton wants this property back. Wilbur Wright Field, which has been suggested as an experimental field, will not be used, because of the possibility of floods.

The Air Service would like to purchase the Dayton-Wright plant and use it for its main experimental depot. The Dayton-Wright equipment includes an excellent experimental field and a number of structures, including buildings as large as 1000 x 300 ft., and is considered by the Air Service as especially suitable for experimental work. If this plant can be purchased the Air Service will move its present repairshop from Indianapolis to Dayton. The Government already has a large financial interest in Dayton-Wright, due to war financing, and the balance of the purchase price would consequently be insignificant. In the event that the purchase of the Dayton-Wright plant cannot be consummated some other site in the Middle West close to the airplane and engine factories will be selected.

—

May Sell Army Trucks

WASHINGTON, March 12—In view of the decreased size of the Motor Transport Corps and the entire army, as provided for by proposed legislation, it is now considered possible that a large number of war trucks may be sold. The National Automobile Chamber of Commerce has already informed the War Department that it desires first knowledge of any proposed sales and the opportunity to work out some scheme whereby the manufacturer will be protected. The Motors Vehicle section of the Army has assured the N. A. C. C. that it will co-operate with the industry.

—

No Plans to Sell Planes as Junk

WASHINGTON, March 12—The War Department denies knowledge of any plan to sell any airplanes as junk, in refutation of newspaper dispatches published this week to the effect that army airplanes would be sold at ridiculously low prices.

Will Pay Promptly on Contracts

Additional Regulations Promulgated to Speed Liquidation of All War Debts

WASHINGTON, March 11 — Additional regulations for the payment and adjustment of war contracts have been compiled by the Assistant Secretary of War, Benedict Crowell. They include provisions for the payment of all proper items of expense to contractors without awaiting full settlements of contracts provided they can be properly vouchered as items of cost. Provision is also made to expedite payments under termination clauses where contractors waive rights to proceed with further production and accept the notification of the termination of the contract. Where this is done it is not necessary to await final determination of the total amount of the payment due the contractor, but instead, payments can be made as rapidly as determination for raw material, commitments to sub-contractors, etc.

The provision allowing partial payment of 75 per cent of the contracts as determined by the War Department is included, and Claim Boards are authorized to make these payments when it expedites settlements of outstanding contracts.

In every instance where a prime contractor has to negotiate the settlement of a sub-contractor the local Claims Boards are urged to be prompt in determining what basis of settlement it will approve.

An interpretation of a recent circular, No. 111, with regard to compensation for capital tied up in raw material, decided that so far as the contractors have properly made expenditures and incurred obligations in the performance of contracts the War Department should provide for reimbursement of such expenditures with a reasonable remuneration for the use of capital and service of the contractor, making an allowance up to 10 per cent on the cost of the articles in process, and in addition, in the case of cost plus contracts an extra compensation estimated at the rate of 6 per cent per annum of the capital tied up in raw materials should be allowed, or if the capital tied up in raw materials was borrowed the contractor is to be allowed the rate of interest which he pays for it, provided that this is not already carried in other charges by the contractor.

—

Sales Control Board for Surplus Supply Settlements

WASHINGTON, March 11—A Superior Board of Sales Control has been organized, comprising the Director of Sales and the Chief Sales Officer of each sales organization under the various bureaus of the War Department. This board will consider all problems affecting the sale of war surplus supplies, and will formulate the policies and principles covering these sales. It will be the highest body in charge of sales under the Director of Sales, and will have under it Local Boards of Sales Control organized in each supply bureau and department which will form the administrative bodies.

These boards will comprise the heads of the particular sales organizations in each supply bureau and such other members as the Chief of the Bureau will select. Special material boards may be organized when necessary to handle the sale of certain specified materials in each department.

—

No Army Vehicles Have Been Sold in France

PARIS, Feb. 22—No American Army automobiles have been sold in France, and no decision has been taken regarding disposal of army automobiles now with the Expeditionary Forces, according to a statement made by Gen. M. L. Walker, director of the Motor Transport Corps in France.

This definite statement puts an end to the wild rumors which have been circulating in France for the last few weeks to the effect that the American government had insisted on the French absorbing all the motor vehicles owned by the American forces in France. Assuming, without any foundation whatsoever, that France had to absorb the 80,000 American army trucks, many newspapers have been crying scandal and have endeavored to stir up trade animosity.

—

Parsons Enlarges Its Plant

DETROIT, March 11—The Parsons Mfg. Co. has purchased an adjacent building having floor space of 30,000 ft. Another addition is under construction and will be completed shortly.

—

Clayden Leaves Wright-Martin—To Open English Office

NEW YORK, March 12—A. Ludlow Clayden has resigned as consulting engineer for the Wright-Martin Aircraft Co., a position he has held since the winter of 1917. He will establish a consulting engineering business in London early this summer, and will specialize on the investigation of European propositions for American manufacturers. He believes that as soon as tariff questions have been settled connections between America and the allied countries of Europe will be much closer than before the war, and plans to spend a large part of his time in this country.

Clayden spent most of 1918 in Europe studying the methods of manufacture of the Hispano-Suiza engine and its applications to allied airplanes. Previously he was engineering editor of AUTOMOTIVE INDUSTRIES for 3 years and chairman of the Standards Committee of the S. A. E. from 1915 to 1916. He plans to sail for England in about 60 days.

Sell Surplus Aircraft Material

Materials Disposal Section Formed—Machinery to Be Sold at Appraised Price

WASHINGTON, March 10—There has been formed a Material Disposal Section of the Bureau of Aircraft Production, organized on a basis similar to that followed by large commercial houses which handle sales through branch offices. This section will be under the direction of 1st Lt. Charles S. Shotwell. Sales will be made under the supervision of a sales manager stationed at Washington.

The Bureau of Aircraft Production will probably have for sale the following classes of material, and as soon as this material has been established as surplus and policy for the sale of same determined, the bureau will issue bulletins covering the material for sale.

Machine tools and fixtures.
Electrical machinery.
Dies, tools, jigs and gauges.
Chemicals, paints and oils.
Metals.
Motor Accessories.
Lumber.
Hardware.
Buildings and Lands.
Fabrics.
Scrap.
Shop equipment.
Office equipment.
Miscellaneous.

Sales negotiations will be handled by salesmen in each of eight district branches, to be located in Boston, Buffalo, Chicago, Dayton, Detroit, New York, Pittsburgh and San Francisco. These salesmen will be authorized to make sales of property wherever located, after the same has been cleared by the Board of Sales Review of the Office of the Director of Sales, so that the prospective buyers will communicate with the branch office in the city located nearest them.

This arrangement, it is expected, will make it possible for manufacturers needing machinery and supplies to purchase conveniently and at fair prices. The salesmen will have full authority to sell at the best offer made, provided that offer is at or above an appraised value arrived at independently, or at market value in the case of raw material.

—

Piehl Elected President of Chicago Automobile Association

CHICAGO, March 11—L. A. Piehl, Mitchell dealer, was elected president of the Chicago Automobile Trade Association at its fifteenth annual meeting. Other officers elected were: Secretary, R. C. Cook, Fiat dealer; treasurer, Thomas H. Hay, Chandler dealer. The new directors are: G. R. Dashiell, Dodge dealer; H. P. Branstetter, Kissel, and Charles Gambill, Marmon.

The result of the show held here by the association was $15,000 profits after rebating to the dealers 75 per cent of the cost of their space.

England Lets Down Bars Against Canadian Products

Will Permit Imports of Products Manufactured Entirely Within Domains of British Empire—Action Will Stimulate Canadian Manufacture

NEW YORK, March 13—Although it is reported from Washington that England has modified her restrictions to the extent of allowing imports from British colonies, official confirmation of the report has not been made nor has the Department of Foreign and Domestic Commerce any information on the subject. It is reported from Ottawa, however that the embargo on imports has been lifted insofar as British colonies are concerned.

Ottawa Confirms Report

DETROIT, March 13—A cable to the Trade Commission in Ottawa confirms and supplements a report published that the British Board of Trade has announced a definite removal of all restrictions of imports into Great Britain which come from within the British Empire. The Canadian mission in London further states that the Trade Board regulations will insist that goods of only British Empire origin shall be exempt from the rigid general restrictions which were imposed in continuation of wartime trade regulations. Canadian manufacturers should comprehend the importance of the fact that foreign goods cannot, therefore, reach England by way of Canada.

Willys-Overland and other big manufacturers declare that Great Britain cannot possibly manufacture enough cars to supply the British demand, and that within the next month or two the embargo against American made cars will be lifted. They are sitting tight waiting for further action on the part of Great Britain.

Would Encourage Canadian Manufacturers

DETROIT, March 12—The lifting of the embargo by England, which is now accepting imports from her colonies, will have a tendency to promote complete manufacture of American automobiles in Canada. This is the belief of several Detroit manufacturers operating Canadian plants.

Whether this will give Detroit makers a clear pathway into England through the Canadian branches is problematical, but it is certain that few would take advantage of such subterfuge to gain a European market. The ultimate tendency, they declare, will be enlargement of Canadian assembly plants into Canadian manufacturing plants turning out cars complete.

The Canadian Ford company will not be affected. This company will have its hands full caring for Canadian territory, while the Manchester plant will look after British and European business. The Manchester plant is now running 300 cars weekly, but is not making all of its parts as yet.

No Australian Embargo

NEW YORK, March 13—The report to the effect that Australia had declared an embargo against all commodities not of British origin is not entirely in accordance with facts. Cable dispatches from Melbourne state that some confusion has arisen and that the embargo is intended to cover only dyestuffs.

Preliminary Tax Interpretations

NEW YORK, March 12—Although no formal written interpretations of the new war revenue bill have been made, the National Automobile Chamber of Commerce has had a number of lengthy conferences with the officials of the Revenue Bureau on all phases of the new act. In consequence, formal written rulings by the bureau are promised for the immediate future.

In the meantime, and in consequence of these conferences, the N. A. C. C. is pointing out to its members that it seems likely that certain sections of the law will be interpreted about as follows:

All exports of automobiles, and tires, inner tubes, parts and accessories will be exempt from the tax, no matter whether the export is made direct by the factory or through any number of intermediaries. This export exemption is therefore broader than under the old law. All that is necessary is for the manufacturer when he makes the sale, to be able to determine that the sale is for export and that in due course the article is eventually exported.

The Commissioner will shortly issue regulations as to how the intent to export shall be shown. Meanwhile bills of lading and other papers involved in the transaction should clearly show that the shipments are intended for export.

Shipments to the Philippine Islands, the Virgin Islands and Porto Rico are considered export shipments, but the Panama Canal Zone, Alaska and Hawaii are considered part of the United States.

Sales of automobiles, tires, inner tubes, parts and accessories to the Federal Government, to a state or political subdivision thereof will continue to be tax free under the new law, and it will not be necessary to first obtain certain written documents from the buyer. The statement of the manufacturer that the car is sold to the exempt party will be sufficient.

Under the new law the taxpayer who sells both at wholesale and retail may estimate the tax on the retail sales on his customary wholesale price, the customary wholesale price being his highest usual wholesale price, or the wholesale price bearing the least discount.

While there is no floor tax under the new law, manufacturers of automobiles, tires, inner tubes, parts and accessories who have on hand such articles made before Feb. 25, 1919, will be subject to the tax when they sell these articles.

Under the new law no self-propelled fire extinguishing apparatus will be considered a taxable vehicle. This is a broadening of the old law under which certain particular types of fire extinguishing apparatus were considered taxable automobiles.

As the new law contains a penal section (1319) making it a misdemeanor to misrepresent to the purchaser the amount passed on and alleged to be the tax, it is extremely unsafe for taxpayers to use the so-called average tax method.

The most troublesome provision of the new law is the tax on tires, inner tubes, parts and accessories. The Revenue Bureau is having considerable difficulty in getting an exact and workable definition of parts and accessories. It will probably rule that substantially complete manufactured articles of commerce which form parts or components of a complete automobile or which are attached to or used with an automobile are taxable parts and accessories, provided they are primarily intended for such use. This would mean that sheet metal, lumber, leather, wire and the like would be considered 'material' and not taxable. Also that incompletely manufactured articles such as forgings for crank shafts, blanks for gears, and the like would not be taxable. Likewise completely manufactured articles such as ordinary bolts, rivets, screw drivers, wrenches and the like would not be taxable because they are not primarily intended for the automobile but have many other uses.

Spark plugs would probably be considered as primarily intended for automobiles and therefore taxable. The ruling on ball bearings is debatable.

Whatever may be the proper definition of parts and accessories another troublesome point is that sales of such parts and accessories as well as tires and inner tubes to automobile manufacturers are exempt from tax. The Revenue Bureau will probably rule that the sale of such articles by their makers to automobile manufacturers who intend to embody them in their product will be tax exempt, but that any excess purchased for the purpose of replacing defective parts or of selling to car users to replace articles worn out in use would be subject to the tax, with the right of the taxpayer to obtain a refund or credit of taxes if it can be demonstrated that the articles were either given in replacement or were embodied in the complete automobiles by the factory. Parts or accessories which are usually charged for pending settlement of the question as to whether they should be free replacement parts are tax free, but of course are treated as a taxable sale if, and when it is found that the returned part is not defective. It is advisable to make shipment of such replacement parts on memorandum.

In other words, the Bureau is inclined to consider that the factory when it makes the cars is operating as an automobile manufacturer, but when it sells repair parts it is not, and therefore the sale for this latter purpose is not exempt from the tax. This is considered highly unsatisfactory and steps are being taken to obtain a more practicable ruling.

Meachams Organize Gear Corp.

SYRACUSE, March 12—The Meacham Gear Corp. has been organized to take over the New Process Gear Corp., the manufacture of rawhide pinions by the process developed under the Meachams' direction. Officers of the new corporation are: President, T. G. Meacham; vice-president, T. W. Meacham; treasurer, J. F. S. Meacham. It is incorporated for $300,000 and has purchased a 3-story building at 411-415 Canal Street. George W. Wood, who is secretary, will act as superintendent, and H. W. Kiddle as assistant superintendent.

New Dodge Four-Door Sedan

NEW YORK, March 11—Dodge Brothers dealers are expecting deliveries within the next two weeks of a new four-door sedan which will sell for $100 more than the present two-door model, making the price of the new model $1,876. The chassis will be the same as at present.

New Device to Measure Gas Consumption

ST. JOSEPH, MICH., March 11—The "Silent Guard," a new device for measuring gasoline consumption and tire mileage, is being manufactured by the Upton Machine Works. The Silent Guard Co. opened offices in the Owen building.

Flint Facing an Era of Prosperity

Community Has No Unemployed—Big Production Plans Under Way—Wages High

FLINT, March 7—The last traces of war are being removed from Flint industries. The automotive plants here are winding up their war contracts, and the last government cars, motor trucks, trailers, etc., are already complete or are now leaving the assembly line. The city has withstood the shock of from-war-to-peace reconstruction well, weathering this trying period without a suspension of business or suffering a serious labor surplus. Few automotive cities have recovered so quickly the normal tenor of industrial activity. Few cities are to-day facing a brighter business future than Flint.

The armistice in November found Flint working over-time on war work. Buick, Dort and Chevrolet were bending all efforts to the production of war vehicles. Labor was at a premium. Wages were touching high marks theretofore unknown. The cost of living was climbing correspondingly. More men were being employed than ever before. Marvel Carburetor and Champion Ignition were rushing work on carbureters and spark plugs for war machines and aircraft engines. Flint was up to its neck, so to speak, in war activity, and most of its manufacturing plants were hitting the 100 per cent war production basis requested by the Government. Others were rapidly approaching this mark.

Plants Continued Operation

Flint met its reconstruction problem squarely. Its big automobile plants, in the face of canceled or greatly reduced contracts, continued operation. The men stayed on their jobs. One or two departments closed up for a few days, but comparatively few men were out of work. War work was cast aside. Everything depended on the rapidity with which the plants could get back into commercial production. For five days Dort produced no war or peace vehicles, but every man was employed at inventory work. Although conditions merited laying off at least 4000 of the 13,000 Buick employees, President Walter Chrysler kept every man on the job at the regular war-wage basis.

Flint reconstruction and just how the big men of the city met and solved their many serious problems is a story in itself. They not only cared for their laboring men but they launched an assault on the high cost of living which resulted in a cut of 15 per cent in the price of rent, clothing, eatables and other necessaries of life.

To-day, not quite four months from the day the armistice was signed, finds Flint factories back at normal. Buick is making 400 cars a day and is daily increasing the number of men employed and its production. Dort is making 65 cars daily, which is 15 cars more than it ever made before. The W. A. Paterson Co., which practically did nothing during the year of the war, has resumed normal work, giving employment to 150 men, who are turning out 20 machines a week. Flint Varnish Works, Imperial Wheel Co., Champion Ignition Co. and Marvel Carburetor are rushed with work, and their respective sales departments are flooded with new orders.

There is no question but what this city is facing a great future. It is practically a General Motors town, and the General Motors Corp. is planning a great period of expansion during the next two years. The Buick Motor Car Co. can see nothing ahead but prosperity. President Walter Chrysler publicly states that his concern will be making 1000 cars daily in 1921, doubling its present manufacturing facilities and the number of men employed.

New Plants Building

The Buick company has added several new building units. Rumor has it that Chevrolet will soon be housed in a new factory plant, and the Dort Motor Car Co. has purchased a site on the east side of Flint and is preparing to build, it is unofficially said. The Marvel Carburator Co. will be in a new factory building this year, which will permit this company to double production. The Champion Ignition Co. is now using the buildings erected for war work, but is in great need of further expansion. If this company's business continues to increase more buildings must be built, an official of the company said.

Organized labor is getting firmly established in Flint. This has always been a nine-hour town, but many of the factories are now coming down to an eight-hour schedule. The Buick company and most of its subsidiary organizations are now on an eight-hour basis. The Dort company was the first concern to adopt eight hours as a working day. Chevrolet is still running on a nine-hour schedule, however.

Unemployed from Detroit

Employment men declare that the slight labor surplus recently experienced was not due so much to Flint industrial concerns laying off men as it was due to an influx of unemployed from Detroit and other neighboring cities, where the complete suspension of many big plants threw thousands of men out of employment. Scores of these men found work here. Nearly every returned soldier, whether a former employee of a Flint plant or not, was placed at work by the various Flint companies.

Flint's great fear now is a labor shortage. With her largest industries planning huge expansion, the demand for labor is bound to become pronounced in the course of a few months. The city is already facing a serious housing situation. Hundreds of small homes have been built, but hundreds more of them must be erected at once if the city is to keep pace with her growing manufacturing interests.

The Buick company is still paying its men according to the scale in force during war days. Men working on a regular hour rate are enjoying the same rate. Workers whose efforts were compensated on a piece-work basis are of course not making as much as formerly, inasmuch as all war work is practically at an end. Piece workers are now averaging from $5.50 to $8 a day here and in the other factories. There is but little difference in the wage scales of the various plants. The average rate per hour for common labor in Flint is 46½ cents. In 1918, just prior to the entrance of the United States into the war, the average rate was 30 cents.

The future will bring a wage increase, rather than a decrease, employment officials unanimously declare. Flint will be in need of men shortly and there is likely to be a scramble for available labor. The manufacturers must offer an inducement to bring labor to the city, and this fact in itself will keep the present wage scale up, if not actually increasing it materially.

Trailer Makers to Meet in Detroit

CLEVELAND, March 10—Plans started at Cincinnati and rehearsed here recently to give trailer manufacturers a bigger place on the world's industrial map than they have had will be completed at a meeting of trailer manufacturers in Detroit March 18.

The gathering will be held under the auspices of the Trailer Manufacturers' Association of America, and the prime object will be the announcement of a program that will keep alive the trailer enthusiasm and prospects that the efficiency shown by the trailer in the war engendered.

The trailer manufacturers started an organization two years ago, but interest waned. The body was revived at Cincinnati on Feb. 20, when the association was reorganized and given the name Trailer Manufacturers' Association of America. The Executive Committee met here Feb. 28, considered plans for strengthening the organization, as well as for promoting the manufacturers' interests, and then adjourned after leaving the questions open for a general meeting in Detroit.

W. E. Ferris, secretary-treasurer of the Ohio Trailer Co., Cleveland, is president; J. C. Endebrock, of the Trailmobile Co., Cincinnati, is secretary-treasurer. These men, with W. A. Murfey, of the King Trailer Co., Ann Arbor, first vice-president; R. C. Sykes, Troy Wagon Works Co., Troy, Ohio, second vice-president; W. R. Bonds, of the Detroit Trailer Co., Detroit; W. F. Jolley, of the Miami Trailer Co., Troy, Ohio, and C. H. Martin, of the Martin Rocking Fifth Wheel Co., Springfield, Mass., compose the Executive Committee of the association.

Federal Highway Plan Endorsed

200 Acceptances to Council Received—Demand Federal Control of Roads

WASHINGTON, March 8—More than 220 acceptances have been received by the Highway Industries Association for membership to the new Federal Highway Council which the association is forming, and which will include those men most prominently identified with the industries interested in roads of the Nation. The council, formation of which was announced in a recent issue of AUTOMOTIVE INDUSTRIES, will work as a unit for the mobilization of Federal resources and control for highway construction, and for the crystallization of public opinion for three projects approved at the Chicago Highway Congress last December when resolutions called for—

Highway Congress Resolutions

1. Creation of a Federal highway commission to control highway construction and development.
2. Federal financial aid for State highway construction.
3. All governmental control of highways to be under the Federal highway commission.

The late appropriation of $200,000,000 for highways provided by the new Post Office bill completes in part the demands of section 2. These funds will be devoted largely to aiding the states, which in recent years voted road funds, but because of the increased cost of labor and materials were unable to apply the funds provided which called for a specified number of miles of construction. With the additional money from the Federal Government this difficulty will be overcome.

The creation of a Federal highway commission is well started by the recent introduction of a bill by Senator Townsend, which will probably come up at the next session of Congress and which was introduced at this time to allow for public consideration and discussion.

Government Control of Highways Urged

Government control of highways entirely under the Federal Highway Commission as demanded at the Chicago meeting has not yet been discussed in Washington. This matter, though entirely logical and feasible according to highways authorities, may meet with some difficulty from the reluctancy of Government departments to give up any work already under their supervision. The roads are now under the Department of Agriculture, and it yet remains to be seen if this department will recognize the fact that roads are now so important that they deserve a separate department that can be devoted to highways work only.

That the nation is recognizing the need and value of good roads is apparent in the national and state interest now displayed, and in the co-operation extended by industrial organizations that have no direct interest in the work, but which understand that highways mean a more prosperous and healthy condition generally. For example, more than 600 organizations, including silk manufacturers, paper box makers and automatic sprinkler producers, have endorsed the resolutions approved at the Chicago highways meeting, besides every good roads organization.

All Industries Profit by Good Roads

The association headed by S. M. Williams has been an important factor in securing the recent state and Federal appropriations. It has worked without attempting to conceal the direct relation of its interests with the industries that will profit through good roads. It has openly announced these interests, contrary to the usual custom that many like bodies adopt. But, according to Mr. Williams, the policy is based on the fact that the industries represented should and do know more about road building than any other interests, and though their interest may be more or less personal, the results that will accrue through road development more than justify the stimulating causes. Industries, it was stated, have a legitimate right to appeal to legislatures despite selfish interests, when the results make for the public good.

—

Bill for Regulation of Railroads Introduced

WASHINGTON, March 7—A bill was introduced in the Senate Tuesday for the return and regulation of the railroads. The plan was prepared by the National Association of Owners of Railroad Securities, and has had the attention of the Senate Committee on Interstate Commerce. In presenting the bill attention was called to the fact that it represents largely the interests of the millions of people holding the outstanding securities of the railroads. The fundamentals include:

A definite rule for rate-making, producing a fixed reasonable return to the railroads; provision whereby excess earnings over and above the said fixed reasonable percentage return go into a fund to be expended in the public interest; regional commissions established in the six rate-making districts into which the country is divided by the Interstate Commerce Commission; the incorporation of the National Railways Association to assist in the return of the railroads to their owners, providing means therefor to continue, inaugurate and put into effect such plans of unification, joint use of railroad terminals and other facilities as in the judgment of the trustees thereof may be expedient and in the public interest. There are to be 18 trustees of this corporation, 9 to be the present Interstate Commerce Commissioners, and 9 to be representatives of the railroads, from various sections of the country.

February Production Doubles January

Factories Nearing Normal Output—Labor Situation Cleared Up

DETROIT, March 8—Passenger car production in Michigan and Ohio during February was double that of the preceding month. This is shown in the production reports from 37 leading automobile manufacturers. These plants produced 4871 cars daily in the month, as compared with 2833 in January. Nearly every big company is nearing normal production, and the last of March will find them all back at their regular peacetime stride or setting new production records.

The labor situation has practically cleared up. It is estimated that Detroit's labor surplus has dwindled to 20,000 men. Discounting a normal floating labor surplus of 15,000, this leaves approximately 5000 Detroiters, willing to work, who are unemployed.

The materials situation is improving rapidly. Parts makers are getting back into full production and are now able to meet demands. Every company with the exception of Packard is in production. The Packard company has started work on its new passenger cars, and the first of these will leave the assembly line some time in April.

Daily production figures for January and February follow:

Car	Jan.	Feb.

1917 Tons of Rubber From Canada to United States

WASHINGTON, March 7—Following the removal of restrictions, 1917 tons of rubber were released for entry from Canada to the United States on Feb. 13, 1919, according to an announcement made by the War Trade Board.

Feb. Rubber Imports Double Jan.

14,079 Tons Set High Water Mark for Same Month in Last Four Years

NEW YORK, March 12—In the past four years the February importation of crude rubber never reached the volume of 14,079 tons brought into the United States last month. Although February is not usually as heavy a buying month as the later spring and summer, this year's record is higher than that for April any preceding year. Last month's figure is 971 tons more than February, 1918, and almost double 7,235 tons for January, 1919.

Figures compiled by the Rubber Association of America for importation records of crude rubber for the past four years follow:

	1916 Tons	1917 Tons	1918 Tons	1919 Tons
January	9,162	12,788	16,084	7,235
February	1,597	10,162	13,108	14,079

Class Automobiles as Unmarketable Staple

WASHINGTON, March 12—The Federal Reserve Board has classified passenger automobiles as "not marketable staples," and as a result many rediscounts on dealers' notes are being refused by Federal Reserve banks. In the case where the dealer is discounting his notes directly with the Federal Reserve banks there appears to be no objection on the part of the Federal Reserve Board. But they refuse to approve or allow rediscounts where the note is passed through other hands, beginning with the note broker.

There is no clue available as to the reason for this classification of passenger cars. Alfred Reeves, general manager of the N. A. C. C., is in Washington and has conferred with the Federal Reserve Board commissioners. Reeves will file complete data on the subject with the board shortly.

Saxon to Occupy New Factory

DETROIT, March 11—The concrete and steel plant built for the Saxon Motor Car Corp. will soon be ready for occupancy. Just as it was near completion, war started and the government, looking for warehouses big enough to house its ordnance supplies, took over the new plant for the duration of hostilities. As the government is now able to divert its war materials for civilian uses the Saxon plant will soon be emptied.

Weekes-Hoffman to Make Gears

SYRACUSE, N. Y., March 4—The Weekes-Hoffman Co. has completed plans to enter the gear manufacturing industry. It will shortly be turning out gears for automobiles and tractors in quantities which will necessitate the employment of 250 men in the plant on Dickerson Street. W. H. Diefendorf has resigned as chief engineer and a director of the New Process Gear Corp to join Weekes-Hoffman Co. as vice-president and general manager. J. M. Weekes is president and A. J. Hoffman secretary and treasurer.

French Mfrs. Arrange for Purchase and Manufacture in U. S.

NEW YORK, March 10—Emmanuel Pironneau, a French engineer, has opened a New York office at 1779 Broadway and is representing a number of French manufacturing concerns, for whom he will purchase machine tools and supplies, and will also arrange for the manufacture in this country of a number of French car accessories. The manufacturers of the "Solex" Carbureter and Radiator have authorized Mr. Pironneau to arrange for their manufacture in this country.

Sun Carbureter Taken Over by J. B. D. Carbureter

MILWAUKEE, March 11—The Sun Carbueretor Co., organized with a capital stock of $100,000, has taken over and will develop the business established several years ago by the J. B. D. Carbureter Co., Milwaukee. J. B. Drahonovsky, designer of the carbureter which the new company will manufacture, will be general manager. A new plant will be erected with a capacity of 1000 carbureters a day. At present the company owns a small machineshop and experimental plant on the Howell Road. F. J. Ramler, head of the Curtis Rubber Co., Milwaukee, and Emil F. Deuster are interested in it.

					$82,557,557.50

WASHINGTON, March 10—Motor vehicles valued at $82,557,557.50 are still under contract to be built for the United States Army, according to figures given out in the hearings before the Committee on Military Affairs for the Army Appropriation Bill, 1920. Eighty million, eight hundred and nineteen thousand, seven hundred and ninety-eight dollars and fifty cents covers the manufacture of 28,739 trucks and 1884 ambulances; $39,984 is set aside for twelve touring cars, and $1,697,775 is included in the contracts for motorcycle requirements.

WASHINGTON, March 8—United States army contract cancellations, affecting 76,205 trucks, 18,507 passenger cars and 32,000 motorcyles, are announced as a result of the hearings of the Committee on Military Affairs for the appropriations for 1920. According to the report, 100,683 trucks, 19,060 passenger cars and 39,000 motorcycles were contracted for.

The list of cancellations also includes the following:

Article	Quantity Ordered	Quantity Cancelled
Bodies	56,645	37,440
Differentials	5,000	5,000
Engines	2,500	2,500
Frames	27,250	25,500
Axles	36,524	35 980
Transmissions	27,500	27,500
Tires	15,000	15,000
Tires, solid	7,578	7,578
Trailers and Tanks	10 301	7,451

In addition to this list there were 25,000 each contracted for and totally cancelled of the following: clutches, universal joints, radiators, steering gears, and springs.

Swedish War Tire Prices to $500

Shortage of Tires and Gasoline—75 Per Cent of Cars Unable to Operate

NEW YORK, March 10—Some of the difficulties that Sweden had to put up with before armistice date have been told in America by Capt. John Neren, editor of Motor, a monthly published in Stockholm. Captain Neren says that during the war 34 x 4 and 35 x 6 tires sold as high as $225 and in some cases up to $500 each. Tires were regularly smuggled from Russia through Finland into Sweden. There was never a time during the war when there was a surplus of more than 5000 tires on hand for the entire country.

Required Permit to Operate Car

It was difficult to operate an automobile as it was necessary to first secure permission to use the car. It was then necessary to get permission to purchase gasoline, which sold as high as $2 per gallon. This aroused the opposition of the people and was perhaps the greatest bar to the general use of automobiles. Sweden has to-day between 6000 and 7000 automobiles and approximately 75 per cent of these were idle during the war.

Since the armistice, tires and gasoline have been arriving in Sweden so that motoring conditions are rapidly opening up. In January, over 2000 tires arrived from the United States, and upward of 1,000,000 gallons of gasoline. Motor trucks are at present on steamboats headed for Sweden.

Alcohol Successful Fuel

During the war the development of alcohol as a motor fuel made considerable progress and engines were developed in which either alcohol or gasoline could be used, the compression being doubled by some device when alcohol had to be used. Sweden has taken up the manufacture of alcohol at a production of 125,000 gallons per month. Captain Neren believes that Sweden can manufacture 5,000,000 gallons per year, which would be sufficient for all of the motor cars and motorcycles there. The price during the war was $1.50 per gallon of 4½ litres. (One litre equals .26417 of a United States liquid gallon.)

Automobile manufacture in Sweden is confined to two factories with a total production of 500 cars and a possible capacity of 1000. There are in addition two truck companies that have an annual production of 100.

There has recently been developed in Sweden a new device for feeding gasoline from the tank to the carbureter which can be used on all types of four-cycle engines, and which has already been patented in America. During the war, when alcohol was being largely used for fuel, ether was used for starting purposes.

N. A. C. C. Will Hold Shows in 1920

NEW YORK, March 12—One of the most important matters decided at last week's meeting of the N. A. C. C. was that the chamber should hold the New York and Chicago shows in 1920. The truck making members also voted in favor of truck shows, provided it is possible to hold them at the same time as the passenger car shows.

Dealers in these cities had hoped that they might be permitted to repeat their present year's program and stage the shows with the approval and co-operation of the factories, but no support for this idea was evident at the meeting despite the fact that a big percentage of the chamber's membership had unofficially gone on record in favor of the dealers.

The statement issued regarding the meeting stated that "the question of closer co-operation by and with the (New York and Chicago) dealers' associations was discussed" and "the directors probably will act upon this suggestion at their April meeting." This statement was taken to mean that the N. A. C. C. would consider giving both associations a larger share in the show profits than they have heretofore received.

The Chamber also resolved that the Bolsheviki movement is being aided by an undue amount of newspaper publicity and that the "best interests of general business and the entire nation demand that such articles should be removed from front page prominence where their real news value precludes excluding them entirely from the columns of public print."

Trade reports indicate that the factories are fast coming back into production, carload shipments for February being approximately 19,000, whereas in February, 1918, they were 12,030.

Post-War European Models Not Due Yet

CHICAGO, March 6—Passenger cars are beginning to be built in Europe for the general market, but real post-war models will not appear for many months, is a message brought back by David Beecroft, directing editor of the Class Journal Co., who has just returned from a tour of the automotive factories of France, England and Italy. Mr. Beecroft, in an address to the midwest section of the Society of Automotive Engineers last night, said that significant developments in the after-the-war designs are commencing to appear.

To Form Welding Association

NEW YORK, March 12—A meeting has been called for Friday, March 28, at the Engineering Societies' Building, New York, to form the American Welding Society, which will be a merger of the Welding Committee of the Emergency Fleet Corporation and the National Welding Council. It is the purpose of the society to become a disinterested and dependable source of information on welding, not only for the benefit of manufacturers of welding apparatus and supplies, but also to aid those who use welding processes in their production and those who purchase welded goods. A temporary organization already has been formed, and it is the plan of the permanent body, which it is hoped will come into being on March 28, to provide for membership, which will include corporations, individuals who may be employees of such corporations, and trade associations. The body plans as a part of its routine to carry on certain researches and to direct standardization, legislation, the training of welders and the dissemination of publicity on the whole subject of welding.

Chalkis Mfg. Co. Will Not Bring Out New Car

DETROIT, March 11—The Chalkis Mfg. Co., organized at the outbreak of the war for gun production, will devote its efforts to commercial automotive production, but the exact nature of its product has not been decided upon at this time. The company proposed to bring out a new automobile, but this project has been abandoned.

Indianapolis Entries to Date

NEW YORK, March 6—Five entries to date have been made for the Indianapolis Speedway race May 31. These include two Sunbeams, entered by L. Coatalen for the Sunbeam company, a Chevrolet, driven by Durant, and a Hudson, driven by W. W. Brown. Christiaens will drive one of the Sunbeams. The pilot of the second has yet to be selected. Ralph Mulford, as already stated, will drive a Frontenac.

This will be the seventh annual international race meet at this track and will include cars under Class E, or non-stock type of 300 cu. in. or less, with maximum weight at 2500 lb. Prize money will total $50,000 and the Prest-O-Lite trophy and the Wheeler-Schebler cup will be included.

Both Sunbeams will have six-cylinder engines, 3.2 x 6.14, giving cu. in. capacity of 298. The four-cylinder Chevrolet entry's cubic capacity will measure 296.8, with cylinder dimensions of 3 13/16 x 6 7/12 in. The Hudson entered will have twenty-four valves and a piston displacement of 288 cu. in. Its bore is 3½ in. and the stroke 5.

Another Foreign Driver for Indianapolis

PARIS, March 10 (Special Cable)—Another foreign driver has signified his intention of entering the 500-mile race on the Indianapolis Speedway, May 31. He is Andre Boillot, brother of Georges, and will drive a Peugeot.

Officials Undecided About Status of Self-Imported Airplane

WASHINGTON, March 7—Customs authorities have encountered the first case of an airplane imported into the United States under its own motive power. An American bought a Canadian plane, and it was flown across the border near Detroit.

The question then arose as to whether itwas dutiable, since airplanes are not mentioned in any tariff acts. Customs officials finally decided that if it remains permanently in the United States it should be taxed as a "manufactured article" at the rate of 20 per cent, but if it flies out of the country again within 6 months it will be regarded as "on a tour" and will not be taxed.

Tractor Demonstration at Macon

MACON, GA., March 13—Governor Dorsey opened the first of the six tractor demonstrations planned for this season by the National Implement and Tractor Manufacturers' Association yesterday afternoon. It is under the auspices of the Dixie National Power Farming Demonstration, with A. E. Hildebrand, general manager. The exhibition was postponed until yesterday because the field was too wet, and was confined to a parade and street demonstrations. The Chamber of Commerce invited tractor makers to view the surrounding country. They were enthusiastic about soil conditions and look forward to power farming in this territory on a great scale.

Several tractor concerns staged individual exhibits to show the special features peculiar to their own make. On Monday night seven Molines paraded through the city lit with electric lights, to demonstrate their night operating possibilities. The Case is operating a thresher on a street corner and is also showing the cutaway revolving model in the Hotel Dinkler. Hart-Parr demonstrated the strength of its steering cables by lifting the tractor's own weight by them. Other models shown here include Holt, Huber, Illinois, Lauson, Parret, Frick, Cleveland, Fordson, Lacrosse, Avery, International, Oliver, Emerson Brantingham, Beeman and Alama. The Western Electric Company's farm lights are shown at various salesrooms. Merchants are also displaying parts of implements, plow shares, etc., in their windows with various other merchandise that helps give the tractor atmosphere. Many people here are seeing tractors for the first time, and their impression is quite evident from the fact that every-one is talking tractors.

France Proposes New Import Duties

PARIS, March 12 (Special Cable)—The International Congress of Automobile Manufacturers has voted in favor of a 10 per cent import duty on European cars, and the European members of the Congress voted unanimously that a 45 per cent duty be imposed on cars of American manufacture.

The foregoing cable is printed as received from the European representative of AUTOMOTIVE INDUSTRIES, W. F. Bradley, but there is some doubt as to the constitution of the Congress to which reference is made. It is assumed that it is connected with the Lyons Fair, which is now being held, and at which several American car manufacturers are represented through their French agents. It may be remarked that at present the duty on cars and trucks imported from America into France is 70 per cent ad valorem on vehicles weighing less than 2500 kilos, and that importation is allowed only in the infrequent case where a license is granted.

Kelly-Springfield Tire Re-elects Directors

NEW YORK, March 11—The annual meeting of the stockholders of the Kelly-Springfield Tire Co., held in Jersey City to-day, resulted in the re-election of all the retiring directors.

The board of directors consists of President Van H. Cartmell, Vice-President Stephen Peabody, Secretary F. A. Seaman, Sales Manager O. R. Cook, A. L. Scheuer, J. Oppenheim, A. M. Poole and B. Maas.

Men of the Industry

Changes in Personnel and Position

Van Dervoort in Europe to Study Industrial Conditions

EAST MOLINE, ILL., March 8—W. H. Van Dervoort, president of the Moline Automobile Co., recently sailed for Europe as a member of the commission ordered by the National Industrial Conference Board to visit England, France, Belgium and Italy, to study industrial conditions. It is expected he will be gone some months.

—

Stanley D. Livingston, who was in charge of the apparatus design and drafting section of the Signal Corps Radio Laboratory, Camp Albert Vail, N. J., until his release from the army, has been appointed designing engineer for the Connecticut Telephone & Electric Co., Meriden. He was, for a time, connected with the New York Edison Co., and was also assistant chief engineer of the Disco Co., Detroit, which position he resigned to become engineer in charge of the electrical installation at Camp Merritt, N. J.

—

C. F. Hepburn has been appointed director of sales for the Torbensen Axle Co., Cleveland. For the past year and a half he was a major in the Ordnance Department.

—

J. H. Malone, advertising director of the Automobile Trade Journal, Philadelphia, for nine years, has resigned to accept a position as vice-president and general manager of the Hudson Motor Specialties Co., Philadelphia.

—

Loyal E. Thompson has been appointed assistant manager of the service department of the Republic Motor Truck Co., Inc., Alma, Mich. He was formerly connected with the service department of the Cadillac Motor Car Co.

—

R. E. Clingan, for the past eleven years representative of the Hess Bright Mfg. Co., has been appointed sales manager of the Bock Bearing division of the Standard Parts Co., Cleveland. W. P. Culver will continue as sales manager of the Perfection spring plant, B. A. Quayle as sales manager of the Standard welding plant, Dan C. Swander as supervisor of sales, B. R. Winborn, manager of the Perfection heater and jobbing divisions, and James A. Braden, advertising manager.

—

T. A. Cressey has been appointed sales manager of the Cole Storage Battery Co., Chicago. For the past three years he was district sales manager of the Philadelphia Storage Battery Co., and for several years previous was sales engineer of the Electric Storage Battery Co.

—

J. F. Mackin has joined the Black & Decker Mfg. Co. as its Ohio representative. He was formerly connected with the Independent Pneumatic Tool Co.

Changes in Carlisle Tire Force

ANDOVER, MASS., March 11—A new central manager and treasurer have been added to the Carlisle Cord Tire Co. organization. A. G. Langher, former central district manager for the Diamond Rubber Co., and connected with it for the past ten years, has been appointed to the same position with the Carlisle Cord Tire Co., with headquarters at Chicago. L. H. Homer, treasurer of the Smith & Dove Mfg. Co., Andover, and previous to that, connected with Stone & Webster Management Association, Boston, has been made treasurer.

Capt. Sykes to Represent Dutilh-Smith

NEW YORK, March 8—Capt. George Sykes, R. A. F., A. M. I. E. E., who has been in this country nearly four years, attached to the British War Mission in a commercial capacity, is to be the London manager of the engineering and railroad departments of Dutilh-Smith McMillan Co., when he returns to England in May. His London office is Central Buildings, Totehill Street, Westminster.

Buckwalter Heads American Bureau of Engineering

CHICAGO, March 11—C. J. Buckwalter, formerly manager of the company, was elected president of the American Bureau of Engineering at its annual meeting.

—

S. R. Swiss has been placed in charge of the advertising department of the Republic Motor Truck Co., Alma, Mich. He was recently associated with the Ivan B. Nordham Co., poster advertising, Pittsburgh. Blaine McGrath, former advertising head, is going into the sales department to cover territory in four southern states.

—

Earl Englander, for 10 years a member of the firm of J. A. Englander Co., custom automobile top maker, is now manager of its Detroit plant.

—

Chester Naramore has resigned as Chief of the Petroleum Division, Bureau of Mines, Department of the Interior, and is now associated with the Union Petroleum Co., Philadelphia.

—

Sidney H. Copper, who was associated with Howard E. Coffin, vice-president of the Hudson Motor Car Co., during the existence of the Aircraft Production Board, and later with the National Automobile Chamber of Commerce, Washington office, has opened a stenographic office in Washington especially for visiting members of the automotive industry.

McMullen Leaves Chevrolet for Own Enterprise

FLINT, March 10—B. J. McMullen, general sales manager of the Chevrolet Motor Car Co., has resigned to enter business for himself in Minneapolis, where he will distribute Republic trucks. C. C. Meade, who was assistant to Mr. McMullen, succeeds him.

—

Allan H. MacCaffrey, former publicity manager of the S.K.F. Ball Bearing Co., Hartford, Conn., has become general sales manager of Hollister, White & Co., Inc., investment bankers of Boston.

—

New Nash Distribution Co.

SAGINAW, March 7—R. P. Bishop has resigned as assistant sales manager of the Nash Motors Co. and will distribute Nash cars and trucks under the firm name of the Nash Saginaw Motors Co. L. A. Wilson, who was also identified with the Nash factory, is his partner.

—

Templeton Heads Detroit Board of Commerce

DETROIT, March 8—Allan A. Templeton, president of the Detroit Seamless Steel Tubes Co., has been elected president of the Detroit Board of Commerce for 1919 and 1920.

—

Detroiter Heads Metal Contractors

KALAMAZOO, March 9—Three Detroit men were elected to office in the Michigan Sheet Metal Contractors Association which closed its annual convention here Friday. A. Berschbach was re-elected president. A. F. Prudsch was named a member of the executive committee. H. E. Doherty was chosen vice-president of the traveling men's auxiliary.

Other officers are: Vice-president, Frank Dailey, Jackson; secretary, F. E. Eberle, Grand Rapids, and treasurer, J. A. Shouldice, Battle Creek. The executive committee is composed of Adam Shapper, Bay City, and Harry Rhodes, Grand Rapids. Other officers of the travelers' auxiliary are: President, Harry Snow, Kalamazoo; secretary, L. H. Pearce, Grand Rapids; treasurer, E. E. Bohler, Grand Rapids.

—

Globe Tire Re-elects President

TRENTON, March 11—Joseph B. Linerd was re-elected president of the Globe Rubber Tire Mfg. Co. for a second term at the annual meeting of the stockholders of the company. Before his connection with the Globe organization he was with the Goodyear Tire & Rubber Co. and was later sales manager of the Ajax Rubber Co.

—

Stewart-Warner Re-elects Officers

CHICAGO, March 8—The retiring officers of the Stewart-Warner Speedometer Co. have been re-elected. C. B. Smith is president, V. R. Bucklin, vice-president; W. J. Zucker, secretary, and T. T. Sullivan, treasurer.

Luncheon given by the Splitdorf Electrical Co. on the occasion of the visit of the Society of Automotive Engineers to the company's main manufacturing plant at Newark, N. J., Friday, March 7

Fisk Rubber to Divide Sales Territories

NEW YORK, March 11—The Fisk Rubber Co. will divide its New York and New England territories into two separate sales districts, known as the New England district, with Walter Oakes as district manager, and Western New York District, with G. T. Newton as district manager.

Mr. Newton has been in charge of Fisk sales in the two territories for the past three years. He will now have supervision over eight direct factory branches, including Buffalo, Syracuse, Rochester, Utica, Binghamton, Elmira, Albany and Erie, Pa. His headquarters will be at Rochester. He has been with the company for four years, first as a special representative of the sales department and the last three years as district manager.

Mr. Oakes has been with the Fisk organization for 12 years. He has been branch manager at Boston for some time, and will combine this work with his duties as district manager.

—

C. O. Caniff, assistant to R. W. Langenbacher, sales manager of the Duplex Truck Co., Lansing, has been made superintendent of the eastern sales zone, with headquarters at Atlanta, Ga.

—

William A. Kent, formerly manager of the Kawneer Mfg. Co., Niles, Mich., has resigned to join the S. J. Fitzgibbons Co., manufacturers of tubing and tube products, with headquarters in Detroit.

—

A. H. Sarvis has resigned as sales manager of the Flint Varnish & Color Works, Flint, to become associated with the Willys-Overland Co., Toledo.

—

F. H. Prescott, formerly designing engineer in the automotive equipment section of the Westinghouse Electric & Manufacturing Co., has joined the staff of the Remy Electric Co. as designing engineer on motor and generator equipment.

Carl J. Spitzley, former retail sales manager of the Studebaker Corp. of America, Detroit branch, has resigned to become associated with the W. D. Block Motor Co., Detroit. W. J. Lannon, in charge of the Studebaker branch at Toledo, has also resigned to join the Block organization.

—

C. A. Riegler, Cleveland, has resigned a connection of twenty-five years with the William Edwards Co. to become director of sales for the Ohio Trailer Co.

—

Frank G. Eastman, advertising manager of the Packard Motor Car Co., resigned his position, effective March 1, and has joined the staff of the Lincoln Motor Co., Detroit.

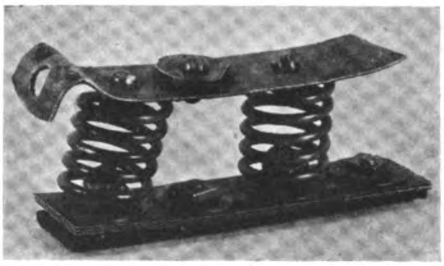
—

W. H. Holmes, who has been connected with the George H. Dyer Advertising Co., New York City, which handles the Packard, has been appointed advertising manager of the Packard Motor Car Co., Detroit, to succeed Frank G. Eastman, resigned.

—

Lt. Russell Wherrett has resigned from the aviation section of the army and has become manufacturer's representative for the Michigan territory for the Doble-Detroit kerosene burner, which is produced by the Doble-Detroit Steam Motor Co., Detroit.

GERMAN STEEL SPRING TIRE



Contains three plies of spring steel on outer band which is bolted with leather strip—See description on page 483 of Feb. 27 issue of AUTOMOTIVE INDUSTRIES

Weir Heads Canada Foundries

BROCKVILLE, CAN., March 10—At the annual meeting of the Canada Foundries & Forgings Co., Ltd., the following officers were elected: President, W. M. Weir, Montreal; vice-president, J. Gill Gardner, Brockville; secretary and treasurer, J. H. A. Briggs, Brockville. Directors elected were: T. J. Dillon, Welland; G. P. Graham, Brockville; Lieut.-Col. Monsarratt, Ottawa; Lieut.-Col. Smith, Montreal; H. Howser, Toronto; H. Bertram, Dundas, and W. J. Shaughnessy, Montreal.

—

H. H. Pete, for several years in the sales department of the Toledo Scales Co., Toledo, has resigned to take charge of the sales promotion department of the Miller Rubber Co., Akron.

—

Neil MacCoull has returned from duty in France with the Naval Air Forces and is now connected with the Texas Co. as automotive engineer in the sales department, with headquarters in New York. Just prior to enlisting he was acting as a mechanical engineer in the machine works of the Westinghouse Electric & Mfg. Co., Pittsburgh.

—

L. H. Benson has been appointed production manager of the Parker Axle & Products Corp., New York, at its Connecticut plant. Prior to his service with the Government, he was identified with the Minneapolis Steel & Machinery Co. as superintendent and previous to that was with the Triumph Electric Co., Cincinnati.

—

Frederick W. Krebs, recently with the Aircraft Production Board, is again affiliated with the United Alloy Steel Corp. and is in charge of its Cleveland sales office, 614 Swetland Building.

—

H. J. Russell has been made chief of the newly created Maxwell-Chalmers export department. He will leave for England in 10 days.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

4000 Columbias in 1919

DETROIT, March 6—The Columbia Motors Co. last week finished its war orders and is now swinging back into peace production. This company built 500 war trucks, 1200 kitchen trailers and completed the larger portion of a $750,000 contract for spare and repair parts. It plans to turn out 4000 passenger cars this year and is at present running ten daily.

Lull Trucks Ready for Quantity Production

WAUSAU, WIS., March 10—The Lull Truck Co., organized about a year ago to take over and develop a quadruple drive design of motor truck, has completed its experimental work and is ready to undertake quantity production. This city will give the company the use of a 30-acre site, including an unfinished manufacturing building, at a nominal rental, with option to purchase within three years from April 1, on condition that the building be completed and equipped, and certain other requirements met by the company. The plant is located on the main line of the Chicago & Northwestern R. R. Karl Mathie of this city is secretary.

Victory Mfg. Co. Will Make Spark Plugs

SPRINGFIELD, MASS., March 10—The Victory Mfg. Co., which has bought the assets of the Gibson & Hollister Co., Springfield, Mass., and Boston, has completed negotiations for the factory building and equipment of the Upson-Martin Co. The new corporation will manufacture spark plugs for tractors and trucks, as well as the Croxford tool and electrical specialties.

Aeromarine on Pre-War Basis

KEYPORT, N. J., March 7—The Aeromarine Plane & Motor Co. has got back into production on a pre-war basis and has reduced its working force. The construction of the 1-story building, 60 x 100 ft., for the New Jersey Motor Sales Co., which builds engines used by the Aeromarine company, has been resumed.

Moline Plow Working for Daily Production of 150

MOLINE, ILL., March 8—The Moline Plow Co. is assembling 50 to 60 tractors per day at present and is working toward a production of 150 per day by the middle of summer. The company is about to install an oven-drying system through which the tractors will be moved on a continuous chain. There is considerable congestion of factory space where air drying is used for the two coats of paint on the final varnish coat. All the engines for the Moline tractors are now being manufactured in the Wilson Foundry & Machinery Co., Pontiac, one of the John Willys plants.

Airplane Experiments

ITHACA, March 7—The Morse-Thomas Aircraft Co. is doing experimental airplane work.

The New 1-Ton Acason

DETROIT, March 6—The new 1-ton Acason truck made its first appearance to the public at the automobile show in the exhibit of the Acason Motor Truck Co. This truck carries a 3¾x5¼ engine. The rear construction is a Timken worm drive, with a three-piece driveshaft. The radiator is of the cast-tank type. It is equipped with a Fuller transmission and multiple disk clutch; Levine steering gear; Eisemann magneto and 36x6 pneumatic cord tires.

Reduction Made in Disco Prices

DETROIT, March 7—The Disco Electric Mfg. Co., Detroit, makers of Disco starting and lighting system for Ford cars, has reduced its price from $100 to $70.

Signal to Make 1000 Trucks

DETROIT, March 8—The Signal Truck Co. is back in commercial production and plans completing 1000 vehicles in 1919.

Republic Finishing Up War Work

ALMA, MICH., March 8—The Republic Motor Truck Co., Inc., is completing an order for 5000 trucks for the Government and is devoting the greater portion of its time to its commercial work. It hopes to be hitting its normal capacity of 3000 trucks monthly soon, but at present its production is considerably below. Shortage of material is seriously affecting production at present, but this situation is rapidly clearing up.

Hall to Build 1000 Trucks

DETROIT, March 10—The Lewis Hall Iron Works is again back on a peace basis after completing 500 machines for the Government. The schedule for the coming year calls for the production of 1000 trucks. This company entered the truck manufacturing field in 1915, producing 100 3½-ton models. The second year it brought out the 2 and 5-ton worm drive model and also the 5 and 7-ton chain drive truck. The first two years most of the trucks were sold along the Atlantic seaboard, but they are now being distributed nationally.

Commerce to Use Pneumatic Tires Exclusively

DETROIT, March 8—The Commerce Motor Car Co. has discarded solid tires as part of the equipment of its 2-ton truck and all new machines of this type will have pneumatic tires. The 1 and 1½-ton trucks will be equipped with either pneumatic or solid tires, according to the wish of the purchaser.

Cameron to Build Tractors

STAMFORD, CONN., March 6—The Cameron Motors Corp., formerly manufacturer of passenger cars, will produce a farm tractor to be known as the Cameron. Specifications of the machine, which it is said have been tested for two years, include a block 4⅜ bore, 6-in. stroke, 4-cylinder engine, with force feed and splash lubrication, kerosene or gasoline carburetor, ignition by generator and storage battery, sectional radiator, etc. The machine has four wheels with two drive wheels at the rear, 42 in. in diameter, 12 in. face. Length is 120 in., width 56 in., height 54 in. and weight 3000 lb. The gearset has three forward speeds and reverse.

Chandler Speeds Up Production

CLEVELAND, March 8—The Chandler Motor Car Co. produced 1200 cars during February, but expects its production to exceed the 2000 mark in March. Reconstruction work seriously interfered with the February output, but now the shift from war to a peace basis is about complete. The Chandler schedule calls for 18,000 cars in 1919. Of this production, the company expects to ship 2000 to foreign countries.

Stinson Tractors Busy on Canadian Orders

MINNEAPOLIS, March 10—The tractor manufacturing plant recently established here by the Stinson Tractor Co. will undertake immediately an order for 300 machines placed during the show here by Martin & Phillips, Medicine Hat, Canada. Delivery is to be made at the rate of 50 per month, commencing April 1. The initial capacity of the Superior works was one machine a day, which is now being more than doubled.

Harrison Radiator Opens Detroit Office

DETROIT, March 11—Sales, inspection and service departments of the Harrison Radiator Corp., Lockport, N. Y., have been opened here at 3066 West Grand Boulevard.

Baker & Lockwood Open New York Branch

NEW YORK CITY, March 10—The Baker & Lockwood Mfg. Co., Kansas City, will open a factory branch here to supply eastern trade.

McGraw Tire Offices Moved to Cleveland

CLEVELAND, March 10—The executive and general offices of the McGraw Tire & Rubber Co. have been transferred here from East Palestine, O., to 1900 Euclid Avenue. A sales and service station has also been opened at 1904 Euclid Avenue. Production plans of the company indicate expansion from 5,000 to 10,000 tires and tubes a day.

Union Truck Pays First Claims

NEW YORK, March 10—The bankrupt Union Truck Mfg. Co. paid a dividend of 2½ per cent March 8.

National Surplus $138,609 Ahead of Year 1917

INDIANAPOLIS, March 11—The balance sheet of the National Motor Car & Vehicle Corp. for the year ended Dec. 31 shows net sales amounting to $2,880,757, and a gross profit on sales of $484,964. The surplus of $1,550,821 for 1918 is $138,609 more than $1,412,212 of 1917.

Comparative financial statements for 1918 and 1917 show:

Executive Committee Will Help Premier President

INDIANAPOLIS, March 13—A committee of three has been formed to take over the active management of the Premier Motor Corp. This committee is just another name for the manufacturing committee which has been in control of several phases of the company's activities for the last few years, and is composed of the same members: C. S. Crawford, F. T. Nehrbas and E. F. Schaeffer. The manufacturing committee has been changed to the executive committee so that it can take over some of the duties of the company's president, A. C. Flowers, who is unable at this time, because of other financial interests, to devote all his attention to Premier affairs.

Ford States Plans

(*Continued from page* 604)

the Ford Motor Co. and he will not be allowed to leave the firm and start a competitive business," said Mr. Stevenson.

"Both Ford's genius and his name are under contract. The Ford organization will not allow him to withdraw these without legal protest and the courts will certainly uphold the present company. Mr. Ford is also under contract to give all his inventions to the Ford Co. There are men connected with the Ford plant fully as competent as either Mr. Ford or his son to carry on the business, so the protest is not because of the loss of their services, but because of the nature of the new business in which they threaten to engage. They cannot interfere with the success of the Ford Company."

In an interview Edsel Ford is quoted as saying that the Fords would not dispose or their interests in the present Ford company. He said no attempt would be made to force the minority stockholders out of the company. He said the new company would be owned entirely within the Ford family and thus directed without outside interference.

He said the plant would be divided among many cities. All factories will not be built simultaneously. Construction work will start the early part of next year. The first three units will go up in Troy, N. Y., Hamilton, O., and Kansas City. The first factories will be complete, but later each one will be devoted to the manufacture of individual parts. The present Ford system of assembly plants will be followed by the new company.

The Ford plan has created a sensation in business and automotive circles. Automobile manufacturers declare Ford is preparing to tackle his greatest undertaking and there are many who declare that even Henry Ford and his millions are not big enough to swing the deal. They say grave problems face him before he can cut loose from his present company and start production for himself. Costly litigation over patents, contracts, trade-marks, etc., is bound to result and these will consume time as well as cash.

To produce a cheap car such as Ford proposes will require an immense plant capable of great production, for it is pointed out that such a car, to sell at so low a price, must be turned out in great quantities if the venture is to prove a financial success. To build such a plant and reach sufficient production will reuire three or four years car makers believe. They point out that it has taken two years to build up his tractor plant to a point where it will produce 400 tractors daily, and say he must build on a much greater scale if he hopes to get into automobile production with reasonable speed.

Chandler Net Profits $2,194,618 for 1918

CLEVELAND, March 11—Net profits of the Chandler Motor Car Co. were $2,194,618 for the year ended Dec. 31 last, and adding that to the surplus for Jan. 1, 1918, of $2,663,189, a surplus of $3,381,905 is totalled for the year. Net profits for 1918, however, are $187,785 less than the $2,382,403 earned in 1917. The balance sheet for the past three years compares as follows:

Assets

	1918	1917	1916

New Cleveland Plant to Cost $650,000

CLEVELAND, March 11—The new plant of the Cleveland Automobile Co., recently organized by Chandler Motor Car Co. officials to produce a $1,300 car, will cover approximately 200,000 sq. ft. of floor space and will cost $650,000. The plant will be completed and the company in operation by July 1. The site of the new factory has not been definitely decided upon.

—

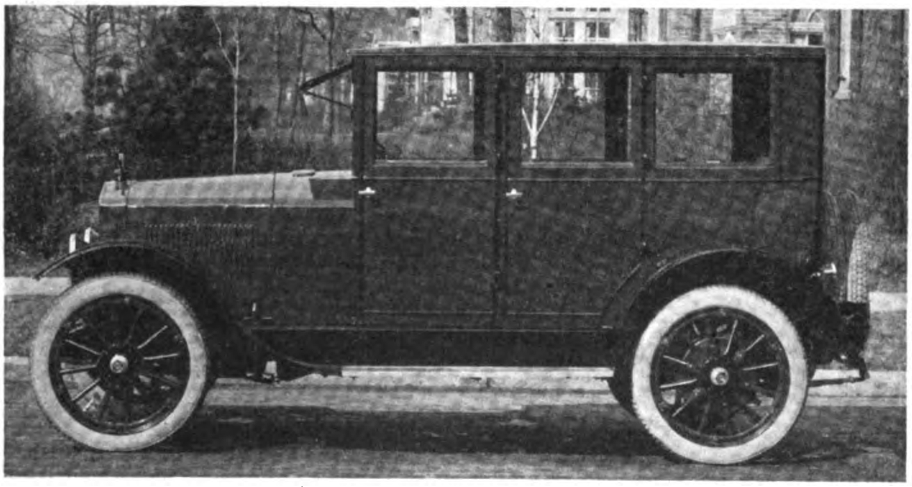
Barley Plans Increased Production

KALAMAZOO, March 12—The Barley Motor Car Co. is at present producing at the rate of 6 cars a day, and plans to increase. Recently the company's buildings were completely rearranged with this increase in production in mind.

—

Wilson Foundry Adding

PONTIAC, March 11—The C. B. Wilson Foundry & Machine Co. proposes to increase its capacity by the construction of a new building unit 100 x 800. Work is under way and the structure should be completed within 90 days.



THE Essex Co. is exhibiting for the first time at the Detroit show its sedan model. This follows in many respects the square lines of the sedan on the Hudson chassis and is finished in the same dark green as the touring model. The upholstery is in whip-cord. The front seat has a solid back, and the seating capacity is five passengers. The car will sell for $2,250 f.o.b. Detroit

*Tentative dates.

CONVENTIONS

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

FOREIGN TRADE OPPORTUNITIES

WASHINGTON, March 7—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has inquiries for the agencies of automobiles and accessories. Full information regarding each of the following can be secured by addressing the Bureau of Foreign and Domestic Commerce and referring to the Foreign Trade Opportunity number:

A firm in England desires to buy outright or to act as agent for the sale of cheap but serviceable cars, two to three for the first order, and parts and tools suitable for garage work. Terms, cash or credit, one to three months. Cash for first order. References.

A firm in Ireland desires to secure an agency for the sale of motor cars and motor accessories for the whole of Ireland. References have been filed. Foreign Trade Opportunity No. 28,340.

A commercial agent in France desires to secure an agency for the sale of motor car accessories. Correspondence may be in English. References have been filed. No. 28,342.

A man in France desires to secure agencies for the sale of rubber tires and automobiles. Correspondence should be in English. No. 28,345.

A man in France wishes an agency for the sale of automobile accessories. Correspondence may be in English. References have been filed. No. 28,422.

A man in France wishes to secure an agency for the sale of motorcycles with side-car attachment. References have been filed. Foreign Trade Opportunity No. 28,466.

A firm in Denmark desires the agency for automobiles and motorcycles and all accessories, including tires. Quotation should be made f.o.b. New York. Terms, cash. Letters may be in English.

An engineer in Italy desires an agency for the sale of farm tractors. Correspondence may be in English. Foreign Trade Opportunity No. 28,403.

A man in France wishes to represent American firms in the sale of farm tractors. Correspondence should be in French. No. 28,404.

A man in France wishes to secure an agency for the sale of automobiles and tractors. Correspondence should be in French. No. 28,411.

A commercial agent in Algeria desires an agency for the sale of farm tractors. Correspondence should be in French. References have been filed. No. 28,393.

A firm in Switzerland desires an agency for the sale of farm tractors. Correspondence may be in English. References have been filed. No. 28,399.

A man in France wishes to be placed in communication with exporters of farm tractor with a view to its introduction in that country. Correspondence should be in French. No. 28,488.

A man in Syria desires to secure representation of American firms for the sale of farm tractors in Armenia. Correspondence should be in French. No. 28,491.

Proper Systems Reduce Labor Turnover

Wide Variation in Turnover Percentages Due to Factory Methods—Many Plants Have Over 500 Per Cent Yearly

WASHINGTON, March 13—If a worker remains in the factory for more than three months the chances are two to one that he will be permanent. Twenty-one per cent of the men hired in Detroit leave their jobs before they finish one week's work. Fifteen per cent work less than 2 weeks, 14 per cent less than one month, 17 per cent from 1 to 3 months, 11 per cent 3 to 6 months, 8 per cent 6 months to 1 year and after 1 year the percentage decreases rapidly from 6 per cent quitting their jobs after working less than 2 years to 1 per cent quitting after being employed 5 years. This indication of the heavy labor turnover that exists in Detroit is the result of an intensive investigation of this problem by the Department of Labor, which has examined the length of service of workers, the nature of their separations and the causes. A comparison was made between Cleveland and Detroit.

High Turnover in Detroit

Labor turnover was found to be considerably higher in Detroit, where more than one-fifth of the firms had a turnover exceeding 400 per cent and two-fifths a turnover exceeding 300 per cent, as compared with Cleveland, where more than three-fourths of the establishments had a turnover of less than 300 per cent.

The greater turnover in Detroit is due to the more intense competition for labor, especially during the war period, when Detroit concerns seemed most actively engaged in war work. There has, in addition, always been a more noticeable turnover of labor in those cities which confine their activities chiefly to one specific industry. In Akron, where the tire industry is the chief occupation, a similar class of migratory worker floating from one factory to another and back again is also noticeable.

Specially trained executives, welfare systems, well organized labor departments, fairness, good wages, and consideration of promotion and service for employees show definitely in the investigation of the Department of Labor that they tend to lower the turnover.

Considerations That Reduce Turnover

Table 1 shows in detail the extent of labor turnover in 37 Cleveland establishments.

This table shows that more than 60 per cent of the Cleveland firms had an annual turnover exceeding 200 per cent, while 25 per cent of the companies exceeded 300 per cent.

There are no companies listed with a turnover of less than 50 per cent, 4 are under 100 per cent, 5 under 150 per cent, 5 under 200 per cent, 7 under 250 per cent, 7 under 300 per cent, 5 under 350 per cent, 4 under 400 per cent and none over this figure.

Examination of the general causes for the extent of turnover shown was made by investigating those companies with the lower and higher turnover. Establishment No. 17, employing an average of 1004 persons daily, had the largest turnover, 368 per cent, and in this company it was found that there was no attempt made to operate a properly organized

[1]Less than 1 per cent.

employment department, maintain a trained employment executive or in any way give consideration to the workers. In the next largest turnover—359 per cent—which occurred in a storage battery plant employing 1610 daily, it was found that the general character of the work is disagreeable due to the use of odorous chemicals, fine powders and to conditions which of necessity are hot and dusty. The firm has a well organized employment department, but still allows time-keeping clerks and foremen the power of hiring and firing.

Firm No. 1, an automobile and motor truck manufacturer with a well balanced employment organization, where the power to hire and fire rests only with the highest labor executive and where sick benefits, insurance and other welfare schemes are practiced shows the lowest labor turnover—65 per cent per year. This concern employs 4456 daily.

Table 2 shows the extent of labor turnover in 42 Detroit establishments.

It will be noted that one concern has a turnover under 50 per cent, 3 under 100 per cent, 3 under 150 per cent, 3 under 200 per cent, 6 under 250 per cent, 8 under 300 per cent, 4 under 350 per cent, 5 under 400 per cent, 6 between 400 and 500 per cent, and 3 over 500 per cent.

Establishment No. 1, which is undoubtedly the Ford Motor Co., employing an average of 31,950 people daily, as is known, has a very comprehensive welfare scheme and treats its employees liberally and fairly. It will be noted that the Ford company discharges less than 1 per cent of the people leaving its employment each year—

[1]Period covered by separations is different from period covered in Table 1.
[2]This establishment lacked the data for Table 2.
[3]Less than 1 per cent.

169 having been discharged in the 12 months. Establishment No. 6, coke manufacturers, despite the unpleasantness and hazardous nature of the work, maintains a turnover of only 86 per cent a year. This record is the result of a carefully worked out liberal labor policy, the existence of an efficient employment department and the centralization of all functions relating to employment, promotion and service. More than 60 per cent of the employees earn $1,300 annually, ad less than 10 per cent less than $1,200. The firm maintains a medical staff, operates an employees' sick benefit and conducts a co-operative store. Workers with continuous service records are given bonuses. A profit-sharing plan allows for distribution of certain profits each year in proportion to the salaries. Filtered drinking water, lockers and showers, special shaving conveniences, em-employees' lunch room, club rooms, and a special housing plan are maintained.

Establishment No. 40, an automobile car and parts maker, pays no attention to his labor organization, allows foremen to hire and fire, and—the labor turnover is 507 per cent annually.

Nine per cent of the workers in Cleveland and 11 per cent in Detroit were found to have been discharged during the year, 5 per cent and 7 per cent respectively were lost in temporary lay-offs, 5 per cent and 8 per cent entered military service and 81 per cent in Cleveland and 73 per cent in Detroit quit their jobs, which indicates definitely that it is the restlessness of the worker or the offer of better wages or other similar inducements that cause the chief proportion of turnover.

Table 3 shows specifically the number and percent of separations and the causes.

The length of service, which was discussed in the opening paragraph of this article, is shown in tables 4 and 5. ***(Continued on page 667)***

Factors in High-Speed Engine Development

Forced Lubrication — High Mean Effective Pressure — Valve Areas—Inertia Problems—Valve Timing and Materials—Piston Material and Design, All Play Important Roles

D. McCall White Favors Cast Iron Pistons—Tells S. A. E. the Story of Cadillac Engine Development

Part I

By D. McCall White*

DIFFERENT firms have different ideas regarding engines of high efficiency and moderately efficient engines. For very high-speed engines, the designer must not lose sight of the fact that what the public requires to-day is a small engine which has good torque at low speeds and is capable of revolving efficiently at very high speeds.

These two points are difficult enough to attain together, as one is really opposed to the other in practice, due to the fact that in order to obtain high speeds with power, the valve areas, valve ports, carbureters, etc., must not be restricted in any way whatever; whilst, in order to obtain a good mixture at low speeds with heavy torque, means, firstly, a different valve setting and, secondly, more or less restricted port and valve areas, etc., in order to give high gas velocities.

If one adds to the above complications the fact that it is also required that the modern valve gear must be silent, the proposition is one which calls for considerable thought and ingenuity.

Briefly stated the fundamentals of high-speed engines are as follows:

High mean effective pressures at high speeds which depends on:

1—High volumetric efficiency.

2—High compression to help rapid combustion at high speeds.

3—Light reciprocating and rotating parts to obtain high mechanical efficiency.

It is only a few years ago since engines were designed with a maximum power of 1200 to 1500 r.p.m., although other designers had the forethought to consider that it was possible to attain very high engine speeds indeed, and to-day this is an accomplished fact.

The high-speed, high-efficiency engine of to-day must be designed very carefully in order to obtain good results, as one slip will spoil the whole design. We have all lengths of stroke-bore ratios, but the stroke-bore ratio should be from 1.5 to 1 to 1.625 to 1, because one can obtain all the power required without having a very unwieldy and heavy engine.

It should also be considered that there are more fastidious purchasers than ever to-day who buy cars, and therefore there must be no doubt whatever that the engine must be practically free from vibration and must be most sweet, silky and silent when transmitting power. In short, the salable article is the one which has small size coupled with great power and is neat and compact in design, with the requisite silence. There is nothing pleases the owner more than to have these combinations.

I believe I have mentioned many times that a bore of about 90 millimeters is about the maximum cylinder for high-speed work, and after that I certainly believe multiplicity of cylinders should commence.

Mean Effective Pressures

It is quite useless to think of designing an engine to cope with the present-day market unless it can develop power up to from 2500 to 3500 r.p.m. or over, smoothly and quietly. The power must be good and a touring engine of to-day must be capable of carrying a mean effective pressure from 80 to 100 lb. per sq. in., relative to the brake horsepower up to 2200 r.p.m. at least.

A power and mean effective pressure curve might be of interest—Fig. O. The curve shows the mean effective pressure and b.hp. on a 12-horsepower Napier engine designed around 1911 having one L head exhaust valve and

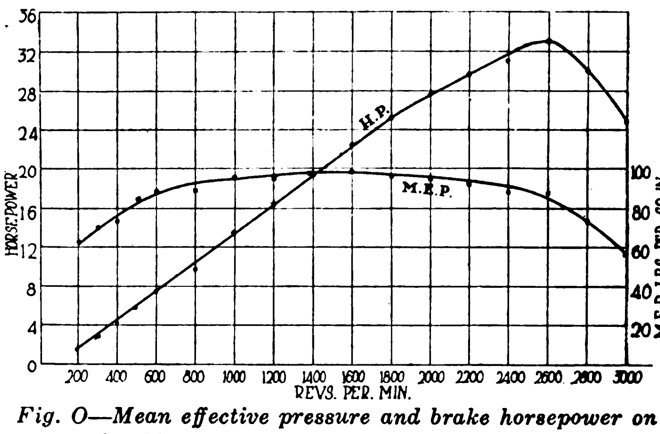

Fig. O—Mean effective pressure and brake horsepower on 12-hp. Napier four-cylinder engine, 2 11/16 by 5

*EDITOR'S NOTE—D. McCall White, vice-president of the Cadillac Motor Car Co., read this paper before the mid-winter meeting of the Society of Automotive Engineers in New York, February, 1919. Mr. White designed the Cadillac eight-cylinder engine, which was the pioneer in high-speed, multiple-cylinder engines in America. Previous to coming to America he was engineer with two or three leading European car makers.

one overhead intake valve immediately above. This engine was a four-cylinder, 2 11/16 by 5 in., and showed a mean effective pressure relative to the brake of 98 lbs. per sq. in., and a maximum power of 33 B. H. P. at 2600 r.p.m. The engine was fitted with a muffler but pulled more power, naturally, without the muffler and had a two-jet carbureter of my own design. The crankshaft had two bearings and had forced lubrication oiling system throughout.

A curve, Fig. 1, shows mean effective pressure and power curve of the standard Cadillac eight-cylinder engine run up to very high speeds of 3750 r.p.m., which is of considerable interest.

Relative to mean effective pressures the table below shows bore and stroke with revolutions per minute and mean effective pressures relative to the brake, which I obtained from seven different engines some few years ago:

Bore, mm.	Stroke, mm.	R. P. M.	M. E. P. Lbs. per Sq. In.
68	127	2400	89
68	127	2000	97.5
82.5	127	1200	82.5
89	127	1200	79.5
96	130	1200	127
80	130	3000	103
80	130	2400	104

Volumetric Efficiency

To design a successful high-speed engine, it is desirable that the compression should be fairly high in order to get rapid combustion at high speeds, and the ratio should approximate 21 per cent of the total volume. A compression curve, Fig. 2, shows how the compression is maintained in the Cadillac eight-cylinder engine.

Whilst on the subject of compression, a very simple and easy method of indicating the compression on the engine, as well as the maximum pressure, can be accomplished by the Okill indicator, an English instrument, and which we have found to be very satisfactory. Fig. 1-B shows this instrument attached to a Cadillac eight and it is easy to see the graduations on the outside cylinder of the instrument. This instrument consists of a cylinder containing a piston of about ½-in. diameter, the piston being held at the bottom of a cylinder by a coil spring.

The cylinder is screwed into a fitting which communicates by a small passage with the combustion chamber and a stop-cock is placed in the passage. The tension of the spring holding the piston on its seat can be varied by a knurled nut at the top of the cylinder, the motion of the piston being transmitted to a pointer at the side of the cylinder. When using this, the knurled nut is screwed down until a considerable pressure is put on the piston, the stop-cock being then opened and the knurled nut backed off until the piston just starts to lift each time the engine comes up on the compression stroke, thus indicating that the spring pressure just balances the compression.

The tension of the spring and consequently the compression indicated, is directly proportional to the number of turns required on the adjusting nut, and the motion of the

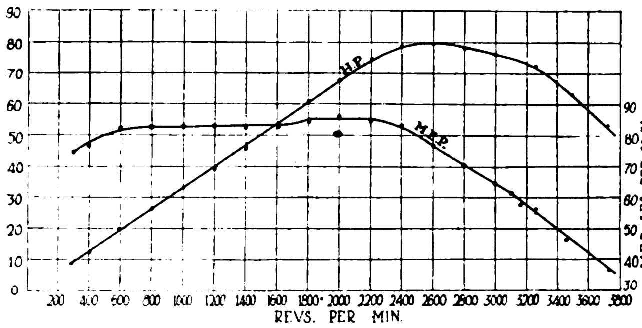

Fig. 1—Mean effective pressure and horsepower curve on Cadillac eight up to 3750 r p m.

nut is indicated in the same manner as the motion of the barrel of the ordinary micrometer, except that it is graduated to read in lbs. per sq. in.

High-Speed Characteristics

The high-speed engine might be likened to an air compressor, as the great point is to get the charge into the cylinders and thus obtain the highest possible volumetric efficiency, and much can be done by the shape of pipes, smoothness of same, lack of bends or elbows, particularly careful design of valve ports, seats, etc., together with the cooling of same.

The volumetric efficiency is entirely dependent upon port area, large carbureters, large valves, etc., but coupled with these advantages is the obvious disadvantage of carburetion and starting in cold weather, which former affects the acceleration to a very great degree. As cold weather is with us every year, it is highly important that precautions should be taken by the designers to see that their enthusiasm for maximum power does not overstep the bounds of proper carbureter size, etc. in order to get a combination of highly satisfactory running, both summer and winter.

A great deal has been done in heating intake manifolds and I propose to deal with this point later. The curve, Fig. 1-A, illustrates the difference on Cadillac eight-cylinder engine in 1915 when using 1¼-in intake manifold as against 1½-in. intake manifold. It will be noted that the power is increased right up the line from 1200 r.p.m. and was about the same at lower speeds.

On the matter of high volumetric efficiency, we have heard a great deal on the question of multiple valves and I do not know whether it is generally known that multiple inlet valves consisting of a group of three intake valves were used in the English Napier car in 1909.

A great deal has been heard of the overhead valve and many types of overhead valve systems have been used. We have seen racing cars with overhead camshafts driven by bevel gears, spur gears, spiral gears, etc.; other valve systems with the camshaft below and push rods with rockers operating the valves above.

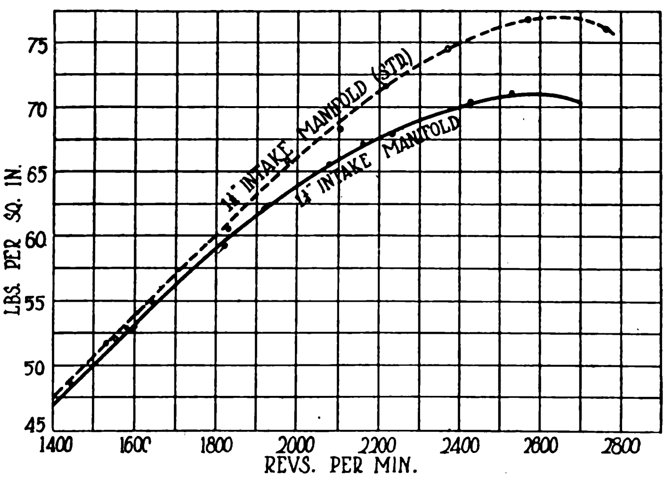

Fig. 1A—Difference in horsepower using 1½-in. manifold as compared with 1¼-in. size on 1915 Cadillac eight

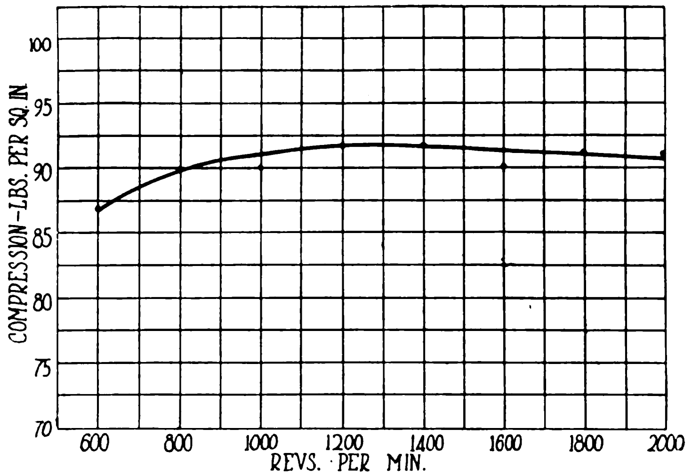

Fig. 2—Cadillac eight-cylinder engine compression curve up to 2000 r.p.m.

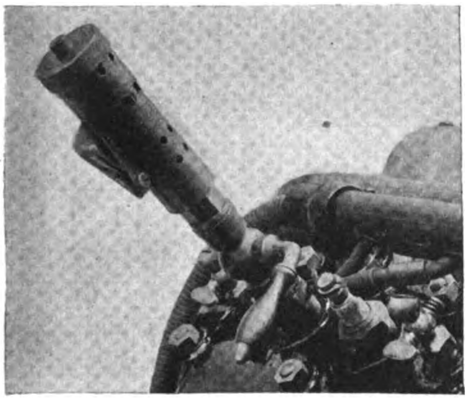

Fig. 1B—The O'Kill pressure indicator for engine tests

The Wimperis accelerometer used in road testing

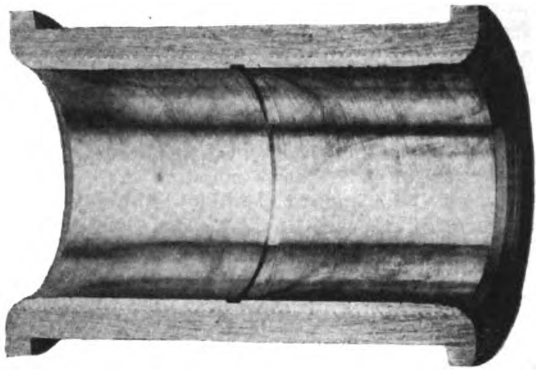

Fig. 8—Circular oil groove in the center of the bearing which serves as an oil reservoir

Much can be said regarding the different types, but I do not believe that it is possible to design a satisfactory and quiet overhead valve mechanism with a combination of rocker arms and overhead camshafts, because of the difficulty in obtaining quiet engines. On the other hand we have a quieter system having the camshaft below and push rods coupled with rocker arms operating the valves above, but I believe that the inertia of this valve mechanism would be so great as to almost put it out of count as the kind of a valve gear which should be designed into a high-speed engine.

Valve Gear Types

When all is said and done, there is a great deal to be said for the L-head type of engine, because the valve gear can be kept down very light indeed, very good sized valves can be used and it is a fact that this, up until the moment, is the quietest type of valve gear which can be used in the touring car engine. It is true that the engine fitted with overhead valves when properly designed should pass approximately 25 per cent more gas than the L-head engine, although a well designed L-head engine uses about 75 per cent of the circumference of the valve, whilst with the T-head engine only about 50 per cent of the circumference of the valve is effective. Where multiple valves are used, it is very easy to see by simple calculation that the frictional resistance offered by double valves and ports is approximately 30 to 35 per cent greater than that of a single valve and port of the same area.

On the question of the inertia of valve mechanism generally, in the Cadillac eight we are obtaining engine speeds on the road of well over 3000 r.p.m. and have records of 3550 and 3850 r.p.m. road performance. If one considers, referring to the valve mechanism, just exactly what this means on the matter of acceleration, which information can easily be obtained by simple figuring, that at 3000 r.p.m. the time taken to open and close one of the valves is .0125 second, at 3550 r.p.m. the time taken to open and close one of the valves is .0106 second, and at 3850 r.p.m. the time taken to open and close one of the valves is .0098 second. You will see, therefore, that the first thing a valve has to do, in a very high-speed engine, after it opens, is to close, and there is mighty little time allowed to do that.

Valve Seat Angles

At various times there have been discussions regarding the different angles for valve seats, and if one takes a seat of 50 degree angle having a supposed lift of ¼ in., this will give a valve area across the narrowest portion of only 72 per cent of ¼ in.; whilst if the valve seat having the same width of seat as the 50 degree seat is 30 degrees, this gives 87.5 per cent of ¼ in.; whilst the 30 degree seat narrowed down to around 1/16 in. gives the same amount of ¼ in., but, of course, gives a larger valve bore, thus decreasing the velocity through the bore itself.

Valve Timing Results

The valve timing of an engine has quite some considerable effect on the power, not only at low speeds, but at high speeds. We ran some power curves on the Cadillac 1916 eight at that time, all of these tests being run on the same engine,

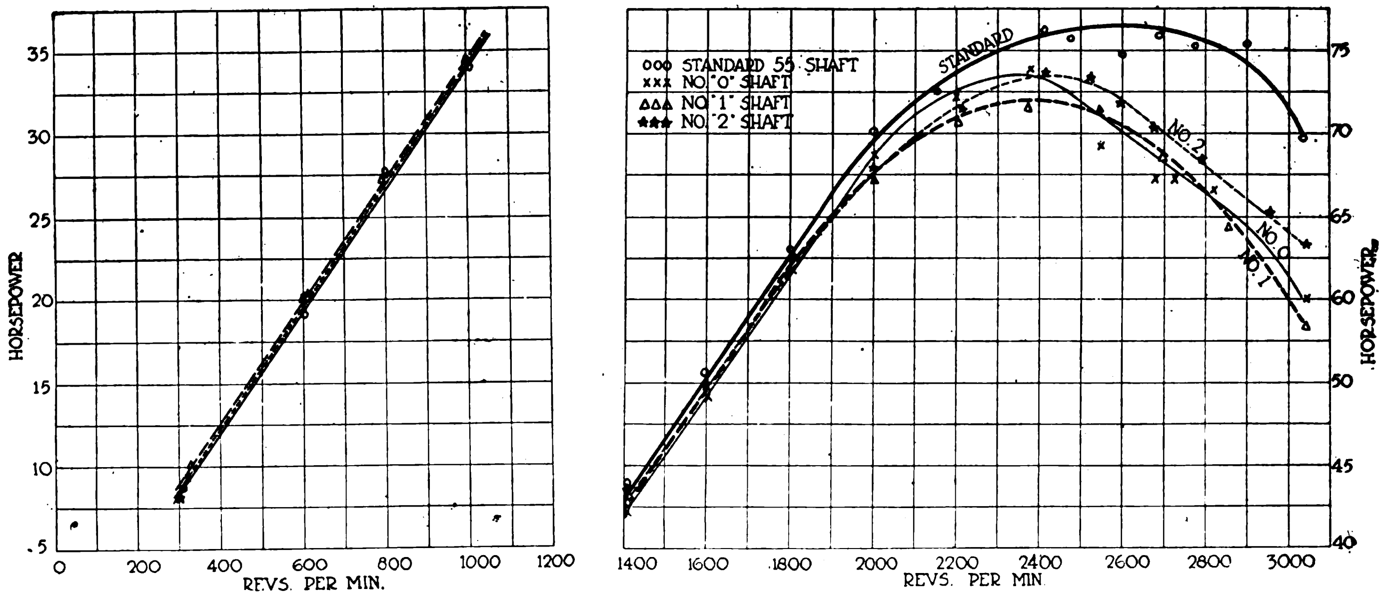

Fig. 3—Cadillac eight-cylinder engine power curves with different camshaft designs

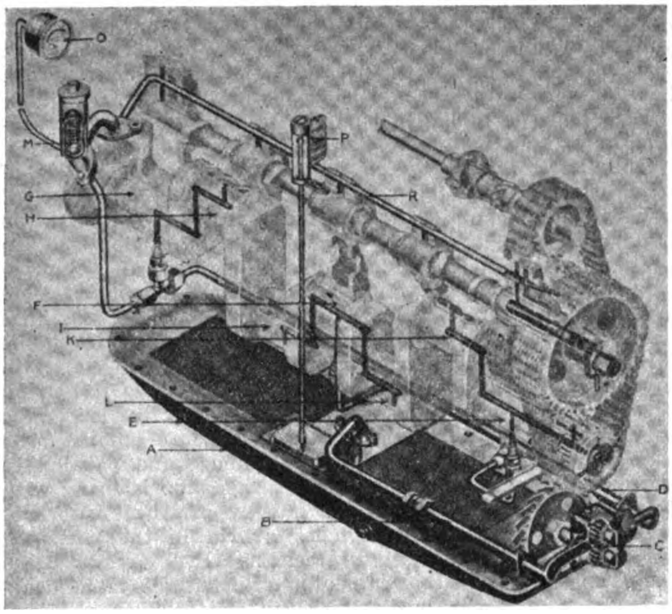

Fig. 7—Cadillac forced feed oiling system

and superimposed curves are shown in Fig. 3. Chart No. 1, which is known as Standard, is the following timing:

	Inlet Opens	Inlet Closes	Exhaust Opens	Exhaust Closes
Standard timing	3° 49′ (A)	47° 29′ (A)	46° 56′ (B)	3° 7′ (A)
No. 0 timing..........	1° 52′ (A)	31° 22′ (A)	47° 52′ (B)	1° 49′ (A)
No. 1 timing..........	2° — (B)	32° 19′ (A)	47° — (B)	1° 10′ (A)
No. 2 timing..........	1° 22′ (A)	33° 7′ (A)	43° 31′ (B)	2° — (A)

Under Fig. 3 is shown horsepower curves superimposed on one another, all of which are self-explanatory, and inspection will show a slight gain in power up to 1000 r.p.m. in favor of the shafts marked No. 0, No. 1 and No. 2, but after that point there is a slow and steady loss up to 2400 r.p.m., where there is a sudden break in the curves, whilst the curve run with the Standard timing shows practically no loss of power up to and around 2800 r.p.m.

Valve Material Specifications

In my opinion, the material used in valves is very important. In England around 1913 when running with engines turning up as high as 300 r.p.m., I used a material in the valves having the following analysis:

	Per Cent
Carbon	0.40
Silicon	0.14
Sulphur	0.03
Phosphorus	0.035
Manganese	0.65
Nickel	5.00

whilst for engines running around 3000 r.p.m. the following anaylsis was used:

	Per Cent
Carbon	0.32
Silicon	0.10
Sulphur	0.03
Phosphorus	0.037
Nickel	3.00

Whilst both these analyses were satisfactory, we always had more or less trouble with valves warping and consequent compression leakage. The analysis of the valves used in the Cadillac eight-cylinder engine should be of interest, as we practically do not know what trouble is, so far as our valves are concerned.

For the intake valves the following analysis is used:

	Per Cent
Carbon	0.69
Manganese	0.32
Sulphur	0.012
Chromium	1.08
Tungsten	2.15
Vanadium	0.08
Silicon	0.15
Nickel	0.15

whilst the exhaust valves have the following analysis:

	Per Cent
Carbon	0.56
Manganese	0.35
Sulphur	0.016
Nickel	0.12
Chromium	3.06
Tungsten	13.84
Silicon	0.17

I have already laid considerable stress on the weight of the valve mechanism, and it is well known that the pistons

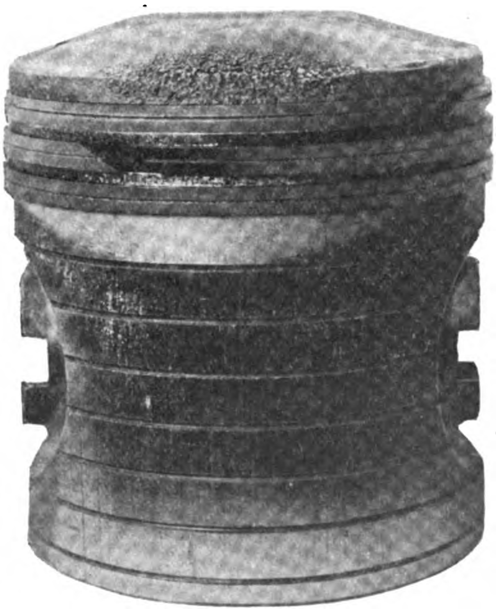

Fig. 4—Aluminum piston after 50-hr. test in Liberty engine, corroded due to changing quality of mixture and intense changes of temperature

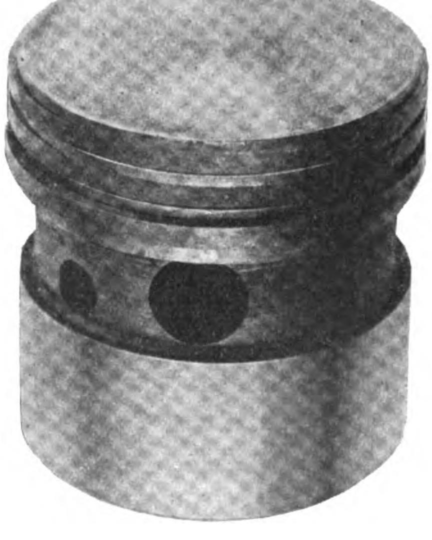

Fig. 5—A Cadillac piston that had not enough surface above the wrist pin and below the bottom groove

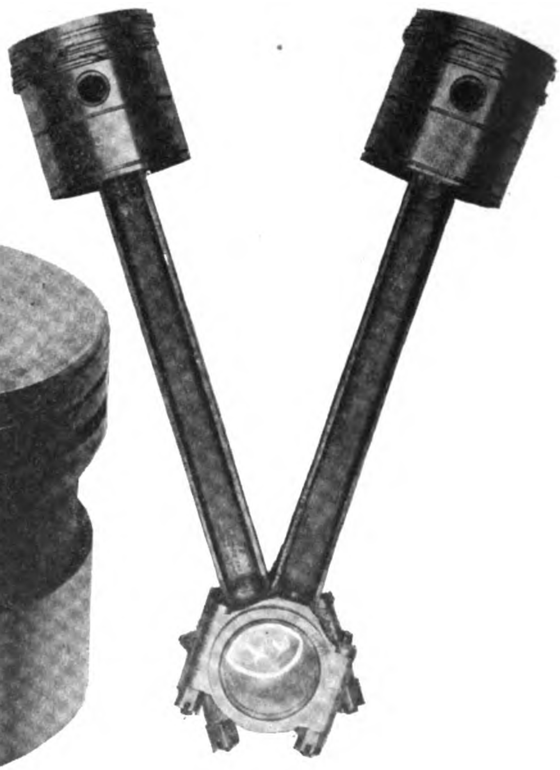

Fig. 6—Standard piston and connecting-rod on Cadillac eight engine

should be just as light as ever possible. I have tried various designs of pistons, including aluminum, steel and cast iron of all different shapes, and up until the moment of writing, so far as the touring car engine is concerned, I have not found either the aluminum or steel pistons to be satisfactory.

In the first place, it is necessary to give both the aluminum and steel pistons very much too great clearances in order to insure quiet running and satisfactory performance of the motor. Where aircraft engines or engines which are continually running at high speeds are concerned, it is possible so far as clearances are concerned that the aluminum pistons are entirely satisfactory, but there is no doubt in my mind that owing to the intense changes of temperature in any motor that the aluminum pistons are apt to be eaten away in very little time.

Fig. 4 illustrates an aluminum piston taken after a 50-hour test on a Liberty twelve, which is considerably corroded and is merely an example of continuous changing of temperature or quality of mixture and its effect on aluminum alloy.

Fig. 5 shows the lightest form of cast iron piston which I have been able to develop up to date, the weight of same being 15 ounces and the diameter being 3⅛ in. The surface above the wrist pin and below the bottom groove was insufficient and the piston wore rapidly at that point.

Fig. 6 shows assembly of Cadillac standard pistons and connecting rods.

Before leaving the pistons, let me mention that in multiple-cylinder, high-speed engines with relatively small bores and large superficial area of combustion chamber walls, it is highly important to prevent the water, which is ever present at combustion, and gasoline, when an enriching carbureter device is used for starting in cold weather, from getting past the pistons into the crankcase, thereby causing stoppage of lubrication by the water becoming frozen, corrosion of parts such as ball bearings, distributer breaker points, where this essential is designed into the engine, crankpin journals and main shaft bearings. This menace cannot be too seriously considered and the only remedy is the accuracy of piston and cylinder fits and proper piston lubrication, all of which goes hand in hand with cast iron pistons in cast iron cylinders. Later on in the paper is given a table of piston clearances which will be of interest also relative to the above points.

Forced Lubrication Essential

I believe it is a well known fact that high speeds or continued speeds under high power cannot be maintained satisfactorily without the use of forced lubrication. One example which we had before us not so very long since was in connection with the Liberty engine, where attempt had been made to feed the connecting rod crankpin end bearings by means of oil thrown from the main bearings. This proved entirely unsatisfactory after tests carried out by Messrs. H. M. Crane of the Wright-Martin Aircraft Corp., John Wilkinson of the H. H. Franklin Mfg. Co. and myself, and was substituted, in agreement with the Government engineers, by forced feed. It is highly necessary that large volume of oil should be pumped under pressure and not merely small volume under pressure, and there should always be reservoirs with separate leads to the bearings.

Fig. 7 shows a diagram of the Cadillac lubricating system, an explanation of the diagram being as follows:

The lubrication is by oil under pressure. A supply of oil is carried in the oil pan A. Oil is drawn from the oil pan by the oil pump C through the pipe B and forced to the main bearings E, F and G, through the supply pipe D. The pressure of the oil is regulated by an overflow valve or pressure regulator M containing a valve under spring tension. When the pressure is reached for which the valve is set, the valve is forced open and the oil overflows past the valve. A small hole drilled in the regulator housing allows oil to by-pass the valve when the valve is seated. Oil flowing through the by-pass and oil forced past the valve is carried to the camshaft bearings and power pressure pump in the gasoline system through the pipe R above and parallel to the camshaft. The forward end of this pipe is fitted with two nozzles from which oil flows into the camshaft sprockets and to the chains through holes drilled in the camshaft sprockets. The connecting rod bearings H, I, K and L, on the crankshaft, are lubricated by oil from the main bearings forced through holes drilled in the crankshaft. The hole is drilled in the crankshaft sprocket through which oil is supplied to the camshaft chain. The cylinders are lubricated by oil thrown from the lower ends of the connecting rods. There is one gauge and one indicator in the lubricating system. The pressure gauge O is located on the instrument board and indicates the pressure of the oil. The indicator P is attached to the upper cover of the crankcase near the carbureter and indicates the level of the oil in the oil pan A.

The Bellis high-speed, double-acting, steam engine, in which design was first incorporated the forced lubrication system, is described by Prof. Ripper in his book Steam Engine Theory and Practice as follows: "The Bellis engine will illustrate the possibility of running double-acting engines at high rotational speed without fear of excessive wear and knocking. It is claimed for it that its success is generally due to the application of forced lubrication, that is, supplying the lubrication to the moving parts under pressure. The pressure required for this proposition is not the maximum pressure on the bearings, but only a pressure sufficient to force the oil into the bearings on the return stroke, when the pressure is reduced on one side of the pin, while on the driving stroke the time is not sufficient to squeeze the oil between the surfaces before the pressure is again reduced and the supply renewed. The difficulty felt in running double-acting engines at high rotational speeds arises from the known necessity of close adjustment of the bearings to avoid audible knock and insure quiet running, and this necessary closeness of adjustment renders the pin and its bearing very liable to get hot and the pin to seize. This liability to seize arises from the fact that, owing to the necessary closeness of fit, any small increase of temperature in the pin causes sufficient expansion to make it overtake the small clearance permissible when cold, and trouble immediately follows from

Table No. 1

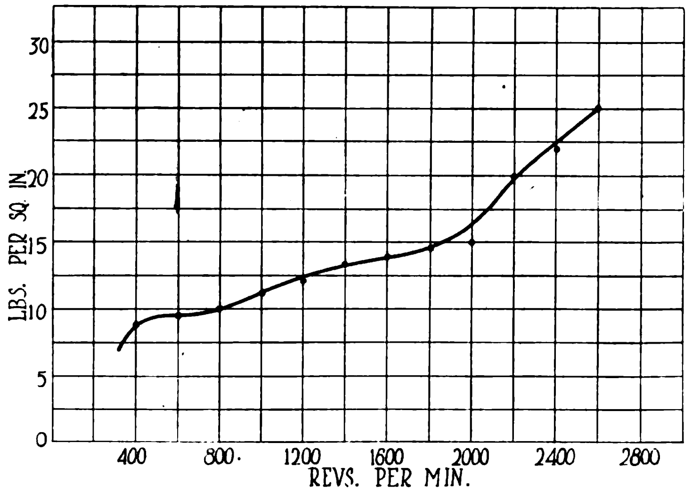

Fig. 9—Oil pressure in relation to revolutions per minute

seizure of the pin. There cannot, however, be any increase of temperature in the pin so long as the pin and its bearing are well supplied with oil between the surfaces—hence the value of forced lubrication."

Particular points in connection with forced lubrication are as follows: Saving in friction which occurs with forced lubrication. Tests were made with oil pressures of varying loads and it was found that the engine was quieter the higher the pressure and the frictional horsepower was, with high oil pressure, only 60 per cent of that without pressure, and 72 per cent with medium pressure of that without pressure.

Results of Bearing Tests

It is interesting to note that we have carried out some very extensive tests on the Cadillac engine at high speeds and have been able to maintain power for periods extending over 400 hours at 2000 r.p.m. without adjusting the bearings. In addition to this we have been able to maintain maximum power at 3000 r.p.m. for 12 hours without stopping, which I consider a triumph for forced lubrication.

Some years ago I carried out some tests having different clearances of pistons, both cast iron and aluminum, with and without extra oil supply to the pistons, and table No. 1 indicates the power developed without extra oil supply, whilst table No. 2 indicates the power developed with extra oil supply. The diameter of pistons was 3¼ in. and the tables themselves are self explanatory as to the results obtained.

On the matter of oil grooves, these should be conspicuous

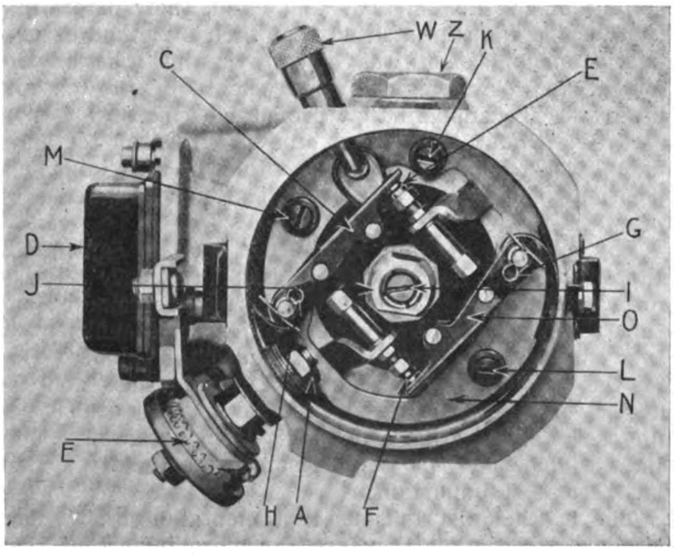

Fig. 10—Cadillac ignition with two sets of contacts arranged to fire alternately

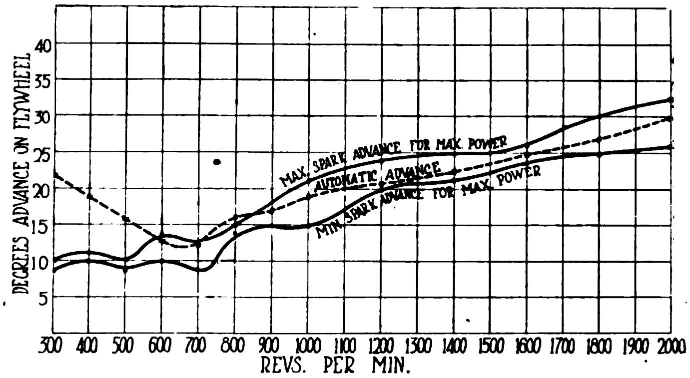

Fig. 11—Curves showing degree of spark advance on the flywheel relative to r.p.m.

by their absence so far as what is known as the ordinary kind of groove is concerned, the only type of groove which I would favor being one which is merely a circular groove around the center of the bearings, which is actually a reservoir and tends to have the oil right around the circumference of the bearing so that it can reach every part of it. Fig. 8 shows a Cadillac bearing with the groove described.

It is important that the oil pressure should be low when throttling, increasing as the speed increases, a system which I have found to be very satisfactory and which is incorporated in the Cadillac engine, a curve Fig. 9 illustrating oil pressure and r. p. m. which is self explanatory.

Ignition Developments

The most important factor in high-speed ignition is the time factor to energize the induction coil. To compensate for this, it is necessary to increase the flow of current or lower resistance in the primary circuit, and in doing this there is excessive sparking at low speed which oxidizes contacts and increases resistance, making it necessary to clean contacts at very short intervals somewhere varying from 1000 and 6000 miles. Duration of contact being very small due to the enormous number of sparks per second, agitated by oxidization, makes one set of contacts unsatisfactory when compared with the life of a well designed multi-cylinder, high-speed engine.

In view of this, therefore, around the beginning of 1915, my company started on three engines a continuous endurance run in order to see which part of the engine would wear out first. This endurance run was proposed to have a duration of 300 hours continuous running, and we found that it was impossible to run more than 13 hours at 2000 r.p.m. with the ordinary single arm breaker on the first type of eight-cylinder Cadillac engine. To overcome these serious objections, we built a distributer having two sets of contacts in parallel, or both closing and opening primary circuit simultaneously, each set carrying half the current, thereby reducing the arcing at the contacts to a minimum. Due to the tremendous inertia at high speeds, the contacts when closing are inclined to chatter, which causes the condenser to have a tendency to discharge, which in turn causes the arcing. This trouble is reduced to a minimum with two sets, as they do not chatter in synchronism and the adjustment of the two sets of contacts in parallel is not delicate, because in initial adjustment one set opens late and all arcing takes place on this one, causing it to waste away until it is in step with the one that opens first, so that they automatically come in step with each other. This arrangement makes it possible to operate an engine at a higher speed than any other arrangement at present developed, because it increases the time to build up the induction coil by decreasing the resistance.

After the above mentioned test, we were able to increase the speed of our engine up to 4000 r.p.m., which means 266 sparks per second, and after the installation of the two contacts in parallel, we were able to run 400 hours test without any ignition trouble, outside of occasional change in spark plugs.

(*Continued on page* 667)

What Is the Value of Rotation in Jobs?

Does Employer or Employee Benefit Most From Shifting Workers Frequently—or by Keeping Them Always at the Same Work?

By Harry Tipper

THE continual discussions which occur in regard to the increase of efficiency in production include, as a rule, statements concerning the necessity of increasing the efficiency of the human element, labor. It is not at all apparent from these discussions, however, that the same consideration has been given to the elements of human efficiency and the factors which must be taken into account in order to produce that.

It is true that a good many manufacturers have agitated for changes in the educational process in the schools and have instituted training schools in their own establishments for the purpose of securing a higher degree of skill from the workers, but these items merely indicate the general dissatisfaction with the present condition. They do not show that there has been any attempt to study the situation thoroughly, to make experiments in connection with it, in order to determine to what extent our present method of operation is based upon the proper conception of human interests, and to what extent it fails to take them into account.

The Human Element in Industry

The whole question of productive efficiency is concerned so intimately with that of education, the predisposition due to national tradition and social surroundings and political necessities, that it is hardly possible to consider efficiency from a manufacturing standpoint without, at least, understanding the deficiencies and tendencies of the rest of the worker's life. Even in respect to industrial surroundings it does not appear that we have studied the necessities of the case very seriously, and it is evident that we have concerned ourselves with the machine as the important factor in production, considering the human element as secondary and only to be regarded in order that the machine can fulfill its functions.

So long as we consider the human element secondary to mechanical equipment and only to be examined in relation to the machine, it is obvious that we shall not be able to determine the elements which enter into human efficiency from a productive standpoint correctly, and the discussions upon this matter must continue to be futile if not frivolous.

Specialization the Result of Factory System

In the growth of the factory system, with its machines constantly becoming more and more skillful and absorbing a larger proportion of the mechanical work of production, it was convenient to develop the worker for one particular piece of work. This method of operation required less supervision, that is, less intelligent supervision, and less preparation for manufacturing. It made it very much easier to train workers so that they arrived rapidly at a state of efficiency and it simplified the organization question. Some of these very advantages, however, were, in the nature of things, of negative value from the standpoint of human efficiency, and in some cases they were factors which actually reduced the capacity of the man.

Yet the system itself has not been questioned up to the present, and there is record of only one experiment in organization from a productive standpoint in an industry controlled by machinery. Discussion of the advisability of this system among engineers and manufacturers is fruitless, and this in itself is a symptom of the lack of study of the human element in production and, consequently, the almost total lack of understanding as to its requirements.

How do we know that one man, working on a gang of automatic screw machines for fifteen years, because his first training enabled him to be proficient in that work, can handle those machines to greater advantage than the man who has passed through a machine shop and knows the relative value of different machine operations and the relative proficiency required? How do we know that the skill of the fingers, and the co-ordination of the hand and the brain, are greater when the same operations must be performed by that co-ordination day in and day out for a number of years than where these operations are varied frequently.

The matter does not seem to have been discussed at all, but in view of the known variety of human interest, the known character of human aspirations and the recorded conditions of human production for the most part of its history, the practice is certainly open to question, and the assumed necessity a mere assumption of no greater value than that which attaches to a very brief tradition.

Psychology Shows Need of Variety

If the physiologist and the psychologist have secured any information in their scientific researches into the actions of the human body and mind, their determinations would indicate at least that such a method of productive organization was directly against the physiological and psychological requirements of growth and progress. To suppose that productive efficiency can be secured without the growth and progress of the individual worker, physically and mentally, is to indulge suppositions which are neither logical nor supported by practice.

Physiologists attempt to impress upon us continually that for good health and physical efficiency all the muscles of the body should be exercised reasonably, and that there should be a variety of exercise sufficient to take care of these necessities. The lack of balance—that is, the continual exercising of a few muscles and the neglect of others—is responsible for a great deal of the physical deterioration which has been observed among industrial peoples, particularly since the factory system has become so important.

The psychologist tells us that mental necessities are similar, except that they are far more important than physical necessities, because quickness of apprehension, understanding and mental sensitiveness, or the lack of

these qualities, influence the productive capacity, and also the point of view on all questions involved in social and economic life in an industrial country. The balance of mind and breadth of view are more important than any physical balance, necessary as that may be.

Some of the War's Lessons in Efficiency

During the war we have been taught some lessons upon efficiency in production which should indicate to us the necessity for fresh experimentation and for a deeper examination into our industrial organization, with the idea of discovering in what directions the present organization is weak and does not fulfill the requirements.

On the same machines with the same speed the incentive of patriotism expended in relation to the job improved production from 75 to 200 per cent in certain cases and improved it from 50 per cent in many other cases.

In the last few months a factory in England in the automotive field changed its procedure so that instead of holding a skilled mechanic to one job, his work is varied. The man who has been operating milling machines to-day may be assembling cars or motors next week, and contrary to all the traditional ideas upon this subject, this factory increased its production by three chassis a day with the same number of men, under the new system.

No man who has charge of supervision on any manufacturing work but has rebelled from time to time against the necessity of routine, the things which must be done each day in the same way. We strive to secure in all the other relations of life that variety which constantly keeps the intellect alive and quickens the apprehension by maintaining interest. Why, then, should it be supposed that there is greater efficiency to be secured by going contrary to this deep-seated human desire for variety of occupation and variety of interest?

Just because we accepted the tradition which began as a manufacturing convenience, and continued because there was no immediate problem to be faced, we have not thought it worth while to question the value of this tradition or to experiment with it to find out its necessity.

Routine Lessens Interest

The matter goes deeper than this, however, for where the routine has become so familiar that it has become subconscious, lack of interest follows as a logical consequence, and the possible efficiency is impaired by this lack of interest. Every manufacturer has noted the increase in productive capacity of the average individual under the stimulation of a new interest or the requirements of an emergency.

This productive capacity is not beyond ordinary possibility of the average human being, but there is no incentive to transfer to his regular work the energy which he has been willing to put forth under the stimulation secured from these causes. This extra effort, this unused or potential capacity, has shown itself of great importance during the war period, when it was stimulated into activity by the requirements of the war emergency and the demands of patriotism.

The question considered in this article is not provision of the incentive, which has been spoken about in previous articles and which relates to the responsibility of the worker in relation to the industrial organization of which he is a part, but it is a question of the reason for and the advisability of continuing the present type of industrial organization which trains a man for one piece of work and then keeps him at it continually without change.

The supposition that this method is necessary to secure the highest output per unit of cost is at present purely an assertion. No comparisons have been made with any other form of organization or with any other idea of production. It is not, however, in accordance with the known requirements of the individual in connection with his mental and physical growth, and it is not sufficient, therefore, to justify this organization by long and continued use nor to suppose it necessary because of the machine equipment.

It is obvious, of course, that the man who is working in a machine shop, running a milling machine, would be of no value running a loom. Neither would such a change increase his mental capacity in relation to his work. But there are good reasons for supposing the man who was grinding crankshafts to-day and fitting these crankshafts into the motor to-morrow, by grasping the importance of the previous piece of work and its relation to the motor efficiency, would be provided with an interest and an incentive in each piece of work that would not obtain to either by itself.

Whatever form of organization should be used from a production standpoint, it is obvious that the war has given us a glimmering of the importance of the human factor, that we are just beginning to understand the importance of the worker individually and as an organization, and it is being borne in on us that the present industrial system has not justified itself to the worker or to the general public.

This should encourage us to a new and deeper analysis of the human side of the case, to experimentation in production changes, especially those which involve the incentive and the interest of the worker, and above all, the rejection of all traditions and traditional forms of organization which cannot justify themselves except by tradition, so that we can either determine in how far they are valuable or sufficiently analyze them to be able to undertake changes that would make them valuable.

Make Them Property Owners

SOMEBODY has defined a Bolshevik as a man who has nothing and wants to divide it with everybody. Behind this more or less flippant definition there is an important germ of truth. A study of the records of what Bolsheviks we have known in this country, and those who have called themselves Bolsheviks or I.W.W.'s, or any other name which designates a more or less organized lawlessness, reveals the fact that very few if any own property.

When a man owns property he appreciates the necessity for well organized legislation, and for the necessity of enforcing laws. When the labor class as a whole in any community owns property, it is a law abiding and satisfied class. This is not only progressive in itself, but always carries with it a successful community.

Recent moves by great capitalists of the country to make the laboring man not only a profit sharer in the company in which he works, but also to make him an owner of property in the community in which he dwells, has met with marked success.

The dangerous element is always the floating element. As this is eliminated, stable conditions grow, and contentment reigns in place of discontent. The time has long gone by when large manufacturers and other employers of labor can merely satisfy themselves with paying the weekly wage and forgetting the general welfare of those who help to make their business a success.

The principles of profit sharing and of well organized and thoughtful welfare are becoming more and more firmly embedded in the minds of the executives of the country. No bigger step can be taken than to make the laboring man a property owner.

Radiator Cooling Fans*

Problems of Design and Mounting — Large Diameter vs. High-Speed Fans— Magnitude of the End Thrust on Fans — Means for Insuring Continued Dust-Proofness of Fan Hubs

By George W. Hoyt
Chief Engineer, The Oakes Co., Indianapolis

WHEN the subject of fans is investigated it is usually found that there is a great amount of doubt among engineers as to just what type, size and speed should be used for different motors. The decision should depend largely upon where the fan is to be used, whether on a passenger car, truck, tractor or stationary power unit. In connection with tractor fans, special attention should be given to dust-proofness of the bearings, and the packing retaining device should be adjustable. On passenger cars and trucks it is not so important to be able to adjust the pressure on the felt, though it is desirable there, too.

Most engineers will agree that the fan is given about as little attention as any part on the motor, until heating troubles appear. However, this condition is changing very fast. The first problem is to select a fan of the proper diameter and speed to work in connection with the other units of the cooling system. Too high a fan speed causes noise, while a fan that is too small will cause overheating. In the following, the various items of the cooling system are taken up in the order of their relative importance.

It is, of course, necessary to have the proper pump and radiator capacity to handle all of the water in the system and circulate it at an appropriate speed. After this has been settled, it is advisable to use the largest fan which will clear all radiator connections by at least ½ in., and will not overlap the upper or lower tank. If the fan's sweep were masked by the tanks, it would pull against a solid surface, which would decrease its efficiency.

Projected Area

After the diameter of the fan has been determined by the above mentioned method, the projected area of the fan or the blade path should be considered, which largely determines the air delivery. The projected area varies from 1½ in. up to 2¼ in. in accordance with the size of the motor to be cooled. Sometimes it is impossible to get a large diameter fan back of the radiator, and then the next best thing to do is to use as large a blade path as possible and still clear the fan belt by ⅜ in.

Referring to the drawings giving the capacity of different size fans, suppose that a certain volume of air is to be passed and it is found that an 18 in. fan with 1½ in. projected area, running at 1800 r.p.m. will give this air delivery. If you cannot get an 18 in. fan back of your radiator, you may step down to a 16 in. fan with a larger projected area, running it at the same speed as the 18 in. fan. Thus it is possible with a smaller diameter fan, by increasing the size of the projected area, to carry the same volume of air at a given speed. However, the best practice is to use large diameter fans and slow speeds wherever possible.

Size of Pulleys and Belts

After having determined the proper diameter and width of the fan blade, we next come to the width and diameter of the fan pulley. We have found by experiment that for fans up to 18 in. diameter, a belt 1¼ in. wide works very satisfactorily. In some cases, however, a manufacturer will drive the generator with the same belt, in which case a wider and heavier belt should be used. Fan diameters larger than above mentioned take belts up to 2½ in. in width. The proper belt width depends upon whether the fan is driven from a large or small pulley at high or low speed. Where the pulleys are small in diameter, and are run at fairly high speeds, a wide belt is necessary to avoid slippage. Sometimes it is not possible to get a large area of belt contact on the pulley, and a wide belt must then be used. It will always be found that, owing to the effect of weather conditions, water, oil and heat, the cost of a little extra belt width is money well spent. There is some doubt as to which is better, a crowned face pulley or a flat face pulley. This depends somewhat upon the width of belt. The flat pulley will work very well with a wide belt, that is, belts of such widths as mentioned above. However, tests made by us showed that a crowned face pulley is preferable, because it tends to keep the belt centered on the pul-

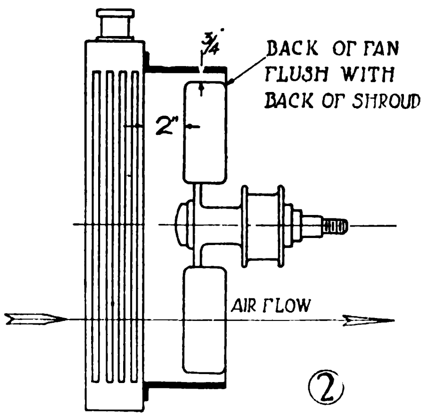
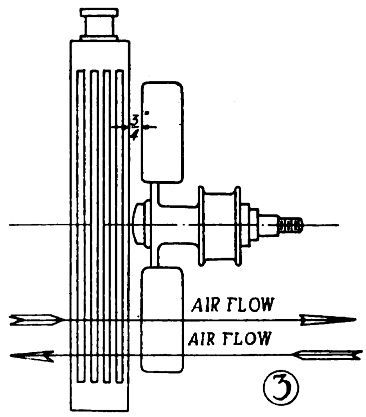
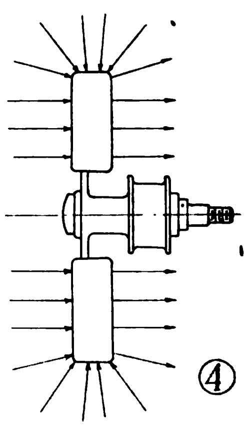
Location of fan in relation to radiator and shroud when blowing air



Location of fan in relation to radiator and shroud when drawing air



Location of fan in relation to radiator without shroud when blowing or drawing air



How a curved four-blade fan handles the air

ley, thereby getting the benefit of the full width of the belt. With flat, flanged pulleys, if the driven and driving pulleys are not absolutely lined up with each other, the edge of the belt tends to ride on the flange, which tends to decrease its pulling power. Another factor determining the necessary belt widths is the material of which the belt is made. Some belting material will stretch more than others, and cause slippage, and wide belts minimize this trouble. It all works out to this, that no matter how efficient the fan may be, if the belt is too small and there is slippage, the fan will be more or less of a failure.

Next it is necessary to determine the diameter of the fan pulley. This depends somewhat on the air delivery. Tests made in our laboratory, as well as by radiator manufacturers, have shown that for motors up to 50 hp. the air velocity through the radiator should be from 1500 to 1800 ft. p.m. depending upon the size of motor to be cooled. The pulley preferably should not be less than 2½ in. in diameter, as smaller pulleys are very apt to allow belt slippage, and decrease the fan speeds quite considerably. The fan speeds, of course, will vary, and in deciding upon this factor it should always be borne in mind that a large fan running at slow speed is the most efficient. This statement is corroborated by the volume curves and horsepower curves in Figs. 5, 6, 7 and 8. The fan pulley then must be of such diameter that, considering the diameter of the driving pulley and the speed of same, the fan will be rotated fast enough to carry the required volume of air, and the driving pulley should always be large enough to allow of a fan pulley diameter of at least 2½ in.

Fan Locations

We will next refer to the location of the fan. Some manufacturers use a fan shroud on the radiator, while others do not, and the proper location of the fan is very much affected thereby. Where a radiator is used without a fan shroud, the fan should be set with the front edge of the blades ¾ in. from the back of the radiator core, so that there will be a minimum loss. By referring to Fig. 4 it will be seen that when set farther away, the fan would pull the air from the top and sides of the hood, instead of through the corners of the radiator. This distance is also great enough to permit quiet operation, and allow for regular shop variations. This fan location, shown in Fig. 3, is satisfactory for blowing air as well as drawing air through the radiator without a fan shroud.

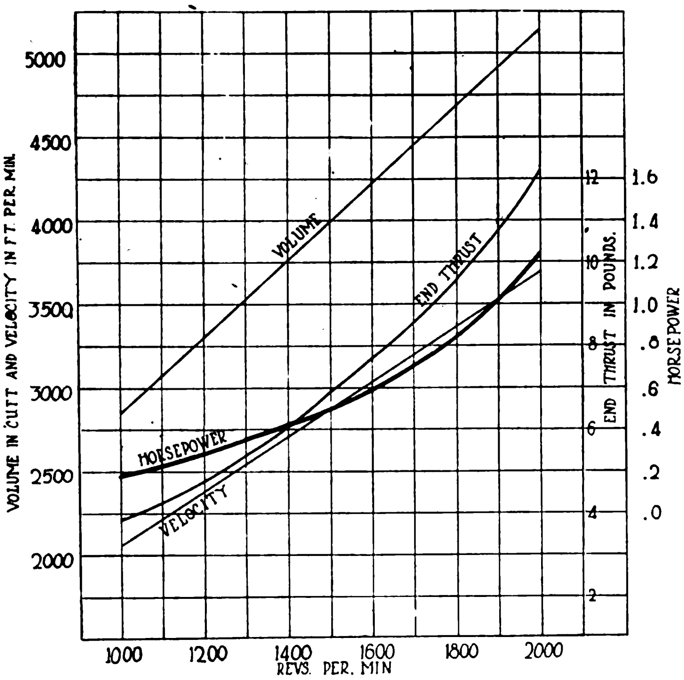


Fig. 6—Volume of free air handled, velocity of air, horsepower required to drive, and end thrust of an 18-in. diameter, 2¼ in. projected area, 4-blade pressed steel fan. Air tunnel diameter 16 in.

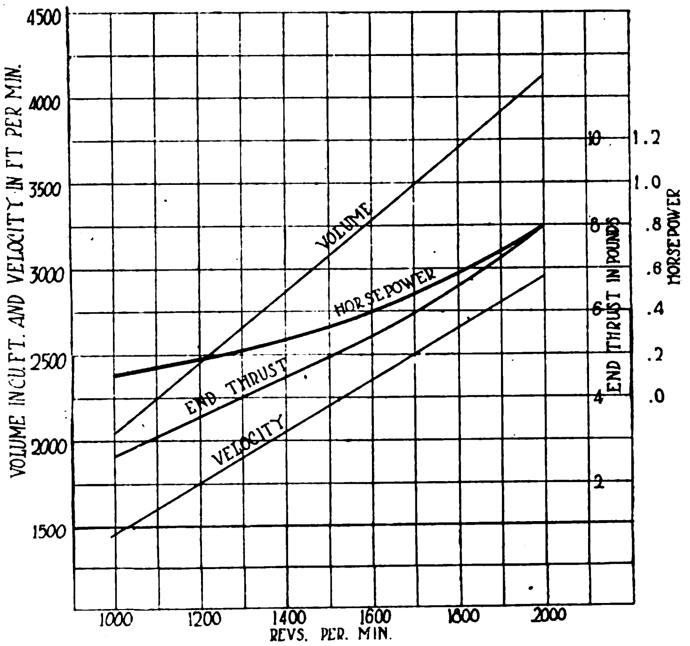

Fig. 5—Volume of free air handled, velocity of air, horsepower required to drive, and end thrust of a 16-in. diameter, 2¼ in. projected area, 4-blade pressed steel fan. Air tunnel diameter 16 in.

Fig. 2 shows the proper location of a fan when using a shroud and the air is drawn through the radiator. The front edge of the fan blades should be 2 in. away from the back of the radiator core, and the fan shroud should be so designed that its back edge will come flush with the back edge of the fan blades and that there will be about ¾ in. clearance between the shroud and the fan. If a fan is set closer than 2 in. to a radiator with shroud, it will be noisy, as with the fan operating in a shallow pocket the air gets no chance to spread and take a free course through the fan. Tests have shown that a fan located as shown in Fig. 2 gives very good results.

There should be a number of louvres in the side of the hood, of the proper size to allow the warm air to escape. Attention should also be given to the location of the floor boards and anything else that tends to increase the resistance against which the fan has to work, which parts should be so arranged as to allow the free escape of the warm air from under the hood.

Construction of the Shroud

The shroud should be made without sharp angles and corners, as these bank the air, holding it in the shroud and forcing it back through the corners of the radiator. This same effect is produced where a shroud overlaps the back of the fan blades, as it will not allow the air to get away from the fan. Quite often one-half of the blade width only is within the shroud, but this location is not the best, for the following reason: Fig. 4 shows that air is drawn in all around the end of the blade, and with the arrangement described half of the blade would draw warm air from under the hood, off the motor, and tend to keep this air circling around the end of the blade, thereby decreasing the true air delivery, as compared with the arrangement of Fig. 2.

When the radiator is in front of the motor the fan may be placed in front of the radiator. In this case the air should always be blown through the radiator, thus at the same time carrying the hot air off the motor. If the air were drawn through the radiator the hot air from around the engine would pass through and warm the water instead of cooling it. There is, however, one objection to placing a fan in front of the radiator, namely, that if not properly protected, the fan draws dirt and weeds that are lying loose in the field, and is apt to clog the radiator and interfere with its proper functioning. A front-mounted fan without shroud should be preferably located as shown in Fig. 3, with a view to forcing all the air possible through the radiator. Where it is neces-

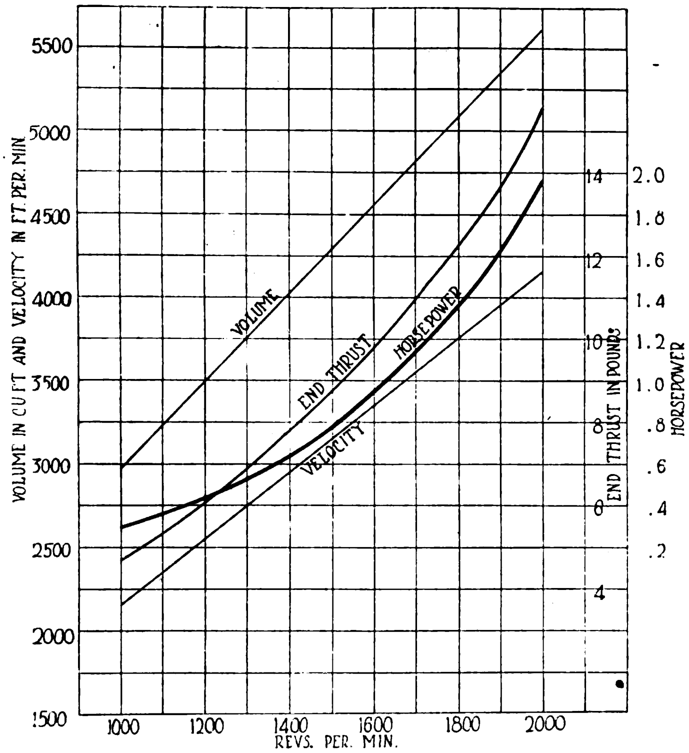

Fig. 7—Volume of free air handled, velocity of air, horsepower required to drive and end thrust of a 20-in. diameter, 2¼ in. projected area, 4-blade pressed steel fan. Air tunnel diameter, 16 in.

sary to use a shroud with the fan in front of the radiator, we have found it to be very good practice to locate the fan as shown in Fig. 1. The fan is located with the front edge ⅜ in. inside the shroud, to keep from spreading the air outside of the shroud, and at the same time leaving the largest portion of the blade out in the open air, in order to obtain the maximum amount of air. By locating the fan 1½ in. back from the radiator, enough space is left between the fan and radiator to spread the air so that it will pass through the corners of the radiator as well as the center.

For tractor purposes the use of a fan shroud is recommended, as great cooling capacity is necessary, and there is a gain of about 10 per cent from the use of a shroud, which is due to the fact that the air can be drawn through the corners as well as any other section of the radiator.

There is one other possible location of a radiator, viz., back of the motor and at the dash. In most cases it is necessary to place the fan back of the radiator, and drive it off the fly-wheel or propeller shaft, using the arrangements shown in Fig. 1 and 3, depending upon whether or not a fan shroud is used. The real objection to this fan location is that in most designs it is backed up so close by the toe boards that it is impossible to get the maximum efficiency out of the fan. However, the direction of air flow should be such that the warm air from the motor will not pass through the radiator.

In connection with the volume charts Fig. 5, 6, 7 and 8, it should be pointed out that in making the tests gasoline was used in the pitot tube and manometers. Both the static pressures and the velocity pressure were taken into consideration in reading the height of the gasoline column. The fans were driven by a 5-hp. motor and were located in an air tunnel tapered down to 16 in. diameter, the tunnel being 15 ft. long. The volume test was made at the same time. We are thus equipped to determine the end thrust of the fan and the horsepower consumed in driving it. The pitot tube is considered the most accurate means for determining air velocities and results obtained with it should not be compared with volume figures secured by the use of the anemometer, as the anemometer is only approximate for velocities as low as 1000 to 1500 ft. p.m., which with the average size fan corresponds to 800-1000 r.p.m.

We will now take up the choice of bearings, as the bearings are one of the most important parts. Quietness of operation, freeness of motion and the life of the fan all depend upon the type and quality of bearings used.

There are practically three types of bearings used for this purpose, namely, roller, annular, ball and cup and cone ball bearings. The latter is by far the most popular bearing for fan use, about 75 per cent of the fans on all of the trucks, tractors and passenger cars manufactured to-day being fitted with it.

Here some consideration should be given to the different loads on fan bearings. The radial load is due to the weight of the hub, blades, spider and all parts that revolve on the bearings, plus the tension of the fan belt necessary to secure a drive without belt slippage. In addition to this radial load, there is another load which is a very important factor. As the fan must draw or blow the air through the radiators, a great percentage of the load on its bearing becomes end thrust. In the past there has been a certain difference of opinion among engineers as to the amount of end thrust caused by different rates of air delivery. The end thrust depends upon three factors—the fan diameter, the projected area or the blade path, and the speed of the fan. A fan running in free air will produce a certain end thrust, but when this same fan is placed back of a radiator, between the radiator and the dash, and under a hood, the end thrust is increased about 25 per cent, depending upon the restriction of the air passage. The air will flow more easily through some radiators than through others, some motor hoods have better air outlets than others, but, in any case, there is plenty of end thrust, and this must be given serious thought.

We will now go back to the bearings. A straight roller

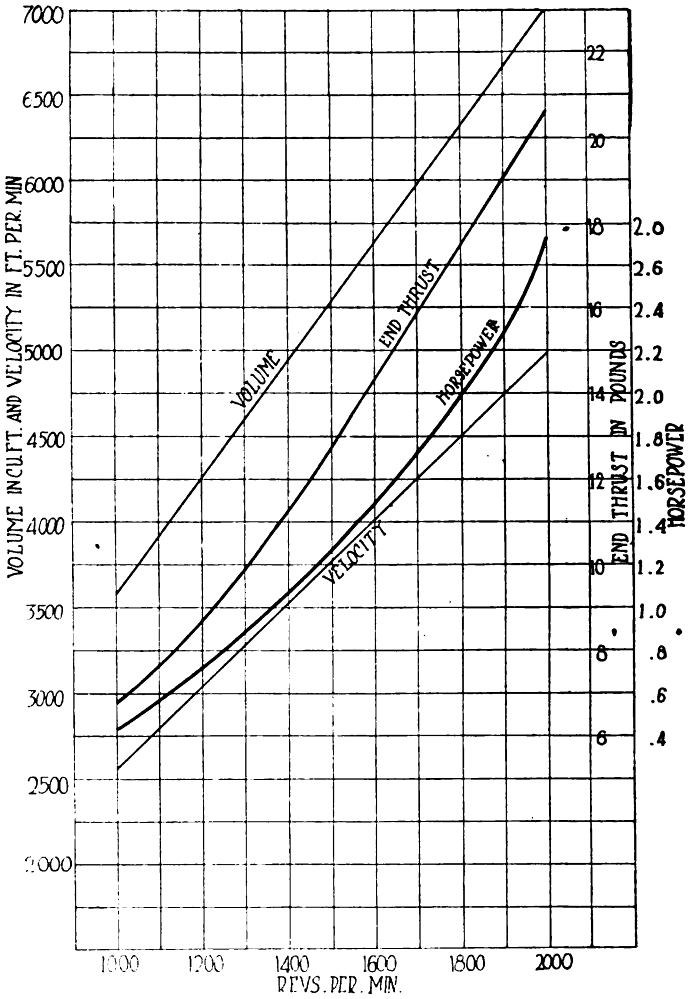

Fig. 8—Volume of free air handled, velocity of air, horsepower required to drive and end thrust of a 22-in. diameter, 2¼-in. projected area, 4-blade pressed steel fan. Air tunnel diameter, 16 in.

bearing designed to take radial loads only, when used with a hardened and ground outer sleeve and a hardened and ground spindle, will make a very satisfactory bearing for taking care of the radial load of the fan, but there must be some special arrangement made to take care of the end thrust. The amount of this end thrust is such that it should be taken care of by a ball thrust bearing. From Fig. 8 it can be seen that a 22 in. fan with 2¼ in. projected area, running 2000 r.p.m. and delivering 6890 cubic feet of air per minute through a 16 in. tunnel, will produce an end thrust of about 20 lb.

It can be safely said that not more than one out of every ten people driving cars ever oils the fan, and if a plain washer thrust bearing does not get oil, it will not be long before it gets loose enough to rattle. Ball thrusts, of course, also will wear out in time, but there is no question that there is not as much friction in the ball bearing as there is in the plain bearing, as the balls have only a line contact with the ball race, while the entire surfaces of plain thrust washers are rubbing together. I think I am safe in stating that there are very few engineers who have had experience with end thrust bearings who will not agree that the ball end thrust makes a higher grade construction.

As to the amount of end thrust, this can be found from Figs. 5, 6, 7 and 8 for different sized fans running at different speeds.

Referring to fans with annular bearings, this type does not need much of an introduction. When the proper size of bearing is used it will give satisfactory results, and carry both radial and thrust loads, but, of course, it must be kept properly oiled.

Next comes the cup and cone type bearing, and the popularity of this type is in itself proof of the efficiency of the bearing. The cup and cone type of bearing is adjustable both for radial load and for end thrust; when properly built and adjusted it will run longer under the abuse that a fan gets than any other type of fan bearing, with one possible exception, which is the annular bearing. These two bearings are very much alike, as far as carrying load is concerned, only that one is adjustable and the other is not. It is possible that the cup and cone bearing needs a rather delicate adjustment in order that it will work properly and be long-lived. However, this is true of any adjustable bearing, as, for instance, thrust bearings in the form of plain washers. These washers must not be clamped too tight, as they will then score and bind, and neither must they be too loose, as they will then rattle.

The one great secret of long-lived bearings is to make the hub as tight as possible, so that the oil can be kept in and the dust out. In order to do this, the hub must be designed to hold a good amount of oil or grease, and the felt washer retainers must be made adjustable so that oil can be kept in. A felt washer packing without adjustment will in time wear large around the shaft, and become oil-soaked to such an extent that it gets soft, when it is worse than no washer at all. With proper adjusting means the felt can be kept tight to the shaft, and the oil out of the felt, thereby making a much tighter fan hub. Why do we put adjustable felt washer retainers on our differential carriers on the rear axle, or on our front wheel bearings, or on our transmission bearings? We do it to keep the washers tight. There is the same need of a tight washer on a fan hub, which is the highest speed part of the motor.

The curves shown in Figs. 5, 6, 7 and 8 were drawn from tests made in the Oakes company laboratory and all except the end thrust figures were verified by the American Blower Co. of Detroit, which is recognized as an authority on fans.

The writer hopes that he has made clear the points which should be given special attention in order to lay out an efficient cooling system. He believes to have made it clear that any one unit cannot do all of the motor cooling, but all units must be designed to suit each other, and he would suggest that the manufacturers of trucks, tractors and passenger cars co-operate with the accessory manufacturers so that the latter can help solve the mechanical troubles met with.

Steam Power and Fuel Conservation

By Dr. C. P. Schwarz

REFERRING to your S. O. S. call for fuel economy, a handbook which I received while in London in 1914 states that a certain motor when operated on gasoline with specific gravity of 0.708 showed an efficiency of 27.5 per cent. The same motor when run on 0.745 gasoline showed an efficiency of 25 per cent. Evidently the constituents with a higher boiling point escaped—at least partly—without performing work. This would point to air-cooled engines.

Further economy could be effected by the use of smaller engines and 4-speed transmissions, less weight per unit of useful load, streamline bodies, etc.

It is perhaps not known generally that a steam engine working with steam at 600-700 lb. and having a proper valve gear has a theoretical efficiency of 28 per cent and even higher. It has been pointed out in a leading British engineering paper that 1 kilowatt has been produced with 8 lb. of steam in turbogenerators of no unusual size.

The well-known Swedish engineer, De Laval, constructed about 1894 a steam power plant which aimed in the direction of fuel economy; lack of funds stopped the development.

A properly designed steam plant, taking the thermal efficiency of the cycle at 28 per cent, the mechanical efficiency of the steam engine at 85 per cent and the thermal efficiency of boiler and furnace likewise at 85 per cent, would have a total efficiency of $28 \times 85 \times 85 = 20$ per cent or almost as great an efficiency as the average gasoline engine. (A Continental truck motor described in your paper 1919 shows 21 per cent.) But here is the rub: The efficiency of an internal combustion engine increases with the load, while a properly designed steam engine acts just the opposite. As most motor car power plants are over-engined they run a considerable time on part load and then their average efficiency is below 20 per cent, while the efficiency of the steam engine drops below the figure only on exceptional pulls.

As far as fuel is concerned the steam plant may be designed to take any fuel that will flow through pipes and contains a great deal of heat energy.

The comparison between gasoline and steam engines becomes very disadvantageous for the former if we look at it from a broader viewpoint, *i. e.*, from the conservation-of-natural-resources point of view.

From a Government publication on the Rittman cracking process I see that oil free from natural gasoline will produce about 50 per cent cracked gasoline, 25 per cent residual fuel oil and 25 per cent non-liquefiable gas. This gas is an absolute loss from a motive-power point of view, and there the efficiency of the gasoline engine, viewed from this broader standpoint, is $75 \times 21 = 15\frac{1}{2}$ per cent, or considerably less than for a steam engine, which uses the 100 per cent of the oil drilled.

From a strictly thermal point of view the possibilities of the steam car are not to be sneezed at.

Substitute for Manganese

IN a recent article in the *Pester Lloyd*, reference is made to a new process by which manganese is largely superseded in iron-founding, according to a method discovered years ago, but abandoned owing to the plenitude of manganese.

In its improved form the process effects a saving of 50 to 75 cents per ton, as compared with the calcium carbide substitute of the Thomas process, used by the German-Luxemburg Mining & Ironfounding Co. The method, which requires only 4.5 lb. of 30 per cent ferromanganese per ton of iron, has been evolved by the Hasper Iron & Steel Works, and the owners have placed their discovery at the disposal of the Union of German Ironfounders, so that all German iron works may be enabled to husband their manganese reserves to the utmost.

F-5-L Navy Flying Boat

Twin-Motored Tractor Biplane with Total Flying Weight of 7 Tons—Cruising Radius as a Fighter, 10½ Hours—Normal Crew Four Men

Part I

By S. T. Williams
Assistant Chief Engineer, Naval Aircraft Factory, Philadelphia

LITTLE has been said and less printed concerning aircraft development by the Navy during the World War —but much has been done. Seaplanes, rivalling the Handley-Page and Caproni in size and performance, have been quietly built in large quantities and have had no little part in subduing the submarine and keeping our domestic commerce safe.

Of these the F-5-L boat seaplane is distinctive. It is a twin-motored tractor biplane, having a total flying weight of nearly 7 tons, a cruising radius of 10½ hours as a fighter, or 8½ hours as a bomber. It carries a military load of over 1400 lb., with a crew of four men. This machine is a formidable engine in naval war craft, and it is so designed that it may be quickly and efficiently made under war conditions.

In the case of this machine the Navy, as did the Army, took a foreign design and modified it to meet American production methods. It is interesting to note, however, that in this particular case the English design had been based upon an American model, the large Curtiss flying boat—the H-12 which was the forerunner of both the H-16 and the F-5-L.

The F-5-L is a somewhat larger machine than either the H-12 or the H-16 and is capable of carrying a greater useful load. It was developed at Felixstowe, and the name "F-5" was chosen to denote the English experimental seaplane factory at Felixstowe ("F") and the model number design in machine ("5"). The Navy added the letter "L," indicating that, as built here, it is driven by Liberty engines.

The lines, overall dimensions and main constructional features were worked out in England and an experimental plane was constructed there. The details with many modifications were worked out at the Naval Aircraft Factory, Philadelphia, to correspond to its production methods. The planes were then put into production at that and other factories, such changes from the first drawings being made as were found necessary by tests.

Fundamentally the plane is similar to our American Curtiss flying boats—particularly the H-16 model. But in size and details it is quite different, being larger and better fitted to emergency production. For example, with few exceptions the fittings are soft sheet steel, cut from flat patterns and bent to shape.

This obviated the necessity of dies and drop forgings, which are particularly difficult to obtain under war conditions. The struts, likewise, are uniform sections, that is, not tapered, so that they can be shaped with a minimum of hand labor. Throughout, the parts are such that duplication is easy, production methods possible, and readily available equipment suitable.

The specifications herewith will give some idea of the size and capacity of this seaplane. It will be noted that the lift per square foot of surface is from 9.3 to 9.5 lb. per square foot and is somewhat greater than land practice.

The F-5-L is the latest development of the boat type seaplane, having the tail surfaces carried on the fuselage construction and the fuselage entering into the hull of the boat. The Curtiss boat seaplane may be considered a forerunner of this type. The characteristics are a fuselage similar to that of a land machine, planked in to form a boat body and having planes or steps similar to a hydroplane at the forward end.

Streamline of Boat Noteworthy

The most noticeable feature in the F-5-L is the degree to which the hull or boat has been streamlined. The hull cover sweeps aft, broken only by the cockpit openings. From an aerodynamic standpoint this is more efficient than the construction of the H-16, where a raised cabin is used.

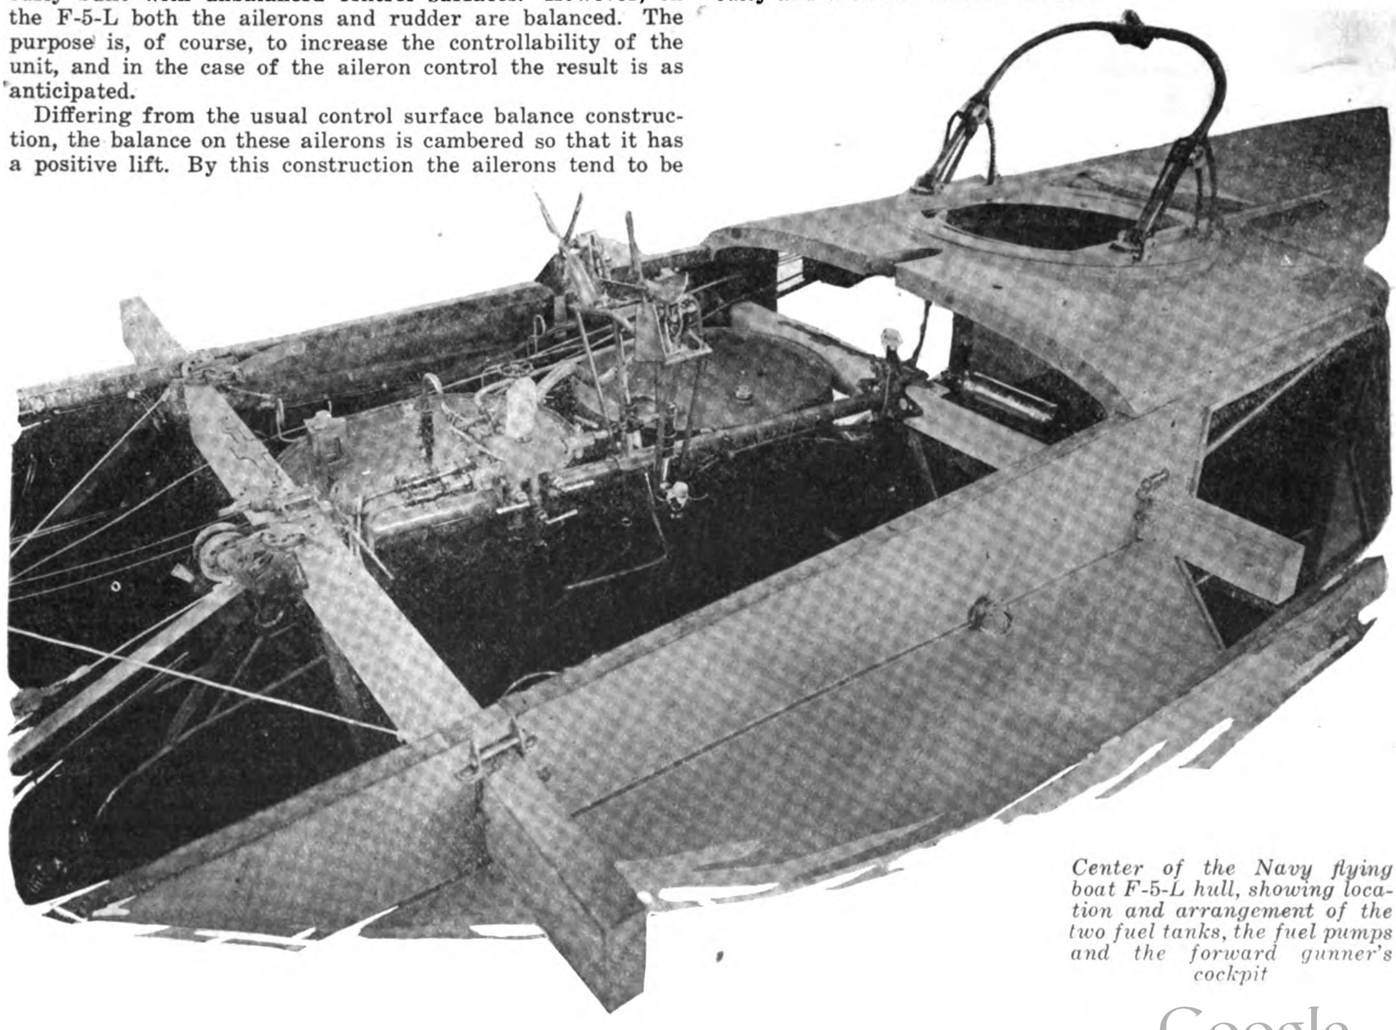
On this model, as on the H-16, the fin edges are continued aft and join into the lower longeron, giving a much stronger structure and better streamline form. Another feature in the hull construction that is noteworthy is the use of veneer instead of linen doped and painted on the after hull sides. It was found in practice that the linen failed in heavy seas or on a bad landing, but this failure was obviated by the use of veneer.

Specifications of Navy F-5-L Flying Boat

Overall upper wing (including ailerons)	103	ft.	9⅝	in.
Overall lower wing	74	ft.	4	in.
Overall length of boat	49	ft.	3¹¹⁄₁₆	in.
Overall height of boat	18	ft.	9¼	in.
Wing chord (H-12 curve)	8	ft.	....	
Gap between upper and lower panels C. L. beams	8	ft.	10½	in.
Angle of incidence of wings plus	3	deg.	40	min.
Dihedral of wing	1½	deg.	....	
Stagger of wings	None		....	
Angle of incidence horizontal stab. plus	2½	deg.	....	
Engine sect. panel	108	sq. ft.	....	
Interm. and upper outer panels (311 sq. ft. each)	622	sq. ft.	....	
Ailerons (59 sq. ft. each)	118	sq. ft.	....	
Sidewalks (33 sq. ft. each)	66	sq. ft.	....	
Lower wings (240 sq. ft. each)	480	sq. ft.	....	
Non-skid planes (15 sq. ft. each)	30	sq. ft.	....	
Horizontal stabilizer	121	sq. ft.	....	
Vertical stabilizer	35	sq. ft.	....	
Elevators (28 sq. ft. each)	56	sq. ft.	....	
Rudder	33	sq. ft.	....	
Total lift surfaces (including ailerons)	1394	sq. ft.	....	
Hull length	45	ft.	3¹¹⁄₁₆	in.
Hull width	10	ft.	....	
Hull height	6	ft.	1¼	in.
Pontoon length	7	ft.	....	
Pontoon width	..		20	in.
Pontoon height	..		35¾	in.
Power plant	2 Liberties			
Propellers (subject to change), 2-blade	10½	ft.	6¼	ft. pitch

With few exceptions, all large seaplanes have been previously built with unbalanced control surfaces. However, on the F-5-L both the ailerons and rudder are balanced. The purpose is, of course, to increase the controllability of the unit, and in the case of the aileron control the result is as anticipated.

Differing from the usual control surface balance construction, the balance on these ailerons is cambered so that it has a positive lift. By this construction the ailerons tend to be more sensitive in their action and to operate with less difficulty and with less balance surface.



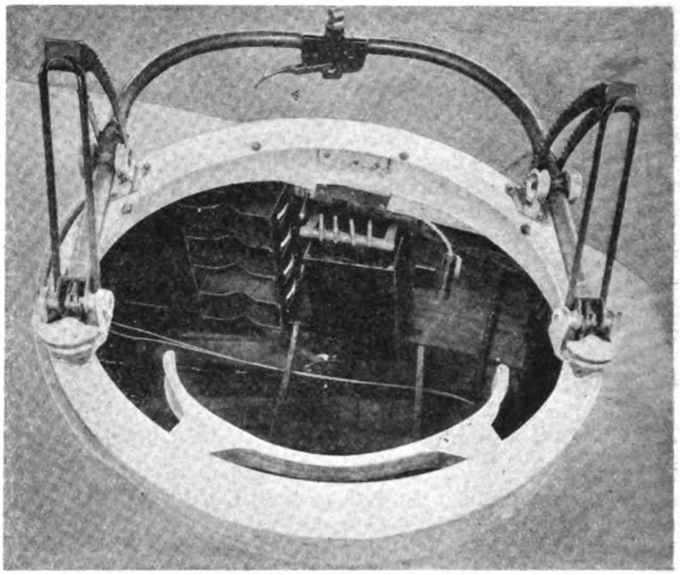
Center of the Navy flying boat F-5-L hull, showing location and arrangement of the two fuel tanks, the fuel pumps and the forward gunner's cockpit

The planing action is increased by the use of vents extending through the hull aft of the rear steps, similar to the vents that are used on the pontoons of the R-6 Curtiss model. It was stated that the hull swept aft in a perfect streamline, and the cabin top over the pilot's cockpit was eliminated. However, a certain amount of protection is afforded the pilot by small adjustable windshields.

Due to the fact that the pilot's head is about on a level with the hull cover, this serves to divert the air currents and protect the pilot with a minimum of air resistance. On straight flying it is possible to pilot the machine without the use of goggles, though caution demands their use.

Function of Seaplane

It might be well here to outline briefly the function of this seaplane, that the arrangement of the parts to carry out the duties of the plane may be described. Its chief use is patrol duty over harbors and main lines of ocean travel. Air stations are established along the coast and from these patrols are sent out at regular intervals, each going over a definite area, watching for submarines and possibly convoying transports or freighters. The machines are equipped with bombs and machine guns, the former being used on submarines and the latter on hostile aircraft and water craft on the surface. Special duties such as bombing an enemy harbor or city emergency calls to submarines discovered by other aircraft or water craft require an armament not much different from the above.



Forward gunner's cockpit on the F-5-L Navy flying boat, showing arrangement of gun mount and ammunition racks

A patrol crew usually comprises four men, the pilot, two mechanics and an observer. The observer has many duties—to watch for submarines, drop bombs, man the front machine gun, act as assistant pilot, and possibly be wireless operator. The pilot's duty is to direct the machine and he is first in command. The function of the crew is to handle the gasoline distribution, care for the engines, and man the aft machine guns in any fight that may occur. It is also their duty to have all parts of the machine under continuous inspection during flight and notify the pilot if any part is wrong.

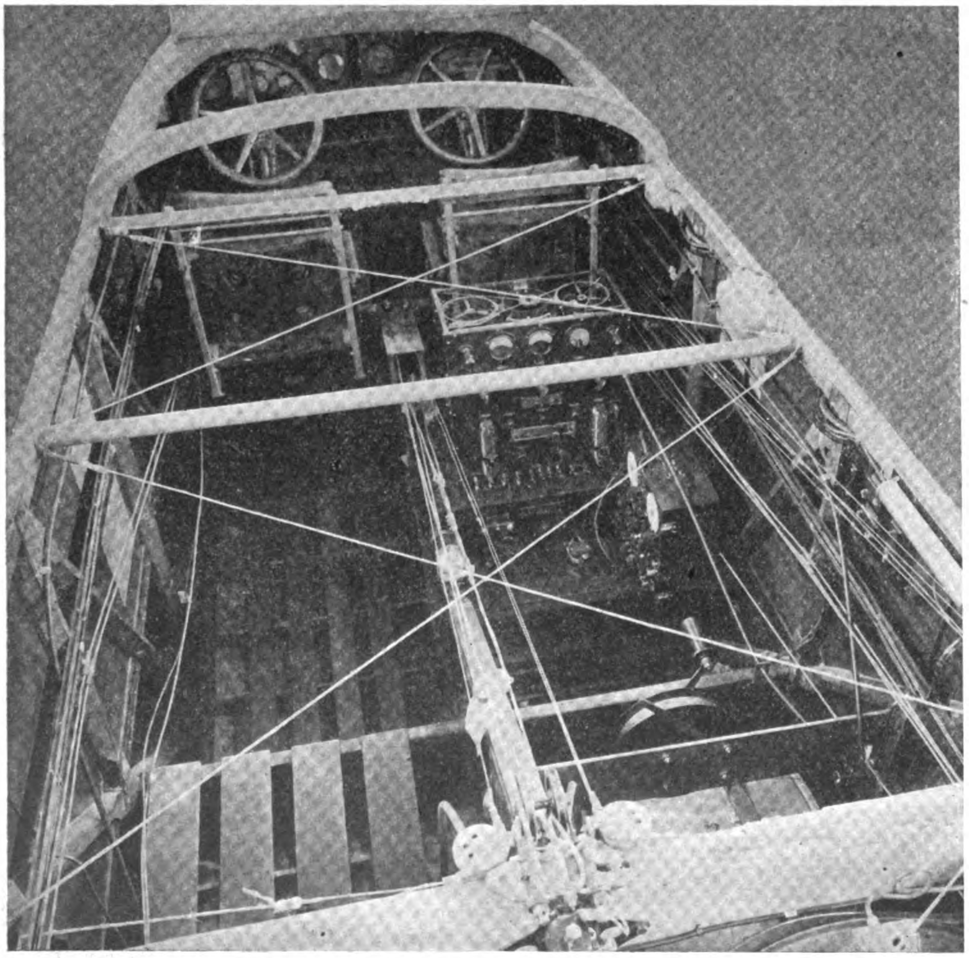
The whole layout of the machine is such that these duties may be most readily carried out. The observer's cockpit is in the nose of the machine and from it the widest range of vision is possible. At the bow is mounted the bomb sight and adjacent to it are the bomb release pulls, ammunition racks, signal pistols, binoculars, etc. A machine gun turret is mounted on the scarf-ring of the forward cockpit, so that the observer may aid in repelling aircraft attacks or, if necessary, sweep the deck of the submarine with machine gun fire.

The pilot's cockpit is just aft the observer's cockpit, and may be readily reached from it when the machine is in operation. The pilots are seated on comfortable seats, hinged on a bulkhead and attached to a transverse tube by means of a snap catch that may be instantly released. This permits the observer to pass aft at will without disturbing the pilot.

A wheel control of the dual type is used. It comprises a laminated ash yoke on which are mounted the two aileron wheels connected by an endless chain. An instrument board containing tachometers, altimeters, air speed indicator, oil pressure indicators, inclinometer, and pilot-directing bomb sight is mounted directly in front of the pilot.

On the starboard side of the hull are the individual engine switches, ammeters and emergency switches, together with the circuit breakers. The two compasses are mounted at some distance apart, so that they cannot interfere with each other. One is on the deck and the other on the floor. All instruments are self-luminous, but instrument board lights are provided.

The spark controls are at the



Looking into the F-5-L hull at the twin pilot's seats and the wireless operator's quarters and equipment

starboard side of the starboard pilot's seat, but the throttle controls are between the two pilots, so that either may operate them. Fire extinguishers are placed convenitnely at each station, those in the pilot's cockpit being attached to the bulkhead beneath the seat.

The wireless operator's station is on the starboard side just aft the pilots. The equipment is mounted on a small veneer table, and used in conjunction with a telescopic mast that is carried in the stern. A celluloid window in the hull side provides necessary light.

Mechanics Stationed Amidship

The mechanics' station is amidships by the gasoline tanks and pumps, and their main duty is to see that the plane is "trimmed" by pumping gasoline from the tanks alternately; to see that the engines do not overheat, and that all parts function properly. The water and oil thermometer are mounted on the sidewalk beam adjacent to the mechanics' station.

Aft the mechanics' station, or wing section, is the rear gunner's cockpit. Three guns are accessible from this station, and it also provides a good point of observation or position for aerial photography.

All machines are equipped with inter-communicating telephones, the receivers being incorporated in the helmets and connection effected by terminal boxes at each station. It is thus possible for all members of the crew to be in constant communication.

Voluminous Equipment Carried

In addition to the equipment indicated, the following are some of the miscellaneous items usually carried: Tool kits, water buckets, range and running lights, pigeons, emergency rations, drinking water, medicine chest, sea anchor, chart board, mud anchor, anchor rope, heaving lines, signal lamp, binoculars, Verys pistol, ammunition, life jackets, and possibly electric warmers. Included also are the priming cans, drinking cups and usually several personal items. All this is exclusive of the ordnance equipment of bombs, machine guns, etc.

Considering the size of the machine and the amount of material carried, the performance is quite remarkable. In fact, it compares very favorably with the performance of land planes having the same specifications and not hampered by the heavy boat construction.

The time required to get the machine from the water varies with the wind velocity, but with a 15-mile wind and the plane fully loaded, from 30 to 40 sec. is required. The speed at take-off is about 47 knots on the air speed indicator, and a machine of this design has made a climb of 4200 ft. in 10 min.

Horizontal Speed 85 to 90 M.P.H.

A horizontal speed of from 85 to 90 m.p.h. is attained, but on patrol duty they are generally flown at a more economical speed, such as 70 m.p.h. When geared Libertys were tried out in one of these machines a speed of 102 m.p.h. was attained, but this was a special power plant equipment.

The engine revolutions are about 1500, though this, of course, varies with the types of propeller used. At full speed the gasoline consumption is about 65 gal. per hour and the oil consumption about 2.6 gal. per hour. By throttling down the engine to 1350 r.p.m., or to a speed of about 60 knots, the gasoline consumption per hour is reduced to 44 gal., the oil consumption remaining the same.

Maximum Cruising Radius 10.6 Hours

This gives a maximum cruising time of 10.6 hours with a light machine or 8½ hours fully loaded. The cruising time at full speed is 7.3 hours and 5.9 hours respectively.

The advantages of operating at cruising speed are many and it is at this speed that the plane is chiefly operated. Among the advantages are increased engine life, greater ease of control, longer cruising radius, less strain on plane parts, and time for more extended observation.

When running at full speed, control is not particularly easy, though under normal conditions one pilot can operate the machine without difficulty. However, the reserve control is necessary to lift the machine from the water, and in cases of emergency, though not ordinarily used.

(To be continued)

When Motor Trucks Saved Verdun

First Complete Description of the Motor Truck in the Greatest Battle of the Greatest War

By W. F. Bradley

THE story of how automobile trucks saved Verdun, and doubtless changed the whole face of the war, was first told in AUTOMOTIVE INDUSTRIES; but when this story was published the war was in progress and the French military authorities objected to the publication of figures and details. Now these restrictions have been removed, and Paul Heuzé in an interesting article in the *Revue des Deux Mondes* gives, for the first time, important statistics on this operation.

> **Motor Vehicles at Verdun**
>
> Hauled 2,000,000 tons of materials.
>
> Moved 2000 tons of ammunition daily.
>
> Transported 100 tons of food and other supplies to 20 divisions each day, a total of 2100 tons.
>
> Carried 15,000 men to and from front lines each 24 hours.
>
> Removed supplies from Verdun to prevent possible capture by the enemy.
>
> Operated over a 22 ft. road 45 miles long.
>
> Passed a given point on the highway at an average of one vehicle each 14 seconds.

During the year 1915 the French Automobile Service had been fully developed on its present and most satisfactory lines. One month after the outbreak of the war the French army possessed between 9000 and 10,000 trucks, of which 6000 were approved army types. The battle of the Marne showed that this number was totally insufficient.

During the whole of 1915 the French Automobile Service purchased trucks which were available in France, America and in Italy. During the whole of 1915 the development continued on well defined lines. Trucks were grouped into sections comprising 17 or 18 vehicles, together with a rolling workshop which was sometimes a truck and sometimes a trailer. Four of these sections united formed a group of 70 to 80 trucks under the control of a captain, and having a capacity for moving one infantry battalion or for carrying one day's supply of food for an army corps of two divisions.

These groups formed a tactical unit of the automobile service. After the groups had been formed, it was found necessary to unite these in companies of six, which were termed "groupments." These groupments had a capacity for transporting one brigade, which is the highest purely infantry unit.

Reserve Groupments

These sections, groups and groupments, consisting respectively of 18, 72 and 432 trucks, were attached to their respective armies and carried out the regular daily work of these armies. The idea had been developed, however, of forming reserve groupments which would be at the disposal of the General in Chief and used for whatever work he might indicate. This move had been rendered necessary by the fact that the army had found it important to provide for rapid movements of troops by means of automobiles. As the groups and groupments had their regular daily work with the army, they could not be relied upon for bigger movements of troops; hence, the formation of the reserve groupments, each groupment consisting of from 1200 to 1500 vehicles.

All this organization had been completed when, at 7.15 a. m., Feb. 21, 1915, the German army launched what has been described as the greatest battle of the greatest war. For 9 hours 2000 German guns shot several million shells of all kinds into the French front lines. Under such a deluge of shrapnel, high explosive, asphyxiating and tear shells, the French lines were flattened and the troops obliged to retreat. The German attack was skilfully organized, for the French line of supply was limited to one single-track railroad, having a capacity for not more than 2000 tons per day. When this line was cut—and naturally the first object of the German headquarters was to cut this line—the French had no other source of supply than the road; but, even here, the French were in a disadvantageous position, for, from Bar-le-Duc to Verdun, there was and still is but one road, and this only a fourth-class road just wide enough for three vehicles to run abreast.

As soon as it was realized that this was no ordinary local attack, orders were given to the automobile service to prepare to supply the Verdun armies with everything necessary to hold back the German invasion. This was the first occasion in the war, or in any war, on which an army had to rely exclusively on automobiles for its supplies. The task was as follows: to deliver from the railhead at Bar-le-Duc to the region of Verdun an average of 2000 tons of ammunition per day; to transport daily 100 tons of food and varied supplies for 20 divisions, making a total of 2100 tons; to carry up to Verdun, or bring back, from 15,000 to 20,000 men per day; to undertake the removal of supplies and varied army material which were then in Verdun and in danger of being captured by the enemy.

Roads Limiting Factor of Truck Efficiency

As already explained, the automobile service at this time was perfectly organized. The weakest point was the road and road regulations. Truck trains worked satisfactorily, but their limiting factor in very many cases was the road. This had been realized, and just before the Verdun battle developed a scheme had been completed, on paper, to get a maximum efficiency out of the road.

This scheme went into effect in the beginning of the Verdun battle. The 45 miles of road from Bar-le-Duc to Verdun was given over to automobile traffic exclusively. No horse or horse vehicle was allowed on this road under any circumstances. The stretch of road was split up into six zones or "cantons," which were organized in the same way as a railroad. An officer with a squadron of traffic police was made responsible for each zone. He had telephonic communications with posts placed along his road, and also with the chief of the other zones. He had orders to keep traffic moving at a regular rate. No vehicle was allowed to stop. If one broke down and could not be moved within five minutes, it was dragged off the road or even turned over into the ditch so that there should be no block in the traffic. The loss of a vehicle or even of a score of vehicles was a matter of minute importance when the safety of France and of the entire world was at stake.

It was during this time that an improvement, very slight in itself, but destined to have wonderful importance, was adopted. The trucks were split up into sections of not more

than nine and the last truck of each section carried a big red disk. No driver was allowed to approach to less than 100 yards of a red disk. By this means the trucks flowed along the road regularly in groups of nine with equally regular gaps of 100 yards between them. These gaps were made use of by touring cars which could pull into the openings thus formed and retain their positions until road conditions made it possible for them to move ahead.

The traffic on this 22-foot road was intense and continued day and night. Official papers show that 6,000 trucks passed a given point in 24 hours, this being an average of one vehicle every 14 seconds. At certain times of the day, and sometimes for several consecutive hours, there was a truck every five seconds. There were on this road more than 9000 automobiles, comprising about 3500 trucks, 2000 staff cars, 800 ambulances and about 200 meat-carrying trucks. In addition to these, there were various special automobiles belonging to the Engineering, Artillery, Air Service, Balloon Corps, Camouflage Sections, Telegraphic, Wireless, Photography, and others.

By the month of June the number of vehicles in use on this road had increased to 11,500. These automobiles carried an average of 9000 men and 15,000 tons of supplies every week. They totaled nearly 1,000,000 miles every seven days, or more than 25 times the circumference of the earth. The total tonnage carried by automobiles during the Verdun battle is rather difficult to estimate, for it comprised supplies, valid troops and wounded, frequently all mixed up, but the total is certainly not less than 2,000,000 tons. If the whole of this material were united it would cover an area of 12,000 sq. yd. and attain a height of 650 ft.

When the automobile service undertook to supply the Verdun army with everything it needed, the stipulation was made, first of all, that no horse should be allowed on this road. At that time, this seemed a very small matter, but there is no doubt that but for this stipulation the road service would have broken down, and as a consequence Verdun would have been lost. They also stipulated that the truck trains should carry their loads right through to destination instead of transferring them to horse-drawn vehicles for final distribution, as had been the custom in the French army up to that time. They insisted on authority being given them to organize the road in accordance with their own plan, and they claimed all necessary facilities in order to keep the road surface in condition.

Road Maintenance

One of the most difficult problems was the maintenance of the road. Within 48 hours of this automobile service being organized, large numbers of territorial troops were sent up for the sole purpose of road work. The number of men working at any time was generally about 1200. In ten months these men put on the road 700,000 tons of stone. The absolute necessity of keeping the traffic flowing steadily at all times made it impossible to use steam rollers. The road menders threw the stones down wherever necessary and the automobiles had to roll in this stone. Their orders were to keep the road in good condition but never, under any circumstances, to stop the flow of traffic.

In addition to this, along the roadside little refuges were established and stones brought to these and kept in readiness for placing on the road itself. The task of the road makers was hard. They had to work throughout the severe winter, to remain on the job in all weathers and had to throw in a shovelful of stones whenever there was a gap between two vehicles. Accidents happened at times, but it was the price that the road menders had to pay in the great struggle against the Kronprinz's forces.

Running day and night, without lights, over a rough road frequently shelled by the enemy, with drivers who had to remain on duty from 24 to 75 consecutive hours, it was not surprising that the automobiles soon began to show signs of breakdown. Tire usage was so rapid that at Bar-le-Duc children made a practice of gathering from the road chunks of rubber which had fallen or which had been torn off the tires of the trucks, and sold these at a penny a pound.

To overcome the difficulty, six hydraulic presses were installed at a convenient point behind the lines and were operated day and night, during the whole of the Verdun battle. Although tires were first to show signs of wear, it was not long before mechanical difficulties developed. The drivers had not time to lubricate chassis accessories frequently; all they could do was to add to the supply of oil in the base-chamber. It was impossible to change the oil. There was frequently no time to stop and add water to the radiator. If an engine ran hot, it had to be forced along until a period of calm made it possible to supply more water.

Under such conditions, defects soon began to develop. To make matters worse, the supply of spare parts for American trucks, large numbers of which were used in the Verdun battle, was stopped at this time. To meet this efficiently, the Automobile Park at Troyes had to arrange to manufacture parts for trucks.

On an average the total losses were 3 per cent per month. When the battle began, a repairshop was in operation in the city of Verdun. This was removed under very great difficulties and sent back to Ligny-en-Bellois, where it operated in conjunction with the main repair park, at Bar-le-Duc. In this park were 30 5-ton breakdown trucks, each one of which had two gangs of mechanics. Whenever an automobile was reported as broken down on the Verdun road, one of these trucks was sent out in order to repair it or, if necessary, to tow it home. This was dangerous work, for many of the trucks were broken down by reason of the enemy's action, and not a few of the mechanics who went out to bring in broken trucks paid for their devotion with their lives.

Truck Removing Service

Soon after the automobile service at Verdun had been efficiently organized, an attempt was made to save as much material as possible from the city of Verdun. When the attack began there were more than 6000 civilians in this town. With the city under shellfire and in danger of being captured by the enemy, these people were obliged to move away, but, at first, no vehicles of any kind were available, and it was on foot, carrying with them very meager baggage, that the old men and women and children abandoned their homes.

During the critical period, between Feb. 25 and March 8, a small number of trucks went into the town and removed important documents from the City Hall. By the end of the first week in March, there were not more than two or three civilians in the entire city. After the month of March, a regular truck removing service was organized. Fifteen trucks were turned over for this work, together with a company of soldiers who, in civilian life, had been professional removers. These men went into the city every day and removed furniture, machinery and other valuable material from Verdun to the railroad stations at Bar-le-Duc or other points. This work went on throughout the summer, and by the month of October everything which was worth saving and had not previously been destroyed by the German bombardment had been moved out of the city.

How many men of the automobile service lost their lives in the Verdun battle is not known. The number, however, is considerable, for the trucks took their supplies right up to the batteries and the drivers of ambulances went practically to the first line trenches under cover of darkness. This service had been carefully organized; drivers knew which roads were open to them and which roads could only be used at night time, or during daylight hours by vehicles running singly and at speed. Signs placed along the road showed where truck trains should stop, where vehicles should go through one by one, and where all traffic should stop during daylight hours.

The Altitude Laboratory—Correction

REFERRING to the article on the Altitude Engine Test Laboratory which appeared in the March 6 issue of AUTOMOTIVE INDUSTRIES, by the omission of several words from the sub-head a rather misleading sense was imparted thereto. The sub-head should have read: "Installed at the Bureau of Standards for the National Advisory Committee for Aeronautics."

Bureau of Standards Carbureter Test Plant

Designed to Determine Metering Qualities of Different Carbureters Under Varying Conditions of Atmospheric Pressure and Pressure Drop —Pulsating Suction Without Running Engine

By P. M. Heldt

ONE of the test plants built at the Bureau of Standards at the request of and in co-operation with the National Advisory Committee for Aeronautics for the immediate purpose of development work in connection with the Liberty and other airplane engines was designed for making carbureter tests. The object of this plant is to determine the metering qualities of a carbureter under different conditions of temperature, pressure drop and intake pressure, and to do so without having to make engine tests at the same time.

Tests can be made not only at atmospheric pressure, but at pressures as low as one-quarter atmosphere. The importance of this will be realized when it is stated that a reduction in atmospheric density has a powerful effect on the metering qualities, a reduction of 50 per cent in the atmospheric pressure ordinarily entailing an enrichment of the fuel mixture of about 45 per cent.

It must be considered that an engine of the size of the Liberty consumes from 30 to 35 gallons of gasoline per hour, and, counting depreciation of the engine and other expense items, it will be appreciated that a carbureter test with the instrument fitted to an engine involves a great deal of expense. As tests had to be made on different designs of carbureters under numerous different conditions, it was believed that a good deal of expense could be saved and at the same time a setup arranged for that would greatly facilitate the tests by installing a special carbureter test plant. Of course, it is realized that no test is so dependable as one carried out under actual service conditions, and it is admitted that the results obtained generally require checking by a test on an engine in operation, but such a check run is much less onerous than the complete test would be.

THIS is the fifth of a series of articles prepared by Mr. Heldt from the research records of the Bureau of Standards in Washington. Previous articles have covered:

1—*Dry Cell and Storage Batteries*

2—*Tests of Airplane Radiators*

3—*Altitude Engine Test Laboratory*

4—*Tests of Ignition Apparatus*

Additional articles covering other subjects will appear in subsequent issues.—EDITOR.

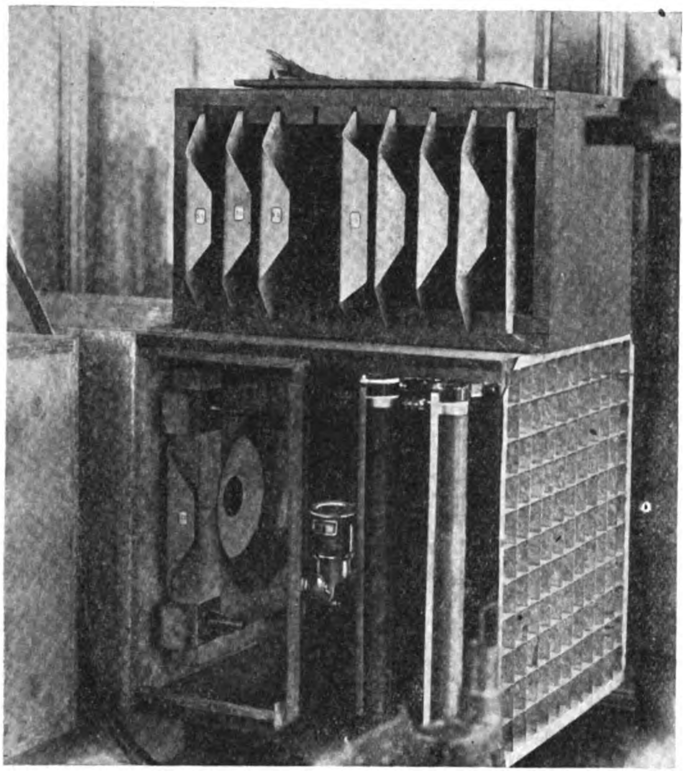
Engine Conditions Closely Approached

Most laboratory metering tests that have been conducted in the past, including the well-known series by Rummel some 10 years ago, were made under the condition of a steady suction. While it is generally believed that the results obtained under these conditions permit of valid conclusions being drawn regarding the action of a carbureter under the influence of the pulsating suction of an engine, it is certainly desirable that the suction effect of an engine should be reproduced as closely as possible in a laboratory test, and this is done in the Bureau of Standards carbureter metering test. The tests can be conducted under air intake pressures as low as one-third atmosphere, and the apparatus is arranged in such a convenient manner that one person can control the test and take all observations. As in an aircraft engine the air is generally heated before entering the carbureter, means are provided in the test plant equipment to raise the temperature of the air above atmospheric temperature to any desired degree. These take the form of electric heating grids in the air passage. The apparatus used comprises the following: An air meter, a throttle valve, an air heater, the carbureter chamber, a pulsator, an air pump, a fuel meter and pressure gage columns.

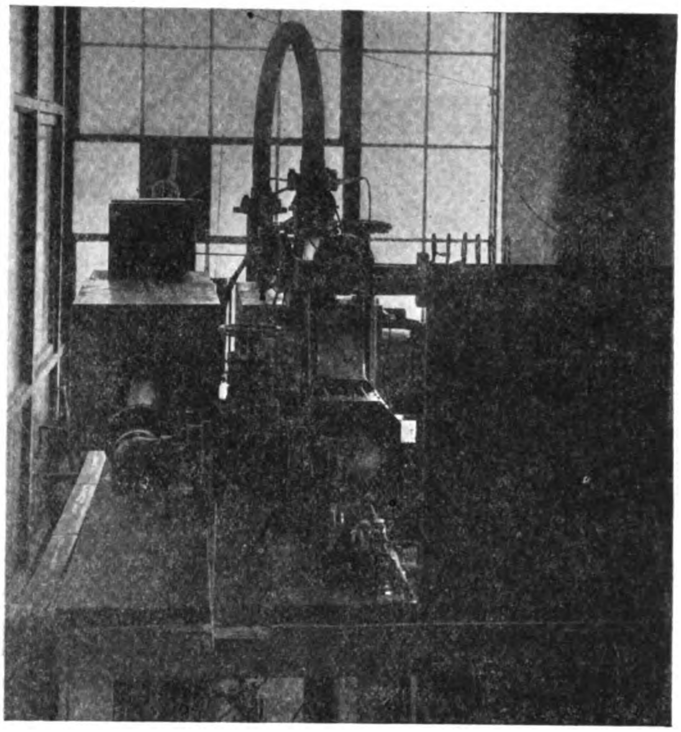
The air first passes through the air meter, then through the throttle valve, over the heating grids into the carbureter chamber, where it enters the carbureter under test. From the carbureter it passes through the pulsator to the blower pump, from which it is discharged into the atmosphere.

The air meter used is of a type first described by R. J. Durley in the *Transactions* of the American Society of Mechanical Engineers and is based on the flow of air through orifices in thin plates. One change that has been made from the Durley arrangement is that the direction of the flow is into instead of out of the chamber. With certain precautions taken in the tests, this has no effect on the accuracy of the measurements.

Means are also provided for protecting the air current as it enters the orifice from disturbance by stray currents in the room, the orifice being provided with an approach passage with a protecting grid. The orifices are bored in steel plates 0.057 in. thick, ranging in size from 3.5 to 0.5 in., by 0.5-in. decrements, with absolutely square edges. In addition there is a 5/16-in. orifice, and a blank plate is used for checking the tightness of the chamber and throttling valve. Rectangular gaskets of pure gum rubber ¼ in. thick form seatings for the orifice plates and insure absolute airtightness even though the plates may be sprung out of shape.

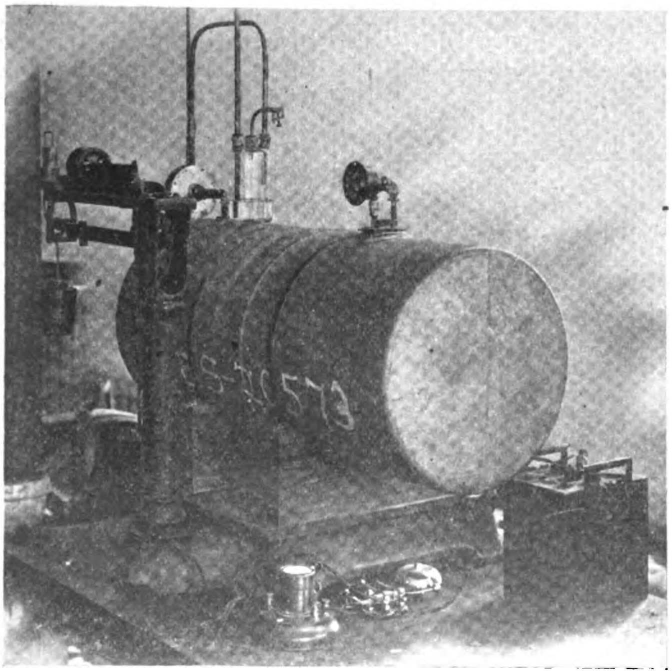


This illustration shows, on top, the set of Durley orifice plates and, below, the air meter. On the side of the air meter box are mounted the rate-of-pulsation indicator and field rheostats for the electric motor



End view of the carbureter test installation showing the air meter at the left, the carbureter test chamber in the center and the back of the manometer board on the right. The 3 in. pipe connection with gate valve from the air meter to the carbureter chamber and the flexible tube from the carbureter to the vacuum pump are plainly shown

Two inclined pressure gages of the pitot tube type are used for determining the pressure drop across the orifice. The tubes are provided with a millimeter scale, and in order to be able to obtain readings directly in inch measures, they are set at such an angle that each division of the scale is equal to a vertical rise of the column of 0.01 in. In this way readings can be made to within a limit of accuracy of plus and minus 0.0025 in. At the left of the carbureter chamber there is a vertical water column with a scale divided into fiftieths of an inch, which can be read through a magnifier, provisions being made to avoid errors due to parallax.



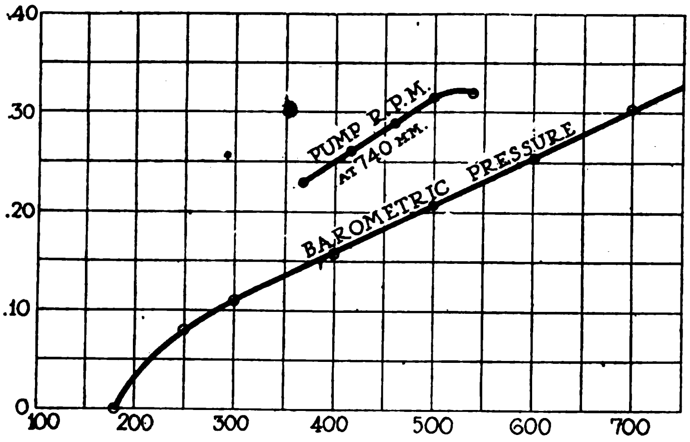
This view shows the fuel tank mounted on a weighing scale with tank pressure gage, vapor trap, stopwatch, electric control and electric buzzer which gives an audible signal when the predetermined weight of fuel has been withdrawn from the tank and the scale beam drops

For controlling the pressure within the carbureter chamber so as to permit of a study of carbureter operation under conditions similar to those encountered at high altitudes, a gate valve is inserted in the air line and connected to the orifice chamber by a piece of 3-in. pipe. The air, after having passed through this gate valve, is drawn through an electric heater consisting of a chamber within which there are frames carrying coils of electric resistance wire. These resistance coils are connected with controlling switches and a rheostat. Some of the resistance coils are connected directly across the 220-volt circuit; two are so arranged that they can have either 110 or 220 volts applied to them, and one of these in addition has a rheostat connected in circuit with it, so that the current flow can be further regulated. By means of the control switches and rheostat the temperature rise of the air can be closely regulated between the limits of 3 deg. and 45 deg. C. above atmospheric temperature, under conditions of maximum air flow. The temperature within the chamber can be read off from a mercurial thermometer mounted just inside the glass door.

Construction of Carbureter Chamber

From the heater the air flows through an approach, shaped like an inverted funnel, into the carbureter chamber, entering the latter through a grid similar to that provided in the approach to the air meter. The purpose of the grid and of the funnel-shaped approach to the carbureter chamber is to prevent the formation of eddy currents, which would be sure to result if the air entered the chamber in a small stream of high velocity.

The carbureter chamber consists of a box made of 2-



Curves showing the operation of the Nash turbine pump used in the carbureter tests

in. boards reinforced along the inside corners by lengths of angle iron. The outside dimensions of the box are 18 x 18 x 30 in. The door comprises a frame of square steel bars, to which is applied a galvanized iron sheathing, the edges of which are turned up at the door opening. The joint between the galvanized iron and steel bars is sealed by means of solder and an airtight joint between the door and the door frame is effected by the use of a rectangular gum rubber gasket. The glass door fitted is of ¾-in. plate glass and is held in place over the opening and against the gasket by a pair of steel bars.

Centrally in the top wall of the chamber there is a circular flange to which any carbureter to be tested can be secured by means of an adapter. To one side of the door opening there is a pair of control shafts which carry adjustable levers inside the chamber, from which connections can be made to the throttle lever and any other control devices with which the carbureter under test may be provided. The hub of the flange on the top of the carbureter chamber extends through the wall of the chamber and on the outside carries a large circular flange. In order to permit of studying the character of the mixture produced by the carbureter, the outlet is made in the form of a glass tube which is held in glands secured by 4 studs. Passing the mixture as it leaves the carbureter through a glass tube enables observation to be made of the quality of the mixture as regards fineness of division of the fuel, of any irregularities in the fuel discharge, of any swirling effect in the mixture stream and of any unequal division of the fuel in the stream or on the walls. The use of a glass tube and outlet pipe also serves as a check on the action of the float mechanism of the carbureter.

Pulsator

Considerable interest attaches to the device employed for creating a pulsating suction in the air passages, referred to as a pulsator, which is located directly above the carbureter, as this is probably the first time that such a device has been used in carbureter tests. This pulsator comprises a cast body with a rectangular passage for the fuel mixture. A butterfly throttle valve is located in this passage. Two opposite walls at the rectangular passage consist of plates of spring bronze, which are normally flat. These spring bronze plates are located directly over the throttle valve and permit of varying the effective area of the passage at the valve.

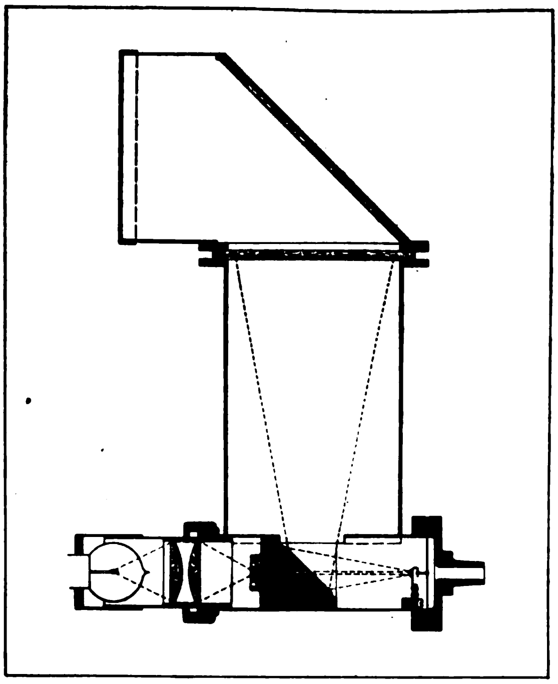
Pulsation of the suction is produced by rotating the valve by means of a 1/6-hp. electric motor which is mounted on top of the carbureter chamber and drives the throttle valve by belt. Stepped pulleys permit of varying the speed of the pulsator valve, and further speed control may be effected by means of resistances in the motor field circuit. In this way the rate of pulsation can be varied between the limits of 600 and 4000 per minute, which corresponds to a range of engine speed of 300 to 2100 r.p.m. for 4-cylinder engines and 400 to 2800 r.p.m. for engines in which one carbureter supplies three cylinders. A tachometer serves to indicate the speed of the pulsator valve. This is of the type designed to be fitted to the camshaft of an engine, and its indications are always equal to twice the number of revolutions per minute at which it is driven. As the throttle valve produces two pulsations per revolution, the tachometer indicates directly the pulsations per minute.

Optical Indicator

The amplitude of the pulsations can be varied by means of screws pressing against the spring bronze plates and forcing them more or less toward the throttle sweep. In this way it is possible to closely reproduce the pulsating suction characteristics of any engine in which explosions follow one another at equal intervals. Indications of the magnitude of pressure fluctuation are given by a simple form of optical indicator provided with a graduated screen. A line of light appears on this screen, the ends of which represent the pressure limits.

For creating the suction on the carbureter, use is made of a Nash vacuum pump which connects to the pulsator by means of a flexible metallic tube and which discharges outside the laboratory. Adjacent to the pulsator outlet, a throttling opening and trap is inserted in the line. This serves to prevent any effect upon the carbureter action of possible resonance in the flexible tube due to the pulsator action, and also to dispose of any liquid in the mixture above the pulsator, especially at low air velocities, which is passed from here directly to the pump intake (through a ⅜-in. inclined pipe).

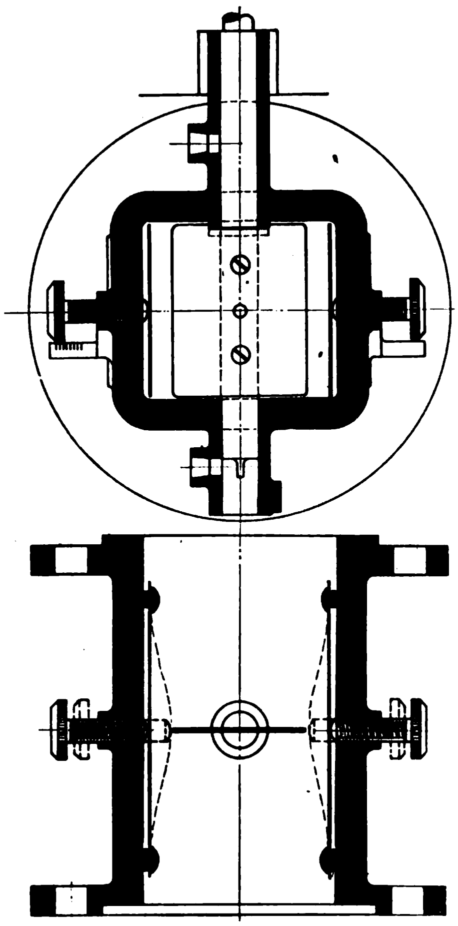
The fuel delivered by the carbureter is measured by weighing. From a 30-gal. tank on a platform scale it is



In the carbureter tests a pulsating suction corresponding to the strokes of a running engine is created by means of a vacuum pump. The magnitude of these pressure fluctuations is noted on the screen of the optical indicator shown above. A beam of light is reflected from a mirror, at the lower right of the device, connected to a diaphragm

forced under pressure to the carbureter float chamber, a gage on the tank indicating the pressure on the fuel (which is usually maintained at 2 lb. per sq. in. by means of a regulating valve in the pressure line). The pressure here referred to is the difference in pressure on the fuel in the tank and that in the carbureter chamber. Beyond the pressure regulating valve there is a vapor trap in the line, mounted on top of the tank, and thence the fuel passes through a copper tube to a valve and fitting in the top wall of the carbureter chamber, from which a length of airplane fuel hose connects to the carbureter.

The beam of the fuel-weighing scale is provided with a mercury contact device by means of which an electric circuit is completed which controls the stopping and starting of a stopwatch, and also the electric circuit of an annunciator, so that an audible signal is given to the operator when the run begins and ends. As the stopwatch is started and stopped automatically, the human equation is entirely eliminated in the determination of the fuel delivery. This method has the further advantages that it relieves the operator of the necessity of minding the fuel scales, leaving him free to devote all his attention to the other indicating devices and to the control of the carbureter.



Construction of rectangular pulsator and butterfly valve and plates for varying effective area of the passage

Twelve pressure gages are made use of in connection with this test installation. These extend into the carbureter chamber, the connections being made at the door, where union fittings are soldered into the galvanized iron sheathing, the connections being made by copper tube outside the chamber and by rubber hose inside. The scales of the water columns are so arranged that they can be adjusted vertically as a unit, in accordance with the level in the header from which the columns draw their water. This permits of resetting the scales during the run to allow for the displacement of the zero as water is transferred from the header to the columns. However, the tank is of such size that even if three of the columns should be in use simultaneously and should be entirely full of water, the error due to the change in the zero position would be less than 1 per cent. In addition to the six columns referred to and the main barometer for indicating the chamber pressures, there are mounted on the board a pair of mercury U tubes and a supplementary U-tube barometer. By means of T fittings and tubing within the chamber the various columns can be interconnected in different combinations.

The air pump is driven by a 25-hp. shunt motor which is provided with controlling resistances for the field circuit. When the pump is in operation the rate of air flow through the carbureter depends upon the position of the carbureter throttle, the position of the throttling valve adjacent to the air heater and the position of the gate valve on the pump intake. The gate valve determines the depression in the carbureter outlet, and hence the rate of air flow through the carbureter, while the throttling valve adjacent to the air heater exerts an influence upon the pressure, and consequently upon the density of the air in the carbureter chamber, and in this way has an effect upon the rate of air flow through the carbureter.

The chief object of the carbureter test plant is to determine quickly the ratio of air to fuel passed under any given conditions. First of all the outfit must be adjusted to pass the required quantity of air under conditions of predetermined atmospheric and carbureter outlet pressures. The first step when such a test is to be made is to select the proper air meter orifice and put it in position. This selection is facilitated by the use of graphs which have been prepared for each of the orifices regularly used, showing the amount of air in pounds passed per second as a function of the pressure difference. Next, the pump intake by-pass and the throttling valve are adjusted to give the required indication of the pressure gage, showing the orifice pressure at the predetermined pressure in the carbureter chamber. With a given setting of the throttling valve, subsequent adjustment of either the orifice pressure or the carbureter chamber pressure will automatically entail readjustment of the other. Then the carbureter throttle is adjusted to give the carbureter outlet pressure corresponding to the predetermined chamber pressure and drop in the carbureter.

The rate of air flow through the carbureter and conditions of inlet and outlet pressure being now fixed, the weights on the fuel scale are adjusted so the beam is about to drop. As a result of withdrawal of fuel from the tank by the carbureter, the beam soon drops and starts the stopwatch. Then a weight is removed from the scale corresponding to the amount of fuel it is desired to pass through during the test, and when this has been withdrawn from the tank the scale again drops, closing the electric contact and stopping the stopwatch. While the run is on, the operator observes and records the indications of the thermometric apparatus, the pressure gages, tachometer, pulsation indicator, etc. At the end of the run he has the amount of the air and fuel delivered and the time occupied in passing these quantities of air and fuel. This completes the run.

So far most of the development work that has been carried out in this carbureter test plant has been with large size aircraft engines which had been tested previously, so that the rates of air and fuel flow were rather closely known in advance. However, the plant has been designed to permit of a wide range of adjustment, a fact which will render it all the more useful now that lines of automotive work other than aircraft development will regain their pre-war importance.

THE Derbyshire (England) oil boring operations are said to have met with encouraging success recently. At Hardstoft much water has been met with, which has delayed progress, but several gushes of gas have been encountered which are associated with the presence of oil. At Brimington, following repeated gushes of gas, the first traces of oil have been encountered. It is of the rough character known as "farmers' oil," but gives off an odor of paraffin. Receptacles for conserving oil, if it is tapped in quantity, are being arranged on the spot.

New Golden, Belknap & Swartz Truck and Tractor Engine

Will Enter Production in March with L-Head, 3¾ by 5-In. Powerplant, Adapted to Low-Grade Fuel — Built for Truck and Tractor Service

THE Golden, Belknap & Swartz Co., Detroit, will be in production toward the end of this month on a new truck and tractor engine. This is a 3¾ in. by 5 in., four-cylinder model, known as the AA, designed to handle low-grade fuel and is a new product in every respect, arranged to have the most advanced practice in detail design.

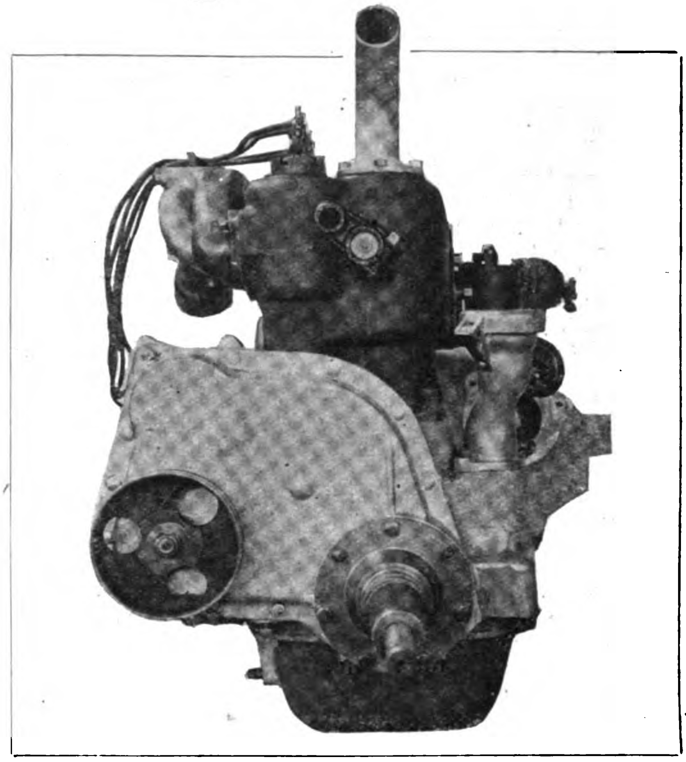
The engine is laid out generally to accommodate itself to the demands of truck and tractor manufacturers and to fit the requirements of their particular chassis. The carbureter, for example, can be mounted on the left or right side of the engine. Thermo-syphon or pump water circulation can be used and battery or magneto ignition is suitable, driving facilities being arranged to take care of either.

If the engine is used in tractor service, an oil cooler can be fitted, and if it is desired to mount a governor, there is a vertical shaft with a slotted end to take the governor drive and a flange face upon which to mount it. The engine is a fixed-head type with removable water header. Both halves of the crankcase are aluminum and the cylinders are cast in a block of gray iron.

The pistons are the three-ring type, with oil relief holes drilled circumferentially below the lower ring to prevent oil pumping into the cylinders.

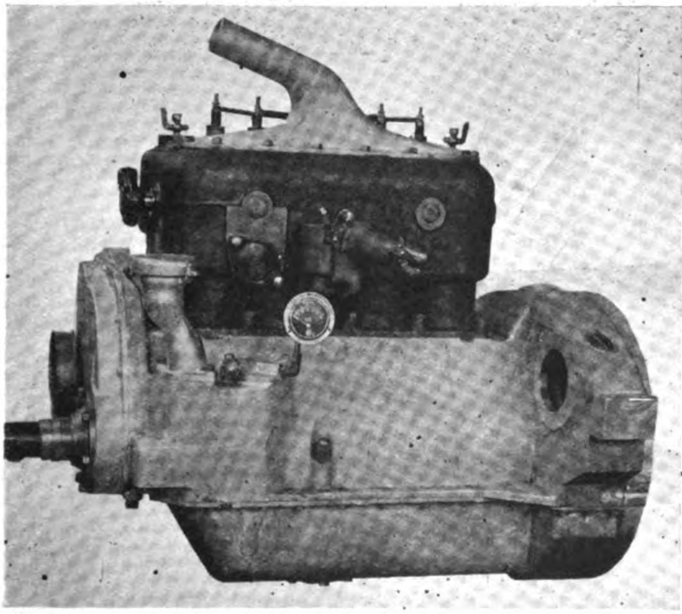
There are also two grooves at the bottom of the piston skirt which act as oil retainers. The piston pin is anchored in the boss and the weight of the piston complete with the wrist pin and rings is 3 lb. 1 oz. The length of the piston is 3¾ in. The wrist pin bearing is 1½ in. in width and 1 in. in diameter.

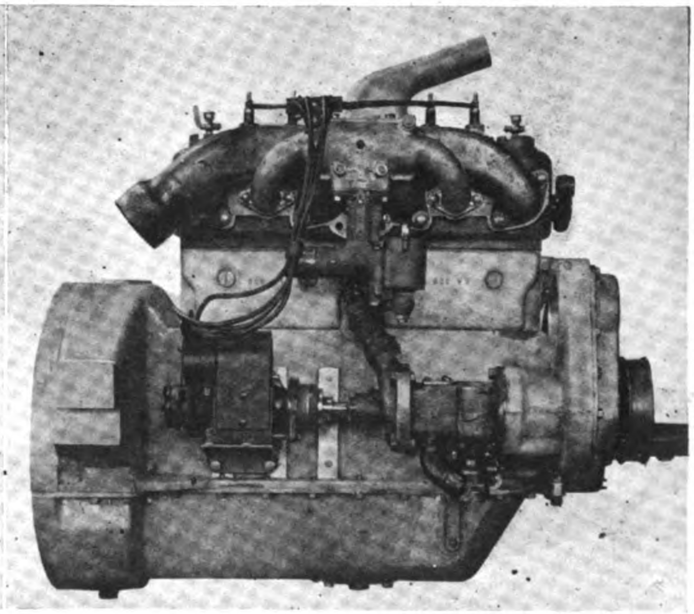
The connecting-rods are 10¼ in. in length, center to center.



Front end of new Golden, Belknap & Swartz 3¾ by 5 in. truck and tractor engine

They are machined quite closely for light weight. The weight of the connecting-rods is 2 lb. 4 oz. They are provided with lower bearings, 2 3/16 in. in width and 1⅞ in. in diameter. The crankshaft is 2¼ in. in diameter and is carried on three main bearings, the front being 3 in. in length, the center 2⅛ in., and the rear 3 in. Both the main bearings and the connecting-rod bearings are bronze-back, babbitt lined.





Left side of Golden, Belknap & Swartz engine, showing carbureter mounted on left side and detachable flange cover for thermo-syphon cooling; and right side, with carbureter mounted for hot spot manifold and magneto

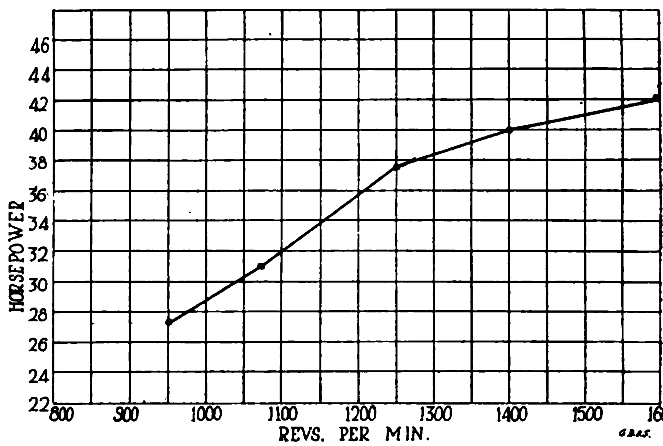
The three bearings for the camshaft are die-cast babbitt. The main and connecting-rod bearings have the new Muzzy Lyon babbitt adjustment in place of shims. This is a solid piece of babbitt metal of the thickness of the ordinary group of shims, but has the advantage that it can be inserted beyond the inside of the bearing and then burnished out to form a part of the true bearing surface, eliminating the ordinary outlet for the oil which exists in the shimmed bearing.

The babbitt is undercut at the center of the length of the bearing, so as to line up with the oil groove in the bearing, permitting the oil to have free flow at the bearing surface. When necessary to adjust the bearings, the babbitt can be filed down to any amount, thus permitting of very accurate settings on the bearings.

The main bearings are supported in the crankcase, the center bearing being very heavily ribbed to give the desired rigidity and continuity of alignment. Each of the main bearing caps is held in place by four alloy steel stub bolts with castellated nuts, cotter-pinned into position. The timing gears are helically cut and are steel against semi-steel. The camshaft is on the right side of the engine and is an integral forging with large bearings.

The valves are driven through mushroom tappets, the tappet guides being locked by spiders bolted to the crankcase. Adjustment is made by means of a stud screwed into the end of the tappet and locked by a locknut. The valves have a port diameter of 1 11/16 in., and have a lift of 23/64 in. The valve passages are clear and of ample size, as will be noted from the illustration showing the cylinder block with the valve ports exposed.

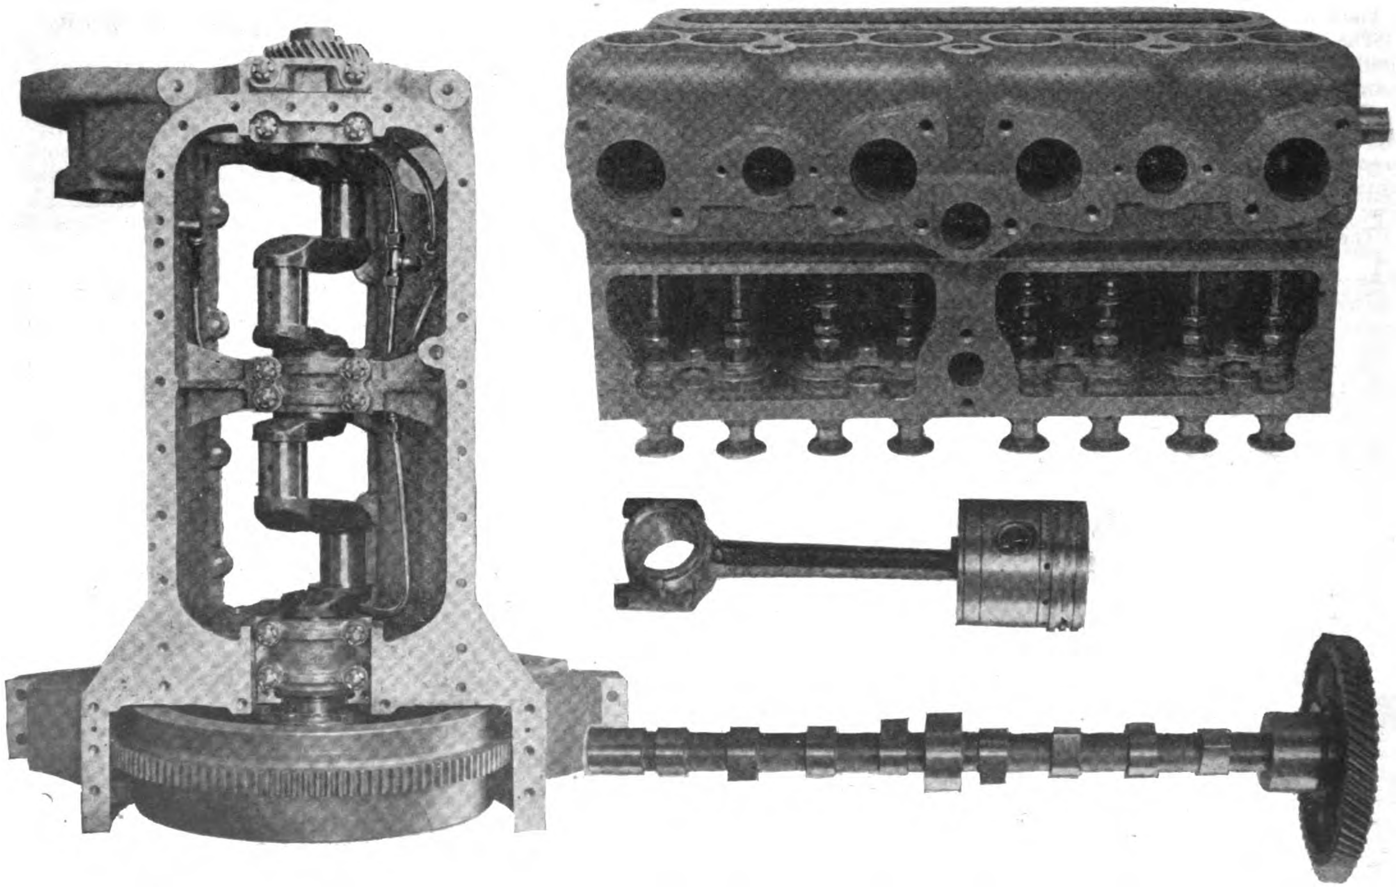
The course of the intake gases depends upon the side of the engine upon which the carbureter is mounted. When the mounting is as shown in the illustration herewith, the hot spot type of manifold is used with the intake partially integral with the exhaust, securing the desired preheating effect. The hot spot construction is used even if the carbureter is mounted on the opposite side, as the store is so arranged that the intake gases are drawn from the store between the cylinder blocks.



Horsepower curve of new Golden, Belknap & Swartz 3¾ by 5 in. truck and tractor engine

Lubrication is by full pressure system, with no splash. The oil pump is driven off the water pump shaft and is a gear type. It is mounted on the exterior and can thus be readily removed for inspection. Pressure can be regulated to suit requirements. There is provision for mounting a pressure gage on the dash, this gage being shown closely connected to the engine in the left-side view. The oil relief or pressure regulation is external, being readily made with a screwdriver and wrench. This adjustment is located on the outside of the engine at the point at which the oil filler neck leaves the crankcase.

Under ordinary conditions the oil is fed under a pressure of 15 lb. per sq. in. The oil leads are self-contained, taking the oil from the pump direct to each of the three main bearings, and another lead for pressure passes through the pressure gage. The crankshaft is drilled through the cheeks to



Cylinder block of Golden, Belknap & Swartz truck and tractor engine and piston and connecting rod and camshaft assemblies

the crank pin, which is also drilled to feed the oil to the lower connecting-rod bearing. As the oil is fed under pressure and since it is supplied in superfluous quantities, there is a marked spray off the lower ends of the connecting-rods which lubricates the internal walls of the cylinder.

In ordinary practice, the engine will be cooled by pump circulation. The water pump and the magneto are driven off the same shaft when magneto ignition is used, and this same longitudinal shaft also provides a drive for the oil pump, as well as for the governor when fitted. A study of the water outlet header will show that this is suitable for either pump or thermo-syphon circulation. Should the thermo-syphon cooling be used, the cap flange on the left side of the engine is removed and the water connection made here instead of at the pump.

No accessories are furnished with the engine. The mounting is designed for three-point suspension, and the overall dimensions are 34 1/16 in. in length, 31 in. in height and 23⅛ in. in width. The engine is produced with a No. 3 S. A. E. bell housing as standard, the starting motor mounting being in this bell housing. There is a generator mounting on the rear of the timing gear housing on the right side of the engine, if the magneto is used, or the generator may be mounted on the shelf in which the magneto is shown in the accompanying illustration. These various locations for mounting different accessories or auxiliary units give the engine a very elastic make-up.

The general power characteristics of the engine as shown from tests on the fan dynamometer give 42 hp. at 1600 r.p.m., with the maximum torque at 800 r.p.m. The governed speed is 1400 r.p.m. The weight of the engine without ignition system or carbureter is 410 lb.

British Papers on Motorcycle Design

ABOUT a year ago there was considerable discussion in the British press in regard to the need of some method of ventilating and discussing the difficulties with which designers of motorcycles were faced. The matter was immediately considered by the Council of the Institution of Automobile Engineers, and after a conference with technical representatives, of some of the motorcycle manufacturing firms, the Institution undertook to arrange meetings to deal specially with points in connection with motorcycle design, provided that sufficient support was forthcoming from those interested in that branch of the industry. A large number of motorcycle engineers have since joined the Institution, we are informed.

Two meetings were arranged in Birmingham, to form part of the regular Institution session, and the papers for these meetings deal specifically with points connected with the design of motorcycles. The first paper, which was read at the Birmingham Chamber of Commerce on February 20, by D. S. Heather, was entitled "A Survey of Current Motorcycle Design."

Mr. Heather wrote as a rider, rather than as a designer of motorcycles, and this was perhaps rather fortunate, for it is believed that it is just this point of view that the motorcycle manufacturers often lack. The criticism made by Mr. Heather was not entirely uninformed, however, as he has been connected with the motor car side of the industry for some time.

The second paper on the subject will be read on March 20, at the same place, by Eric Caudwell, and is announced to be composed chiefly of constructive criticism.

New Organization of the United States Air Service

WASHINGTON, March 17—Maj.-Gen. Chas. P. Menoher, Director of Air Service, has announced a new organization as follows:

Executive Staff

Executive Officer, Col. Milton F. Davis, A.S., A.
First Assistant Executive, Col. William E. Gillmore, A.S., A.
Second Assistant Executive, Maj. Horace M. Hickam, A.S., A.
Third Assistant Executive, Brig. Gen. William Mitchell, U. S. A.
Fourth Assistant Executive, Lt. Col. William F. Pearson, A.S., A.

Technical Advisory Staff

Supply

Chief, Air Service Property, Lt. Col. Augustine W. Robins, A.S., A.
Chief, Air Service Procurement, Col. Chalmers G. Hall, A.S., A.
Chief, Air Service Materials Inspection, Lt. Col. George W. Mixter, A.S., A.P.
Chief, Air Service Finance, Lt. Col. Alex. C. Downey, A.S., A.P.
Chief, Air Service Aeronautical Engineering, Col. Thurman H. Bane, A.S., A.

Training and Operations

Chief, Air Service Training (Detail to be announced later).
Chief, Air Service Operations, Lt. Col. Lewis H. Brereton, A.S., A.
Chief, Air Service Gunnery, Lt. Col. Harold E. Hartney, A.S., A.
Chief, Air Service Communications, Col. Clarence C. Culver, A.S., A.
Chief Air Service Balloons and Airships, Col. Charles DeF. Chandler, A.S., A.

Administrative Staff

Chief, Air Service Personnel, Lt. Col. Rush B. Lincoln, A.S., A.
Chief, Air Service Inspector, Lt. Col. Frank M. Andrews, A.S., A.
Chief Surgeon, Air Service, Col. Albert E. Truby, M.C.

The following named officers have been designated as an Advisory Board, Air Service:

Col. Walter G. Kilner, M.A., A.S.A.,
Col. Arthur L. Fuller, A.S.A.,
Col. Henry C. Pratt, A.S.A.,
Lt. Col. George B. Hunter, A.S.A.,
Lt. Col. Henry W. Harms, J.M.A., A.S.A.,
Maj. Charles R. Cameron, A.S.A., Secretary.

and the following named detailed for duty in the Office of the Director of Air Service, as indicated:

Assistant to Executive Officer, Lt. Col. Oscar Westover, A.S., A.P.

Assistant to Second Assistant Executive, Maj. John B. Reynolds, A.S.A.

Assistant to Third Assistant Executive, Col. Thomas DeWitt Milling, M.A., A.S.A.

Assistant to Fourth Assistant Executive, Maj. Walter H. Frank, J.M.A., A.S.A.

Assistant to Fourth Assistant Executive, Maj. Raycroft Walsh, J.M.A., A.S.A.

Assistant to Chief, Air Service Materials Inspection, Lt. Col. John D. Reardan, A.S., A.P.

Assistant to Chief, Air Service Finance, Lt. Col. Jacob E. Fickel, J.M.A., A.S.A.

Assistant to Chief, Air Service Finance, Lt. Col. William C. McChord, J.M.A., A.S.A.

Assistant to Chief, Air Service Aeronautical Engineering, Lt. Col. Byron Q. Jones, M.A., A.S.A.

Assistant to Chief, Air Service Training, Lt. Col. Herbert A. Dargue, M.A., A.S.A.

Assistant to Chief, Air Service Personnel, Lt. Col. Hollis C. Clark, A.S., A.P.

Legal Advisor to Director of Air Service, Maj. J. Gowan Roper, J.A.

The following chart explains the various functions of the Executive Staff:

Director of Air Service

Advisory Board ... { Executive Officer, Col. M. F. Davis } Foreign Representation (to be announced later)

Col. W. G. Kilner.
Col. A. L. Fuller.
Col. H. C. Pratt.
Lt. Col. G. B. Hunter.
Lt. Col. H. W. Harms.
Maj. C. R. Cameron.

EXECUTIVE STAFF

1st Asst. Executive,
Col. W. E. Gillmore.
Technical Advisory Staff, supply:
Chief, A. S. Property, Lt. Col. A. W. Robins.
Chief, A. S. Procurement, Col. C. G. Hall.
Chief, A. S. Materials Inspection, Lt. Col. A. C. Downey.
Chief, A. S. Aero. Engineers, Col. T. H. Bane.

2nd Asst. Executive,
Maj. H. M. Hickam.
Information,
Statistics,
Publicity.

3rd Asst. Executive,
Brig. Gen. William Mitchell.
Tech. Advisory Staff,
Training and Operations,
Chief, A. S. Training (to be announced later).
Chief, A. S. Operations, Lt. Col. L. H. Brereton.
Chief, A. S. Gunnery, Lt. Col. H. E. Hartney.
Chief, A. S. Communications, Col. C. C. Culver.
Chief, A. S. Balloons and Airships, Col. C. DeF. Chandler.

4th Asst. Executive,
Lt. Col. W. F. Pearson.
Administrative Staff:
Chief, A. S. Personnel, Col. R. B. Lincoln.
Chief, A. S. Inspector, Lt. Col. F. M. Andrews.
Chief Surgeon, A. S., Col. A. E. Truby, M.C.
Routine Executive. A. S. Functions.

Walker Automatic Gear Tooth Rounding Machine

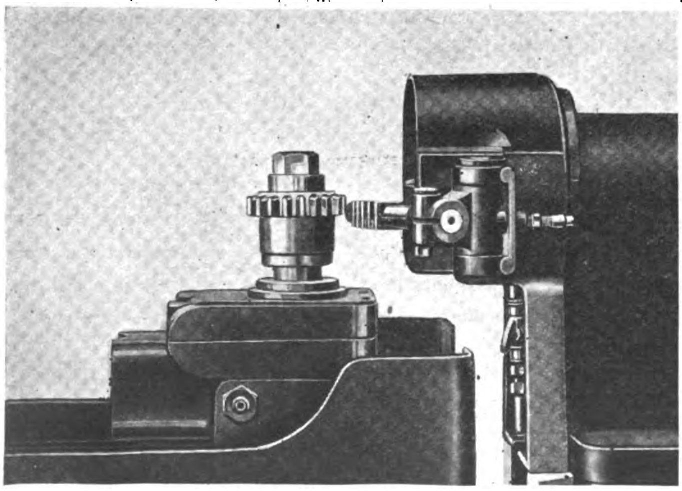
Can Be Set to Round Meshing Edges, or to Remove Burrs Left by Cutters or Hobs

ROUNDING the edges of teeth of sliding meshing gears, such as are used in gearsets, presents a peculiar problem in machining which necessitates the use of a special machine. The newest of these has been brought out by the Charles H. Walker Machinery Co., Detroit. This machine can be used either for rounding the meshing gear edges or it can be so set up as to efficiently remove the burrs left by the cutter or hob on spur gears, straight and spiral bevel gears, helical gears and worm wheels.

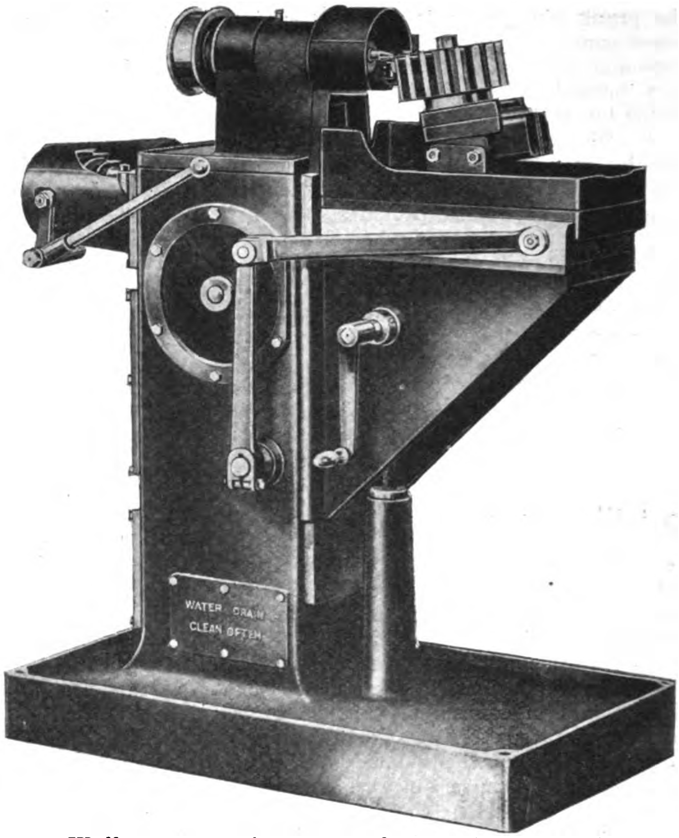
The machine has capacity for any gear up to 30 in. diameter by 12 in. face and of any standard or special pitch from 20 to 2½ pitch and of any number of teeth. When used for rounding purposes the machine will round the entire end of the tooth for 180 deg. at any desired radius. In rounding the tooth the cutter takes off the surplus metal at the root of the tooth, thus freeing the gear of burrs and eliminating the filing work sometimes necessary.

The gear is held rigidly during the cutting operation. The cutter starts at one side of the tooth and works around it, finishing on the other side. Owing to the fact that the gear is held rigidly during the cutting operation, there is no backlash and the cutter cuts both sides of the tooth equally. There is a quick return movement to bring the cutter back to its starting position rapidly. While the cutter is going back to starting position the table is moved out and in, bringing the next tooth to be rounded in mesh with the indexing rack, thus automatically indexing and centering the tooth in correct relation to the cutter.

The indexing rack is cut with teeth of the same pitch as the gear to be rounded. It meshes a trifle below the top of the gear so as not to interfere with the cutter, and due to its solid mesh the indexing rack holds the tooth being cut rigidly throughout the cutting operation. The indexing method is simple, getting away from change gears, ratchets and other devices.



Indexing mechanism, showing how indexing rack meshes with gear below its top surface



Walker automatic gear-tooth rounding machine

Owing to the automatic operation of the machine, one operator can handle a number, depending on the class of work. Ordinarily, an operator can handle three to four machines on a production basis. The cutter spindle is driven by an independent shaft and is mounted in a double eccentric, allowing the spindle to be offset to accommodate gears up to 2½ pitch.

The driving mechanism is enclosed and includes a three-step cone pulley. There is a clutch shift lever to stop and start. The machine camshaft is driven from the powershaft by a worm drive, and the camshaft is lubricated by a belt carrying an oiler spring which picks up oil out of the reservoir in the sump below the camshaft in the main body of the machine. This oiler spring lubricates both the cams and cam rollers, worm and worm wheel. The drive from the camshaft controls the operation of the table and also the oscillation of the cutter.

For the motion of the table the cam operates through lever arms which are shown in the exterior view of the machine, and for the oscillation of the cutter the motion is imparted by a rack which is operated from the cam. The pinion operated by the rack is solid on the same shaft as the gear wheel, which meshes with the spindle sleeve. The upward motion of the rack revolves the pinion half way around, causing the entire spindle head to operate. The cam is so shaped that a quick-return movement is given to bring the cutter back to its original position.

The machine is fully equipped with the customary adjustments. The elevating screw gives 12 in. vertical adjustment to the knee. The arbor support will hold the gears in any desired position, there being an adjustable work head which can be tilted forward 20 deg., allowing the tooth to be rounded without reducing its face, the angle of course being set to conform with the pressure angle of the teeth.

The work head is fastened to T slots in the table and there is a removable table splash pan. The cutting compound is carried in the base of the machine and is pumped by a plunger pump, operated by an eccentric off the powershaft. The cutting compound is carried to the work and guided by means of a removable cutter splash guard to the table splash

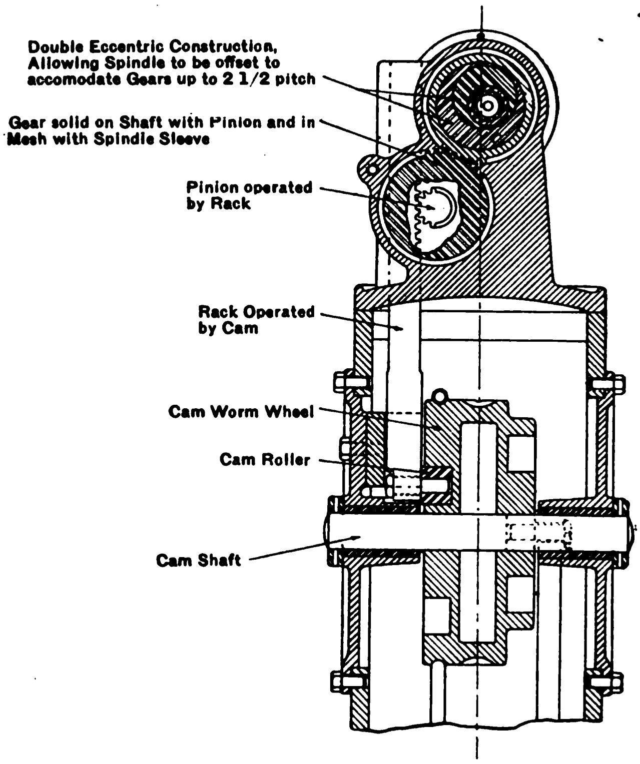
Diagram of indexing mechanism, showing cutter and starting position



Method of driving cutter by means of rack and pinion

pan, draining back to the base without piping at any position of the knee or table, owing to the enclosed knee construction.

The cutters are made with the same angle as the pressure angle of the tooth. The point of the cutter is cut off as much as possible, so that the cutter just fits in the tooth space. Therefore, the larger the pitch the larger and stubbier the cutter. The end of the cutter acts as an end mill and removes the surplus metal at the root of the tooth.

The present machine is based on the machine designed in 1912 by Fred Heal of the Detroit Standard Gear Co., Detroit. All of the patent rights on this type of machine have been assigned to the Charles H. Walker Machinery Co.

Norwegian Grinding Wheels

A NORWEGIAN company in Arendal is supplying grinding wheels produced in electric furnaces. Their "Sika" wheels, suitable for castings and coarse work, are made of fused carbide o fsilicon (SiC.), which produces gray-green crystals of great hardness, generally known as "carborundum." Their "Durabit" wheels (suitable for grinding hard steel) are made of aluminum oxide (Al_2O_3), known as artificial corundum, obtained by fusing bauxite into red-brown crystals.

The crystals are ground to powder and sorted mechanically, ranging from No. 10, which is the coarsest, to No. 250, which is the finest polishing "flour." To produce grinding wheels, the powders are generally mixed with some binding medium as clay having a melting point of 2200 to 2500 deg. F. The discs are first formed in hydraulic presses, then exposed to the above temperature in an electric furnace, where the clay fuses and the whole becomes a hard, homogeneous mass. The hardness is proportionate to the quantity of clay used.

Shellac or water glass is also used as binding materials, in which case the temperature varies from 350 to 550 deg. F.

All wheels are provided with lead bosses and turned in the lathe after completion so as to be accurately centered. The elastic shellac wheels are turned with diamond tools, the others by rotating conical steel cutters.—*Teknisk Ukeblad.*

On Proportioning Engine Bearings*

An Analysis of the Crank-Bearing Loads in a Four-Cylinder, Three-Bearing Truck Engine Under Different Conditions of Operation

By Otto M. Burkhardt

Longer Center Bearings

In this article, Mr. Burkhardt, who is mathematical research engineer for the Pierce-Arrow Motor Car Co., shows that in a 3-bearing 4-cylinder engine, as commonly used on motor trucks, the load on the center bearing is very much greater than most designers realize, to judge by the dimensions they give to this bearing.

All the factors on which the load depends, viz., explosion and compression pressures, inertia forces of engine reciprocating parts and centrifugal forces on rotating parts, are taken into consideration, and the loads are determined for both low speed-full load and high speed-no load operating conditions.

Mr. Burkhardt finds that the center bearing should be considerably longer even than the rear end bearing, which, in addition to its other loads, has to carry the weight of the flywheel.

THERE exists considerable uncertainty among designers regarding the proper proportions for crankshaft bearings. The writer therefore has worked out a method for determining these proportions, based on the principle that the necessary dimensions are a function of the load the bearing has to carry. A separate analysis is required for each type of engine, and in this paper we will confine ourselves to the most popular of all types, the four-cylinder four-stroke engine. The analysis will be further limited by assuming the engine to be intended for motor truck work.

First of all, it is necessary to ascertain the bearing loads pertaining to the four limiting conditions of operation:

1—Engine running light at low speed.
2—Engine running at low speed under full power.
3—Engine running light at maximum speed (1000 r.p.m.).
4—Engine running at maximum speed under full power.

Case I.

In Case I, the loads acting on the crankshaft will necessarily be very small—in fact, negligible. We may, therefore, dismiss this case as of no consequence.

Case II.

In this case, on account of the low speed we may neglect the centrifugal and inertia forces. There are then left for consideration the pressures due to the gaseous mixture (expansion and compression strokes).

The mean pressure during the expansion stroke we will denote by P and the mean pressure during the compression stroke by p. The average pressure on any one crank pin during four consecutive strokes, *i. e.*, expansion, exhaust, suction and compression, is then

$$p' = \frac{P + O + O + p}{4} = \frac{P + p}{4}$$

From the diagram, Fig. 5, which is laid out for a particular engine to be specified further on, we obtain

$P = 2380$ lb. and $p = 272.5$ lb.

Hence for this specific case we obtain an average crank pin pressure of

$$p' = \frac{2380 + 272.5}{4} = 663 \text{ lb.}$$

The crank pin load is divided between the main bearings in definite proportions. Referring to Fig. 1, we note that these partial loads on main bearing I may be expressed as follows:

*From a paper read before the Buffalo Section of the S. A. E.

Load during expansion in cylinder I $= P \times \frac{a}{c}$ lb.
" " exhaust " " I $= O$ lb.
" " suction " " I $= O$ lb.
" " compression " I $= p \times \frac{a}{c}$ lb.
" " expansion " " II $= P \times \frac{c-a}{c}$ lb.
" " exhaust " " II $= O$ lb.
" " suction " " II $= O$ lb.
" " compression " II $= p \times \frac{c-a}{c}$ lb.

From this it follows that the average pressure on main bearing I during one complete cycle is

$$p' = \frac{P\frac{a}{c} + p\frac{a}{c} + P\frac{c-a}{c} + p\frac{c-a}{c}}{4} = \frac{P + p}{4}$$

Exactly the same loads as enumerated above are impressed on main bearing III in consequence of the forces acting in cylinders III and IV. All forces here under consideration act in the same direction. It is, therefore, evident that the average load on the central bearing is equal to the difference between the sum of the average loads on all four crank pins and the loads on the two end bearings. Hence, the average pressure on the central bearing during four strokes is

$$p'' = 4 \times \frac{P + p}{4} - 2 \times \frac{P + p}{4} = \frac{P + p}{2}$$

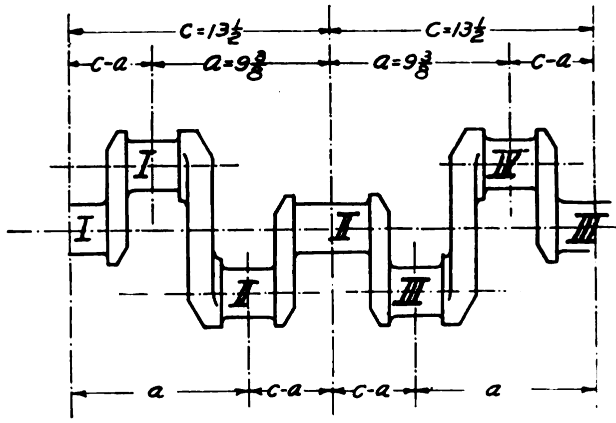

Fig. 1—Layout of crankshaft

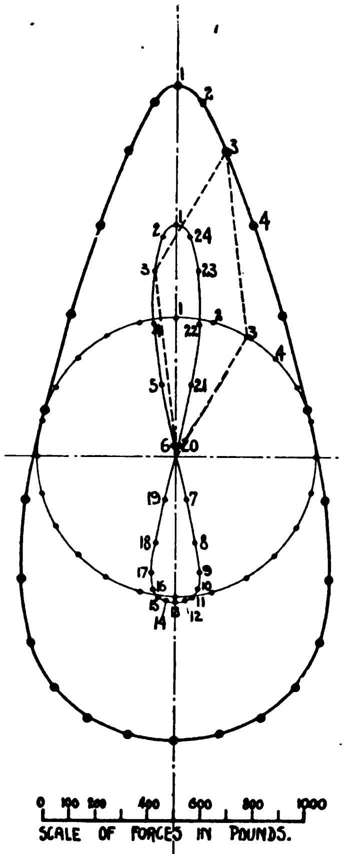

Fig. 2 — Crankpin pressure diagram for light load at high speed

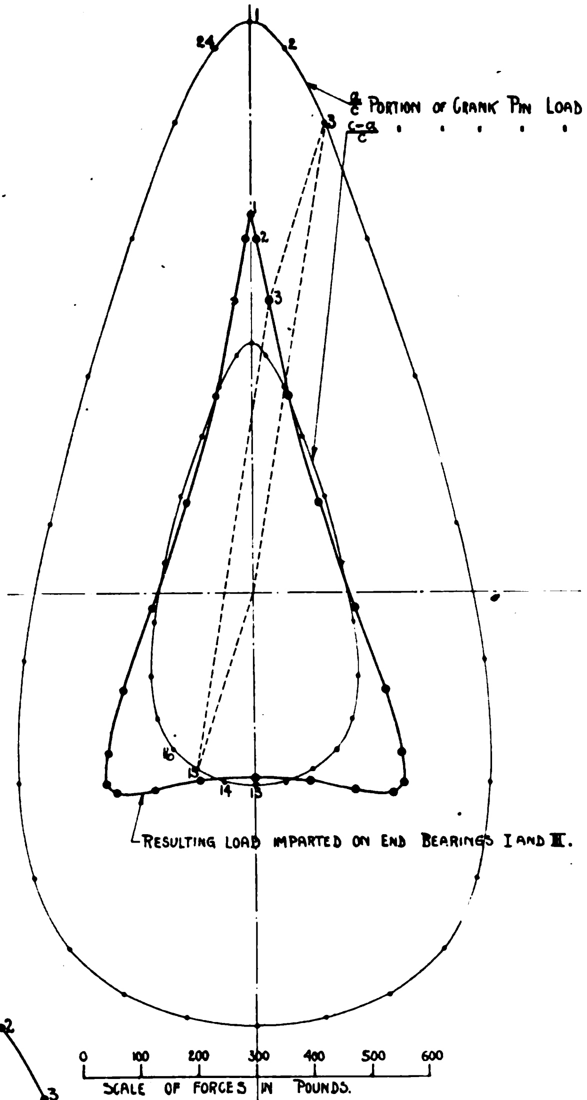

Fig. 3—Diagram showing distribution of crankpin loads between main bearings

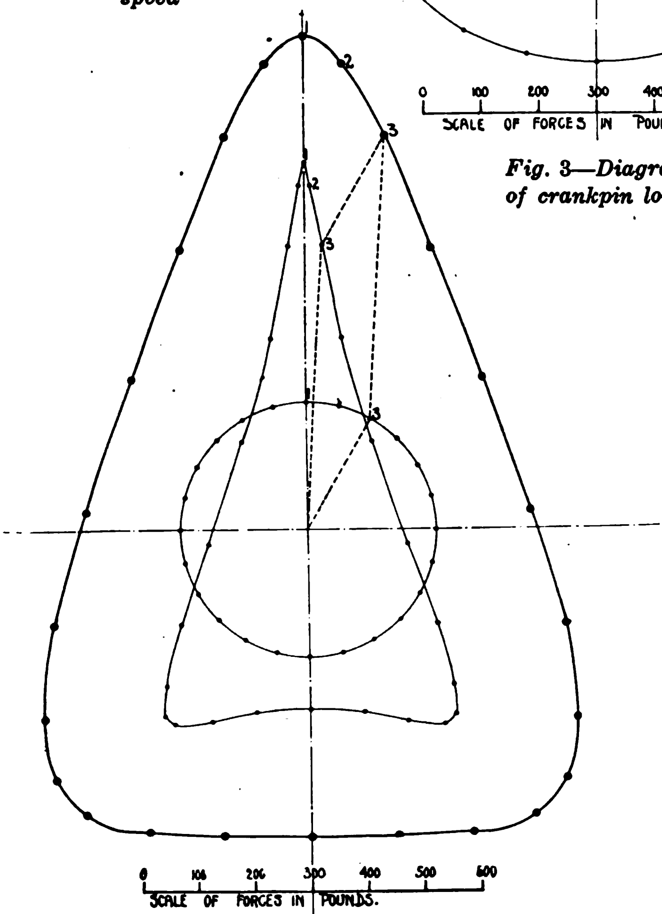

Fig. 4—Resulting loads on end bearings

In our particular example we obtain for the end bearings I and III an average pressure of

$$p' = \frac{280 + 272}{4} = 663 \text{ lb.}$$

and for the central bearing we obtain

$$p'' = \frac{2380 + 272}{2} = 1326 \text{ lb.}$$

Case III.

In this case, we may neglect the pressures due to the gaseous mixture. The only forces to be considered are those due to the inertia of the reciprocating parts and the centrifugal forces. Now, as the inertia forces are affected by the angularity of the connecting rod, and as the centrifugal force is continually changing in direction, no simple universally applicable formula can be evolved for magnitude and direction of the various mean pressures, as in the former case. We shall, therefore, confine ourselves to one particular example, that of a 4-cylinder engine of 4½-in. bore by 6¾-in. stroke. The total reciprocating weight, consisting of the piston with pin, rings, set screw and the small end of the connecting rod, is 7½ lb. The total rotating weight acting on one crankpin is 5½ lb. The inertia and centrifugal forces are all calculated for 1000 r.p.m. of the engine.

The inertia forces acting on the crankpin during one revolution are represented in magnitude and direction by the diagram, Fig. 2, which resembles a lemniscate. This diagram of forces includes certain horizontal component forces which have their origin in the angularity of the connecting rod. The concentric circle shown in the same figure represents the centrifugal forces (530 lb.) acting on the crankpin. If now the inertia forces are combined with the centrifugal forces as indicated by dotted lines for one crank position, we obtain a diagram of elliptical shape which represents magnitude and direction of the resulting loads on the crank pin.

From this latter diagram we find that the maximum load on the crank pin is 1415 lb., the minimum load is 530 lb. and the average load is 940 lb.

These crank pin loads are divided between the main bearings in a definite proportion, as already explained. The partial loads, in the proportions indicated in Fig. 1, are graphically represented in Fig. 3, where they are designated as fractions $\frac{a}{c}$ and $\frac{c-a}{c}$ of the total crank pin load. (Note that a larger scale has been chosen.)

To determine the load on the end bearings, we have to combine components 1, 2, 3 and so on to 24 of the $\frac{a}{c}$ diagram with simultaneously acting component forces of the $\frac{c-a}{c}$ diagram, *i.e.* with 13, 14, 15 and so on to 12. This yields the diagram of resulting forces which is marked "Resulting Loads on End Bearings I and III."

The same principle of combination must be followed in determining the loads on the central bearing. However, since the central bearing is affected by the loads on all of the four crank pins, it is evident that the resulting loads are all twice as large as those acting on the end bearings.

In the present case, we must, further, consider the centrifugal forces due to the crank pins and the adjacent crank cheeks. The crank pin and those portions of the adjacent crank cheeks which are not balanced in their own plane weigh, for the engine under consideration, about 6 lb. The centrifugal force due to this mass is 575 lb. at 1000 r.p.m. If we denote this centrifugal force by C we find by reference to Fig. 1 that each of the two main bearings I and III receives the partial load:

$$L_e = C\frac{a}{c} - C\frac{(c-a)}{c} = C\frac{(2a-c)}{c}$$

Substituting the dimensions given in Fig. 1, we obtain

$$L_e = 575 \times \frac{2 \times 9 - \frac{3}{8} - 13 - \frac{1}{2}}{13 - \frac{1}{2}} = 225 \text{ lb.}$$

Again the load on the central bearing is twice as large as the load on either end bearing, that is, 450 lb. We may now determine the total load on the end bearing which, by virtue of the existing symmetry, at the same time represents one-half of the total load acting on the central bearing.

In Fig. 4 the triangular thin line diagram represents the loads due to connecting rods I and II, III and IV, respectively, on the two end bearings, while the concentric circle represents the centrifugal force of 225 lb. If corresponding forces of these two diagrams are combined, taking account of their phase relation, as indicated by dotted lines, we obtain the resulting forces acting on the end bearings. The resulting diagram (heavy lines) shows a maximum load of 875 lb. and a minimum load of 385 lb., and by summation we obtain the average load of 600 lb. While these loads have been calculated for the two end bearings, we can find from them the loads on the central bearing by simply multiplying them by two. This gives a maximum load of 1750 lb., a minimum load of 730 lb. and an average load of 1200 lb.

Case IV.

In this case we have to deal with the forces due to the gaseous mixture as well as with centrifugal and inertia forces. While the writer does not underestimate the difficulty of determining exactly the forces acting during the expansion and compression strokes, a fair estimate of these forces may be made from the diagram Fig. 5. This diagram has been drawn to conform as nearly as possible to indicator diagrams obtained in practice. It represents a total of 1040 ft. lb. of work, which in the case of a 4-cylinder engine when running at 1000 r.p.m. would mean.

$$\frac{1400 \times 4 \times 500}{33000} = 63 \text{ indicated horsepower.}$$

If we allow about 14 per cent for engine friction, we obtain an effective output of 54 hp. This in turn corresponds to a mean effective pressure of 100 lb. per square inch of piston area. This may be somewhat higher than what is generally obtained with truck and tractor engines; it is, however, less than the rather desirable standard set by aircraft engines which we endeavor to approach.

With this mean effective pressure as a basis, the horsepower output at 1000 r.p.m. can be determined for any similar engine by means of the simple formula:

$$HP = \frac{b^2 s n}{10} \text{ where}$$

b = bore in in.
s = stroke in in.
n = number of cylinders.

The pressure due to the gaseous mixture throughout the stroke, as determined from Fig. 5, together with the inertia forces and certain horizontal components due to the angularity of the connecting rod, are graphically represented by the irregular thin line diagram of Fig. 6. Of course, during the expansion stroke there are gaseous forces of considerable magnitude, while during the next three strokes the inertia forces predominate. This accounts for the reappearance of the same force diagram which was shown in Fig. 2. The circle shown in Fig. 6 represents the centrifugal force acting on the crankpin. If now we combine corresponding forces as before, we obtain the total load on the crankpin as represented by the heavy line diagram.

From the latter we obtain the following characteristic loads:

Maximum = 4075 lb. Minimum = 530 lb. Average = 1230 lb.

These loads are divided between the main bearings in the proportion of $\frac{a}{c}$ to $\frac{c-a}{c}$ These partial loads are represented in Fig. 7. Now, to obtain from these the load on the end bearings we have to combine forces 1, 2, 3 and so on to 24 of the $\frac{a}{c}$ graph with forces 13, 14, 15 and so on to 1 of the $\frac{c-a}{c}$ graph. This yields the irregular thin line diagram shown in Fig. 8. If the resultant forces so obtained are now combined with the centrifugal forces shown in the same figures, we obtain the heavy line diagram which represents the resulting forces acting on the end bearings.

The characteristic loads obtained from this diagram are:

Maximum = 2945 lb. Minimum = 380 lb. Average = 1000 lb.

To obtain the loads on the central bearing due to crankpins 1 and 2, we have first to combine forces 1, 2, 3 and so on to 48 of the $\frac{c-a}{c}$ diagram with 13, 14, 15 and so on to 1 of the $\frac{a}{c}$ diagram. This yields the diagram shown in Fig. 9. This diagram also represents the forces on the central bearing due to crankpins 3 and 4. We must, however, bear in mind that the latter are in phase 360 degrees behind the former. If we, therefore, combine forces 1 to 24 of the diagram in

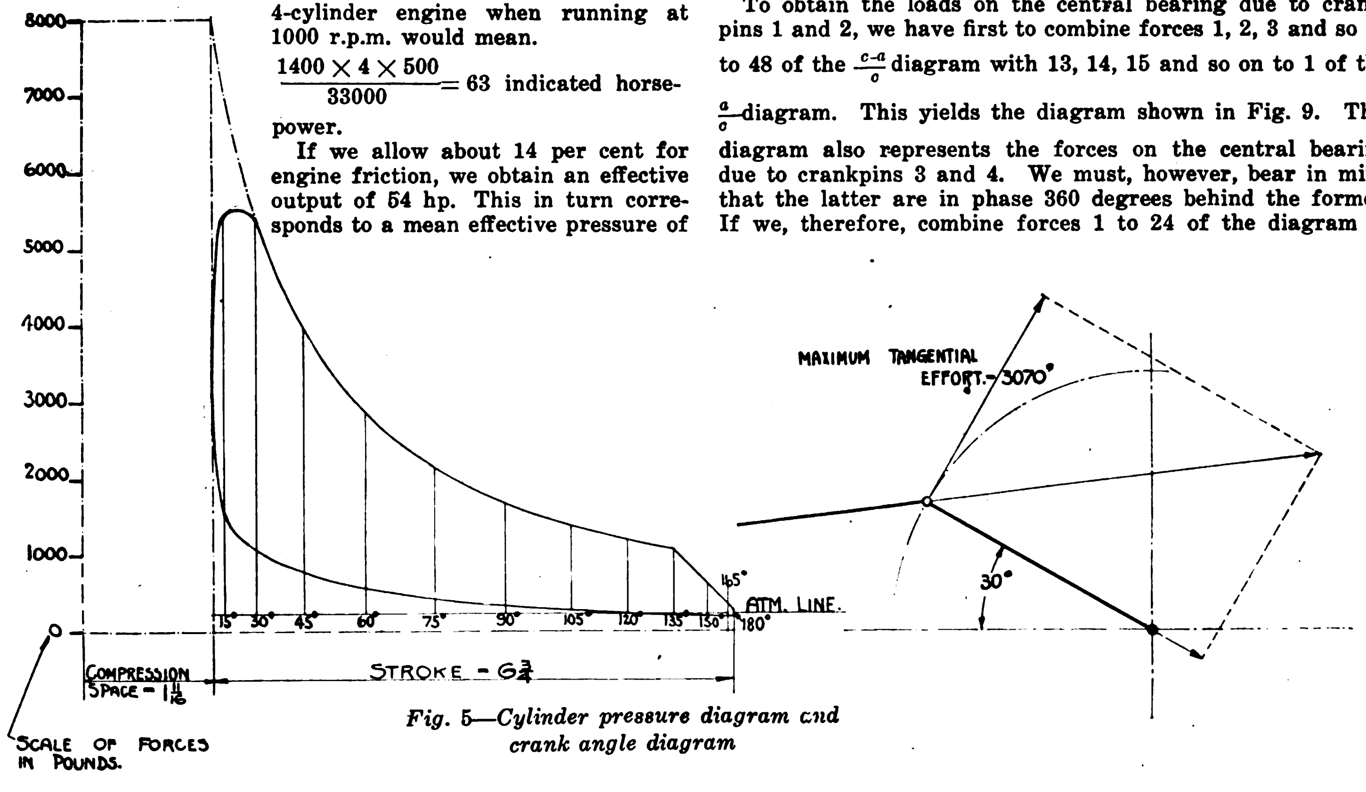

Fig. 5—Cylinder pressure diagram and crank angle diagram

Fig. 9 with forces 25 to 48 of the same diagram we obtain the irregular thin line diagram shown in Fig. 10.

If these forces are in turn combined with the centrifugal forces also shown in Fig. 10, a final diagram is obtained which represents the total load on the central bearing.

We obtain from this diagram the following characteristic bearing loads:

Maximum = 2690 lb. Minimum = 580 lb. Average = 1500 lb.

The same force diagram is obtained whether the firing order is 1-3-4-2 or 1-2-4-3.

The various bearing loads so far obtained are compiled in Table I, in which are also given certain figures representing the proportional lengths required for the different bearings. The crankpin length has been taken as unity. These relative figures presuppose that the crankpins and the main bearings are of equal diameter, which is considered good practice for three-bearing shafts.

TABLE I.

Running condition of engine	Condition of load	Crank-pin	End bearings	Center bearings
Low speed	Maximum	5200	3600	3600
Full power	Average	663	663	1326
	Relative bearing length	1	1	2
High speed	Maximum	1415	875	1750
Zero power	Average	940	600	1200
	Relative bearing length	1	.64	1.28
High speed	Maximum	4075	2945	2690
Full power	Average	1230	1000	1700
	Relative bearing length	1	.812	1.38

From the first group of forces pertaining to low engine speed and full horsepower output, we note that the effective lengths of the crankpins, the end bearings and the central bearing should be in the proportion of 1 to 1 to 2 respectively. From the second group of forces we note that for high engine speed and zero power output the effective bearing lengths should be made in the proportion of 1 to 0.64 to 1.28. Finally, for high speed and maximum power output the bearing lengths should be made in the proportion of 1 to 0.812 to 1.38.

To make the best use of these figures we must compromise. For instance, the engine here under consideration will run at high speed (near 1000 r.p.m.) about 80 per cent of its life, under which condition it develops power varying from zero to the maximum output. The limiting conditions are Case III and IV. The bearing lengths required to conform to this running condition are the mean of the lengths determined for the limiting cases, hence,

$$\text{Relative end bearing length} = \frac{0.64 + 0.812}{2} = 0.726;$$

$$\text{Relative center bearing length} = \frac{1.28 + 1.38}{2} = 1.33.$$

We are at present concerned with the problem of minimizing the unavoidable wear and preventing uneven wear which causes unnecessary stresses in the structural parts. This requires that adequate attention also be given to the remaining 20 per cent of the engine's life, during which it is running at low speed developing full power, as investigated under Case II (acceleration and hill climbing).

This consideration leads to the following final proportions:

Relative crankpin length = 1.

Relative end bearing length = 80 per cent of 0.726 + 20 per cent of 1 = 0.78.

Relaitve central bearing length = 80 per cent of 1.33 + 20 per cent of 2 = 1.46.

Let us choose for our example an effective crankpin length of 2½ in. We then obtain end bearings of

$$0.78 \times 2\tfrac{1}{2} = 1\ 15/16 \text{ in. length}$$

and a central bearing of

$$1.46 \times 2\tfrac{1}{2} = 3\tfrac{5}{8} \text{ in. length.}$$

The front end bearing should be lengthened about 5/16 in. to allow for the load due to the timing gears, whereas at least 1 in. effective length should be added to the rear end bearings to compensate for the effect of the clutch and the flywheel. Allowing further ⅛ in. for each fillet we obtain the following compilation:

TABLE II.

Bearing	Nominal length	Allowance for fillets	Other allowances	Actual length
Crankpin	2½	2 × ⅛ = ¼		2¾
Front end	1 15/16	⅛	5/16	2⅜
Rear end	1 15/16	⅛	1 1/16	3⅛
Central	3⅝	2 × ⅛ = ¼		3⅞

Some consideration may now be given to the diameters

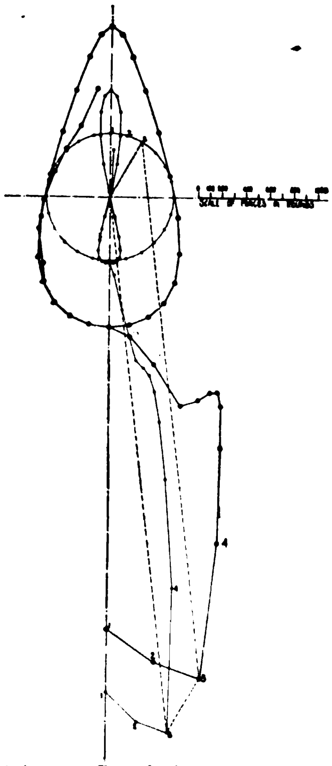

Fig. 6—Crankpin pressure diagram for full load

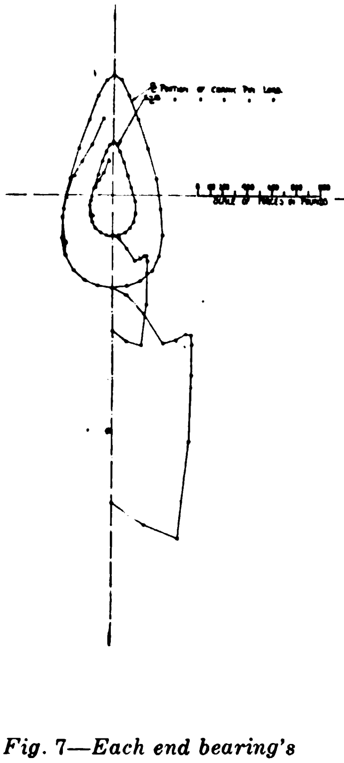

Fig. 7—Each end bearing's share of the crankpin pressures

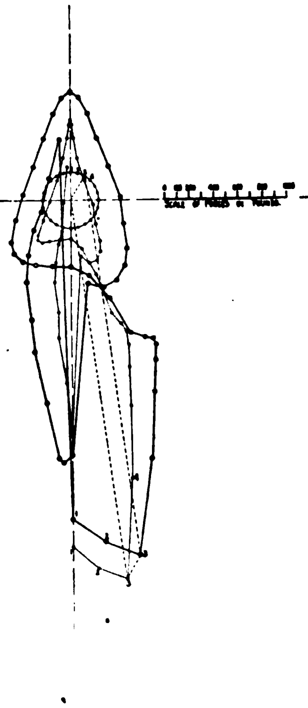

Fig. 8—Pressures shown in Fig. 7 combined with centrifugal force on crankshaft

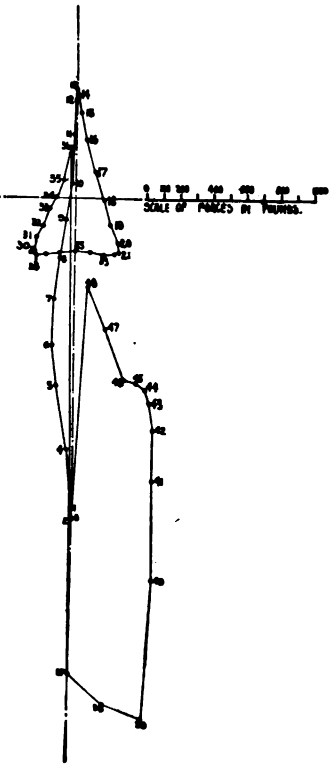

Fig. 9

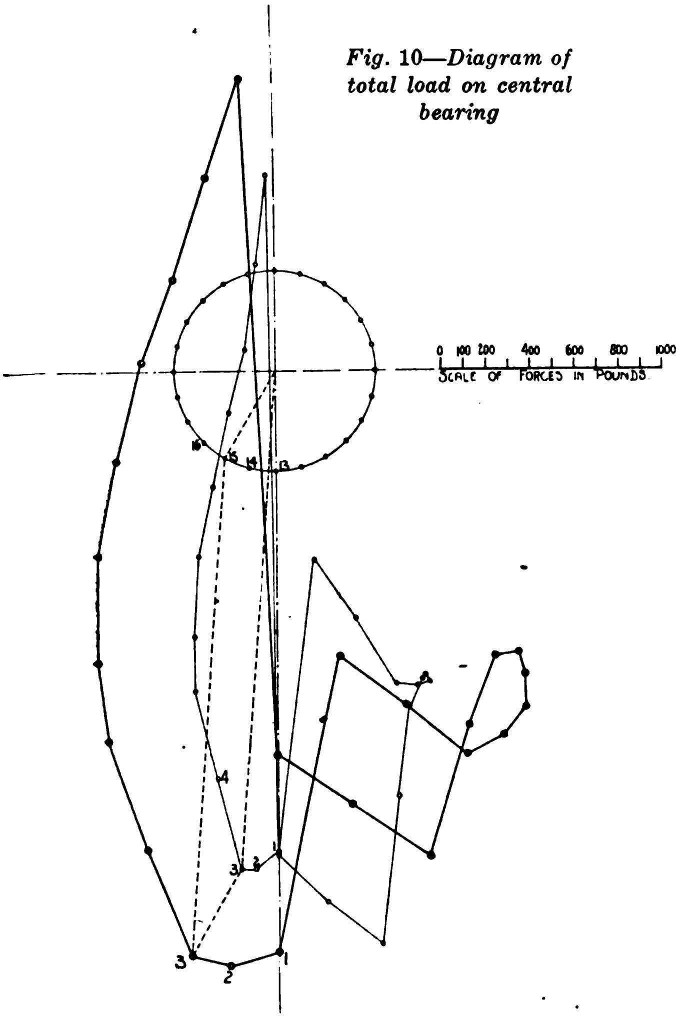

Fig. 10—Diagram of total load on central bearing

of the crankpins and the journal bearings. In Fig. 5 it is shown that the maximum tangential effort is 3070 lb. This force when exerted on crankpin I or III can be resisted only through forces set up in crankpins II and IV respectively. The lever arm on which the force of 3070 lb. acts is the distance between the centers of the crankpins. Consequently, crankpins II and IV are subject to a twisting moment of

$$3070 \times 6\tfrac{3}{4} = 20700 \text{ lb.-in.}$$

The elastic limit of the crankshaft material may be taken as 80,000 lb. per square inch. The factor of safety desired is 10. Denoting by d the diameter of the crankpin, we have the following equation:

$$20700 = \frac{J}{16} \times d^3 \times \frac{80,000}{10}$$

Hence

$$d^3 = 13.18 \text{ or } = d = 2.36, \text{ say } 2\tfrac{3}{8}.$$

Let us now compare our results with others advanced by a highly esteemed authority. This authority states: "The average lengths for the three main bearings, taking the length of the connecting rod big end bearing as 1, are 1.21 for the front, 1.17 for the middle and 1.48 for the rear." These results deviate considerably from those arrived at above, which is due to the fact that they were obtained by measuring up the bearings of a number of engines. Now, it is a fact that of these engines only one or at most a few had their bearings even nearly properly proportioned, and the influence of the great amount of data from engines with improperly proportioned bearings spoiled the results.

Another rule of thumb is to the effect that the crankpin diameter should be $0.4 \times b + \tfrac{1}{4}$ in. With this formula we would obtain for our engine a diameter of 2.05 in. By substituting this in our equation for d we find the factor of safety from the equation—

$$20700 = \frac{J}{16} \times 2.05^3 \; \frac{80000}{F}$$

or

$$F = 6.5.$$

This is obviously too small for so important a part as the crankshaft.

Liberty Carbureter Air Intake

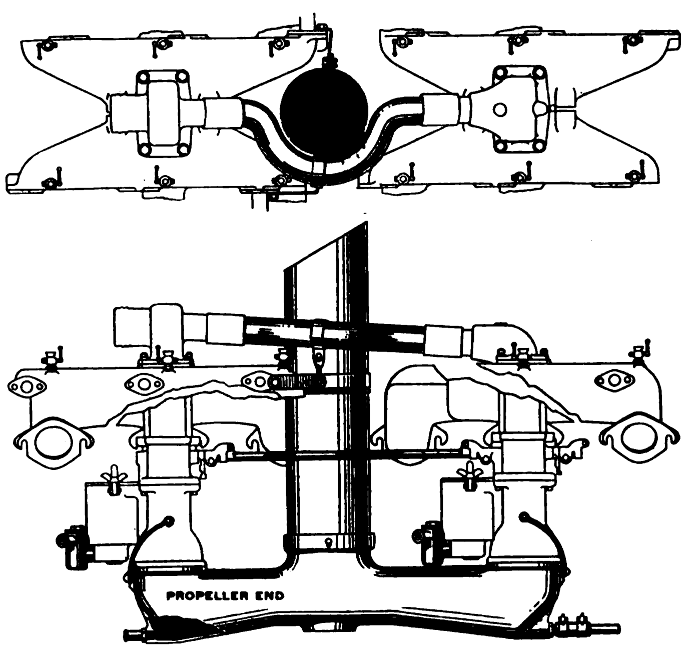
TOWARD the closing days of the war a number of tests were conducted at Detroit and McCook Field, Dayton, to determine the best way of modifying the carbureter air intake on the Liberty engine to decrease the fire hazard. The accompanying illustration shows the design which was found to be the most satisfactory for this purpose. It consists of a T-shaped casting, with the air intake extending upwards, in the form of a pipe stack, through the top of the engine bonnet. Drain tubes are provided at either end to carry the gasoline waste outside of the fuselage.

Dynamometer and flight tests made at McCook Field demonstrated the new arrangement to be fully as efficient, as regards its effect on engine output, as that of the old, while the fire hazard has been greatly reduced, as all gasoline drippings are conducted away from the hot engine V, and the carbureter back-fire flame is carried out of the hood. This thorough gasoline drainage and consequent absence of combustible vapor also protects the pilot against the fire hazard due to incendiary bullets passing through the bonnet.

With this construction it is not difficult to make an inspection or a change of jets. By sliding up the pipe stack, springing off the attaching bails and disconnecting the drain tubes, the manifold can be moved forward or backward, as desired, to reach the jets of either carbureter.

The changes necessary in making this installation consist of replacements to provide clearances for the new intake stack and its parts. These changes consist of a new offset or curved intake header water outlet extension, and a new offset or curved carbureter throttle control connection. New and larger drain tubes are also included.

A hole had to be cut in the engine bonnet to provide for the exit of the air intake pipe stack, which is cut at an angle above the top of the bonnet, so that pressure may be produced in the air intake by the propeller slip stream.



Two views of the new carbureter air intake developed for Liberty aircraft engine to reduce fire hazard

Crankcase Breathers on Tractor Engines

DUST is the bane of tractor engines and tractor mechanism in general. It gets into the cylinders, the crankcase and gear case, and works havoc with bearings and joints. Much attention has been paid to the problem of keeping it out of the cylinders. The carbureter air inlet is provided either with a sort of periscope which draws the air from above the normal height of the dust cloud, or, more frequently, with an air cleaner or an air washer designed to abstract all of the dust from the air before it enters the engines.

There is, however, another breathing organism in the engine, namely, the crankcase. A few engines are operated with absolutely closed crankcases and, therefore, cannot accumulate any dust in their oil pans. Unfortunately this system is impossible where splash lubrication is used, as the oil would be forced out through the bearings and through joints in the crankcase walls. The oil, of course, is also forced out with other systems of lubrication by the excess pressure in the case, but when it is not intended to use the oil over, this does not matter, except for the fact that the machines will probably be mussed up considerably.

Closing the crankcase absolutely can hardly be considered a general solution of the difficulties referred to in the foregoing. In a two cylinder opposed engine, for instance, there is a very strong fluctuation of pressure with the simultaneous inward and outward movement of the two pistons respectively, and in a four cylinder engine there is a moderate fluctuation in pressure due to the unequal velocities of the upward and downward moving pistons.

There are, generally speaking, two types of breathers. In one design the flow of air both into and out of the crankcase is practicaly unobstructed, but there are a series of inclined, staggered partition walls extending part way across the passage. The oil particles, striking these walls, adhere to them, and when a sufficient quantity collects it flows to the lower edge of the wall and is carried back into the crankcase by the inflowing current of air. This type of breather is used on almost all automobile and a majority of tractor engines.

The other type of breather contains a valve, either positively or pressure-operated. If the valve is pressure-operated it will open only when the crankcase pressure exceeds the atmosphere pressure, when a slight amount of air will be forced from the case. As soon as the pressure within the case falls to atmospheric the valve closes, and during the greater part of the time the pressure within the crankcase is below atmospheric; that is, there is a partial vacuum in the case. If the valve is operated mechanically it is timed to open and close at about the same periods as the pressure-operated valve, and a breather of this type would seem to be much better suited to a tractor engine than the common design with oil separating partitions. It gives substantially the advantages of a closed crankcase without the tendency of forcing the oil out through the bearings. If in addition the breather were provided with a standpipe extending beyond the usual height of the dust cloud it should be quite possible to keep the crankcases of tractor engines tolerably free from dust and grit.

"Ready for the Road"

PREVIOUS to the war practically all of the so-called automobile constructors of France sold to their customers not complete automobiles but chassis without body, without tires and without such articles of essential equipment as lights, horn, tire pump, etc. One reason advanced in justification of this practice was that the French public has an artistic temperament and loves individuality. They do not want machines built to a pattern, like coffee grinders, but prefer to have their bodies built to order and to purchase for their cars those articles of equipment which appeal to them the most. The wastefulness of building bodies to individual designs

had never been strongly impressed on the French purchaser, and up to the outbreak of the war the plan seemed to work satisfactorily.

One of the radical changes which the war has brought about in the French industry is that in future all automobiles will be sold as complete machines ready for the road. Not only the chassis, but the body as well, will be a quantity production job. Even before the war the competition of certain low-priced American cars had somewhat disturbed the French makers, but they consoled themselves with the thought that Frenchmen would not buy a machine with a body that did not please their artistic sense. During the war these makers had plenty of opportunity to observe the behavior of these low-priced vehicles in service. Their experience evidently was such as to lead them to the conclusion that it would be impossible in future to sell to the customer a French chassis at about the same price that he can buy an American car with complete equipment for. The cost of the French chassis often was only about 50 per cent of the total outlay for a car. Something had to be done to reduce the cost of the complete machine, and the item which offered the greatest opportunity for economy was the body. The body formerly fitted to French chassis was a hand-made product, often made from individual designs. When the bodies are made in large quantities, of standard designs, greatly improved manufacturing processes can be introduced, and the cost can be materially cut. Therefore, the French makers almost without exception have decided in the future to sell complete cars with standard designs of bodies.

As regards accessories, the situation has a somewhat different aspect. It is impossible to say whether production methods will be much affected by the change in selling plan. However, the offer of a machine completely equipped to take the road cannot fail to appeal to the purchaser. Moreover, if the manufacturers of such accessories as lamps, pumps, jacks and horns sell to the car manufacturer instead of to the ultimate consumer they can materially reduce their selling cost, and thus a future economy be effected.

The Motorized Farm

IT is evident that before long a somewhat broader view will have to be taken of the substitution of mechanical power for animal power on the farm. The farmer cannot dispense with his horses unless he can buy equipment that will do all of the work which he is now doing with horses. The conventional farm tractor is designed principally for plowing; it serves tolerably well for such other farm operations as disking, harrowing, grass cutting, hay loading, etc., and for belt work.

But there is other work on the farm, ordinarily done by horses, to which the tractor is ill suited. This includes cultivating, corn harvesting and general haulage work. With the ordinary type of clearance tractor it is absolutely impracticable to do cultivating; and even if the tractor is built with sufficient clearance, the use of, say, a 3-plow tractor to pull a 2-plow cultivator would be very uneconomical. Cultivating must be provided for, and the line of the future power farming equipment manufacturer therefore will include a cultivator.

Another line of farm work to which the tractor does not lend itself is corn harvesting. In husking corn use is generally made of a two-horse wagon. The horses will follow the rows of their own account and do not need to be guided, hence the men accompanying each wagon can devote all their time to husking. If the horse is to be displaced in corn harvesting, some mechanical method of husking must be at the same time adopted. Pullers are already in use which pull the ear with the husk off the stalk and transfer it by means of a belt conveyor to the wagon. No doubt, such a puller could be attached to a motor truck.

For all the general haulage work on the farm a motor truck is the best vehicle if the roads in the neighborhood are good.

Motor trucks have already been sold to farmers in considerable numbers, and the statement has been made that the sale of every farm tractor opens the way to the sale of a truck. It is quite possible that the ordinary motor truck, designed with a view to its use in the city, is not best adapted for farm service. Several makers are now looking into the farm truck problem, and there is a possibility that as a result a special farm truck will be developed.

Radiator Fans

UNTIL recently it has been the custom for engine manufacturers who sell their product to passenger car or truck makers to furnish a radiator fan with it, but this practice is now being abandoned. This is merely a further step in the movement to make fan manufacture an independent branch of the automotive industry. Originally most engine builders, whether they were specialists or manufacturers of complete cars, produced their own fans. The fan looked like such a simple proposition that it seemed a shame to buy it and pay some one else a profit on it. But it was soon discovered that the problem of fan design and manufacture was not such a simple one after all. There are frequent cases of inadequate cooling due to improper fan design, and trouble with fan bearings has been common.

As fan manufacture becomes specialized, the various problems involved in the design of this fitting will receive closer attention. Competition between the different makers in this particular field will be a strong factor compelling refinement of details. By consulting with the experts of a fan manufacturing concern the car manufacturer will be able to make a more intelligent choice of fan diameter, blade width and fan speed. The problem of durable bearings and of efficient, non-slipping drives is being investigated by the fan makers, and there is no doubt that before long, as a result of the specialization in manufacture, the radiator fan will have reached a degree of perfection commensurate with that of other engine fittings.

Latest News of the

Parts Shortage Ties Up Production

Makers Waiting for Steel Prices to Drop—Car Sales Ahead of Manufacture

DETROIT, March 18—Automobile production in the Detroit district will not reach normal until the iron and steel market is stabilized. The big companies themselves are not affected so much as are the parts makers who are withholding their steel and iron purchasing for a price reduction which all seem to be expecting. As a result there is a curtailment of parts production which is reacting on the car makers who need all parts material available to meet their production demands.

Price reductions in the various steel lines are regarded as assured by the rank and file of consumers, and they are holding back orders except where guarantee against decline is given. The steel market has been sluggish for some weeks and this air of expectancy is slowing it up more than ever.

Big Demand for Cars

Another big element in sub-normal production is the failure to settle war contracts. Here again it is the parts maker who is hit the hardest. He has not been able to collect from the companies who cannot collect from the Government, and as a result a big portion of his working capital is tied up.

Most of the companies have switched from war to peace conditions and are all ready for normal production work. There is a demand for more cars than the companies are able to produce. Nearly every automobile company sales department is from 30 to 90 days ahead of production. This brilliant business future has offset to a large degree timidity of the manufacturer caused by the government tie-up of his working capital, and most of them have secured more money and are going ahead.

As already seen, production in February was nearly double that of the preceding month, and March statistics, already issued by some firms, are going to show an increase in almost every instance of from 10 to 40 per cent. Besides the number of new accessory companies who have placed or are about to place new devices upon the market, the next few weeks will see several new car, truck and tractor concerns start in business.

Labor conditions in Detroit and Michigan are almost normal. There is a small surplus of unskilled labor, but this is being rapidly absorbed by the companies. In skilled lines, mechanics, machinists, etc., the surplus is changing to a shortage. Many companies find it necessary now to advertise for such men, which is something they have not done since December.

Statistics compiled by the various banking interests of the city, who made an exhaustive investigation of business conditions, show that on March 1 approximately 50 per cent of the business in the city was below normal. This is a slight increase over the preceding month. On the same date 30.01 per cent of the companies reported normal business, while 19.99 per cent declared conditions were above normal.

The Chamber of Commerce declares there is a great shortage of factory buildings in Detroit, and consequently has launched a campaign which it hopes will result in the erection of many new structures. Two score firms are unable to begin operations until their needs for floor space are met.

Saxon Financial Reorganization Plans

DETROIT, March 15—A special meeting of the stockholders of the Saxon Motor Car Corp. will be called soon to allow them to vote on a plan for clearing up the company's indebtedness, either through an assessment or through a reorganization. Plans for the financing of this company have been completed by a creditors' committee composed of Detroit and Chicago bankers.

Under one plan to be submitted the stockholders will be asked to vote on an assessment against them for the full amount of the indebtedness of the company. Under the second plan a complete reorganization will be asked which would virtually wipe out the $6,000,000 stock of the company.

It is proposed under the second plan to issue $2,000,000 in bonds, $1,250,000 preferred stock and $3,200,000 in common stock. The creditors feel confident of the future of the company under the plan and are willing to take common stock in return for their obligations at par, provided they are given option on the remaining common stock.

Claims against the company total $2,400,000. The creditors therefore will obtain an option on $800,000 common stock. The bonds and preferred stock would be purchased by a banking syndicate and offered for public sale.

The Saxon Co. erected a plant on Ford Road and Western Avenue, north of Michigan Avenue. The plant was never occupied by the company and is under lease to the government. It will be utilized, however, when the new financing is completed.

Harvester Adopts Council Plan

All But Three Works Vote in Favor—17,558 Vote for It, 10,150 Against

CHICAGO, March 17—On Monday, March 10, the International Harvester Co. submitted to its seventeen American and three Canadian works the "Harvester Industrial Council" plan of employee representation which was printed in full in AUTOMOTIVE INDUSTRIES last week. Elections were held on Wednesday, March 12, by the employees at all plants to decide by majority vote whether or not it should be adopted.

The vote by plants is fully set forth in the table herewith. It shows that all but three of the works decided in favor of the plan, these three being the McCormick works, the McCormick twine mill and the tractor works, situated on Chicago's west side. Bulletins were posted at all works announcing the result.

At the works which rejected the plan the notices stated that no further action would be taken in the matter there except upon request of the employees. Soon after the results of the election were made known, the employees at these three plants began circulating petitions asking that the plan be re-submitted.

At the plants where the plan has been adopted preparations began at once to organize the Works Councils, which are the outstanding and fundamental feature of the plan.

The total vote—28,611, including 903 spoiled ballots—was one of the surprises of the election. There were present on election day 29,125 eligible employees and no effort was made to stimulate voting or to urge adoption; all employees were perfectly free to vote for or against the plan, or to refrain from voting. The total vote thus evidences a much deeper initial interest in the plan among employees than has been developed in other industrial establishments in similar circumstances.

The plan is a progressive development of the company's industrial policy which has heretofore led to the inauguration of the weekly pay system and the basic 8-hour day, and still earlier to voluntary adoption of a workman's accident compensation plan antedating American legislation on that subject, as well as the Harvester Pension plan, wholly supported by the company, under which 523 employees have been retired on pension; also the Employees' Benefit Association, which has paid out in 10 years more than $3,000,000 to employees and their families.

The cornerstone of the plan is the Works Council, charged with the duty of considering and making recommendations to the management as to working conditions, health, safety, hours of labor, wages, recreation, education and other similar matters of mutual interest.

Equality of voting power between the representatives freely elected by the employees and those appointed by the management; the unit rule of voting in the Council; the right of all employees to present suggestions, requests or complaints; the assured independ-

Automotive Industries

British Import Rule Still Undecided

Neither Detroit Manufacturers Nor Canadian Authorities Have Official Word

NEW YORK, March 20—No authoritative word has been received as yet from England regarding the removal of import restrictions on British-made products from British colonies. Early last week it was reported that Great Britain had let down the import bars to the extent that products produced in British colonies would be permitted entry into England. Detroit manufacturers are still expectantly awaiting authentic information, in view of the importance of the matter to those of them who maintain Canadian plants.

Customs authorities in Windsor, Canada, across the river from Detroit, have not yet received official word from their government, and until they receive such information the whole matter will remain in a chaotic condition. Windsor officials have communicated with government authorities in Ottawa and almost momentarily expect word.

Dispatches purporting to come from official sources have let it be known that such Canadian plants are as merely assembly plants and are not in reality Canadian factories, producing their merchandise complete, will not benefit; it is intimated that only products manufactured complete in British colonies will be permitted entry under the ruling.

The War Trade Board in Washington has just issued a ruling, under the terms of which all import restrictions covering raw materials of all character are rescinded, and such products will now be permitted to enter Great Britain freely.

Partial Foreign Trade Convention Program

NEW YORK, March 20—The Sixth National Foreign Trade Convention, which is to be held next month in Chicago, will be devoted to a considerable extent to questions involving export matters and export shipping. Eugene Meyer, Jr., managing director of the War Finance Corps, will talk on "Financing Our Excess of Exports"; William S. Culbertson of the U. S. Tariff Commission will cover the "Bargaining Tariff." In a session on the American Merchant Marine, Homer L. Ferguson, president of of the Newport News Shipbuilding & Drydock Co., will present a paper on "Shipbuilding," and this will be followed by one on "The Future of the American Merchant Marine on the Pacific," by Frederick J. Koster, president of the Associated Chambers of Commerce of the Pacific Coast. James A. Farrell, president of the U. S. Steel Corp., will discuss "An American Maritime Policy." The program of the meeting is in an embryo state as yet.

Publicity for Trailer Makers

DETROIT, March 20—The Trailer Manufacturers' Association of America, which met here March 18, shortly will inaugurate an aggressive publicity campaign to bring the advantages of trailer transportation more prominently before industry. Twenty manufacturers were represented at the meeting and all have subscribed to a publicity fund. Harry W. Perry, up to the present with the National Automobile Chamber of Commerce, has been elected secretary of the association and its manager. General offices will be opened in New York City as soon as suitable quarters can be obtained.

Parke Heads Olympian Motors

DETROIT, March 20—Fred K. Parke was elected president of the Olympian Motors Co., Pontiac, at its annual meeting, and it was voted to increase the capital stock to allow of needed expansion. Other officers elected were: Vice-president, St. Clair Couzens; secretary, C. E. Callender; treasurer, William Passmore.

N. I. & V. A. to Hold Convention in Chicago

CHICAGO, March 19—The twenty-sixth annual convention of the National Implement and Vehicle Association will again be held here in October, according to the decision of the executive committee. This city is considered the most advantageous place for the meeting, as the general offices of the association are here.

Speeding Up Canadian Production

DETROIT, March 18—Canadian production of Maxwell cars has reached 300 passenger cars and 50 trucks monthly. The Chalmers Co. of Canada is turning out 60 passenger cars monthly and is preparing to run up production as soon as the material situation makes it easier to obtain steel and automotive parts.

Wilson Army Trucks for Post Office

DETROIT, March 18—The J. C. Wilson Co., makers of the Wilson trucks, has just concluded its contract with the Government and is now on a peace-time basis. The last trucks for the Government were shipped direct to the postmaster at York, Pa., and Columbus, O.

Tax Tangle Before Government

N.A.C.C. and M.A.M.A. Daily Expecting Rulings and Official Interpretations

NEW YORK, March 20—Definite rulings and interpretations of the new War Revenue Bill insofar as it applies to automotive products are still being awaited by the industry. Following conferences last week between representatives of the National Automobile Chamber of Commerce and the Internal Revenue Bureau, the Motor and Accessory Manufacturers' Association has taken up the matter through similar channels.

Last week the M. A. M. A. representatives presented their case before the Internal Revenue Bureau and this bureau now has before it the subjects which the M. A. M. A. wants definitely covered. Particular difficulty has arisen over the definition of the term "parts and accessories," and this is one of the matters which it is hoped may be cleared up. At present the matter is before the law division of the Internal Revenue Bureau and it is expected that definite rulings and interpretations may be received before the end of the week.

Sherman Heads Air Training

WASHINGTON, March 20—Lieutenant-Colonel William C. Sherman has been detailed from the Engineers Corps as chief of the air service training. This will include heavier-than-air training at both the ground schools and training fields under Brigadier-General William Mitchell, last week appointed director of military aeronautics. Colonel Sherman will carry on the work for which Professor Herman Bingham of Yale University was brought into the service at the outbreak of war. Professor Bingham organized the various ground schools.

Factories Increase Working Forces

LANSING, March 17—Since the first of the year factories here have added a very noticeable per cent to their production force. The largest increase noted is in the Auto Body plant, which was very short on war contracts. The first of the year this plant was employing 200 men. The first week of March over 700 were on the pay-roll. Its officials declare 1000 men will be needed soon to keep production up to schedule.

The Prudden Wheel Co. is now giving employment to 1000 men, a big increase since the first of the year. The number of men now employed equals the number

employed by this company before the war.

The Olds Motor Works readjusted quickly from war-work, and is now in the automobile and truck game full blast. The company has taken on many more men and its daily production of cars is about 125. The company is increasing its force daily.

The Reo Motor Car Co. added 200 men to its force in February. The pay-roll now shows 4000 men. Many more will be needed in March to care for the proposed production increases.

There is a big demand here for unskilled labor. Local industries, although held up by readjustment plans and anticipation of settlement with the government, are absorbing labor freely, and employment officials declare there are very few unemployed.

Aeronautic Committee Sails for Europe

WASHINGTON, March 18—A Congressional committee to study aeronautics in Europe has sailed with Secretary Daniels. The committee comprises W. R. Green, Iowa; A. T. Smith, Idaho; W. A. Ashbrook, Ohio; John E. Raker, Cal.; C. W. Ramseyer, Iowa; B. L. French, Idaho, and H. W. Sumner, Texas.

Daniels to Undertake Aircraft Development

WASHINGTON, March 17—Secretary Daniels, who sailed from New York late last week, announced that while abroad he will investigate aircraft development, and on his return to the United States, about May 1, he will begin preparation of an outline of experimental work in aircraft for submission to Congress, with the request for an appropriation to carry it out.

Oldfield Suspension Reconsidered

NEW YORK, March 20—At a meeting of the Contest Board of the A. A. A. yesterday, the board reconsidered the question of suspending Barney Oldfield for unsanctioned driving, and in lieu of permanent suspension substituted a fine of $1,000.

Hupp Increasing Production

DETROIT, March 18—High steel prices are curtailing the operation of parts makers, but despite difficulty in securing parts and other materials, the Hupp Motor Car Co. is now running 65 cars daily, which is an increase of 10 cars a day over February production.

Haskelite Co. Is Increasing Force

GRAND RAPIDS, MICH., March 18—The Haskelite Mfg. Co. is getting into peace production and is now employing 50 people. The factory has been employed to capacity on war work. The contract cancellation brought a suspension of operations, but production has been resumed and is increasing daily. The company is making pressed veneer automobile tops. As soon as the Grand Rapids plant nears capacity production the Ludington branch will be started again.

Outlook Excellent in New England

Boston Show Draws Bigger Crowd Than Last Year and Everyone Is Prosperous

BOSTON, March 18—Good business in cars, trucks and automotive equipment in New England is assured for the coming season if the show is any standard by which to judge. The attendance is larger than a year ago and the public interest is keen.

New England has made a lot of money this year. Her farms and forests have been productive and Central New England has been very busy with munitions and other work. Many of the emergency factories erected will be continued with peacetime products and there is every indication that the prosperity will continue.

Distributers say that dealers out through the territory are already getting good business and that the retail trade in Boston began to come back about the first of the year. January and February were pretty good months.

The show, as usual, is held in Mechanics' Building, and it is decorated in its typical Boston way. This year it is a victory show. Statues of victory and flags of the Allies are worked in profusion.

In previous years the truck show has always been a feature of the Boston exhibition and were space available Boston could put on this year one of the best truck shows that has ever been held. The truck show used to be held in the basement, but this year this space is taken up for the storage of government goods, and there are no trucks at all in the show.

In place of this a large bulletin board has been erected at the entrance, carrying the names and addresses of all the Boston truck dealers. The dealers are doing considerable newspaper advertising and endeavoring to hook up their business with the passenger car show.

The truck dealers say that their business has not been as active during recent weeks as it will be in from 30 to 90 days. All of them state that they see a big future ahead for truck selling in New England and they expect this market to open up actively in a very short time.

There are no tractors in the show, because there is no room, but the dealers are interested in this subject and are investigating it. One of the things they are investigating is what type of tractor will best operate on hilly New England farms.

Durant Wins Santa Monica

SANTA MONICA, March 15—Cliff Durant, driving a Chevrolet, won the Santa Monica Road Race here to-day from fourteen starters. His time for the 250.24 miles was 3 hrs., 4 min., 45 sec., which is at the rate of 81.6 m.p.h. Hearne (Chevrolet) was second in 3:11:59, and Lecocq (Newman) was third in 3:15:8. Only three other drivers in addition to these finished the race. Pullen (Hudson) was fourth in 3:20:40.

Durant and Hearne started in first and second places and remained there throughout the race. Hearne completed the distance without a stop, but Durant was forced to stop twice for tires, losing about 1 min. in all. Al Melcher (Duesenberg) died as a result of an accident in which his car was overturned in the early stages of the race.

Prior to the start Ralph De Palma drove an exhibition circuit of the 7.396-mile course in 4:45 1/5, which is at the rate of 93.38 m.p.h. He drove the same Packard car with which he recently established records of from one kilometer to 20 miles on the Daytona Beach. His car was barred from the race because it had no place for a mechanic.

Motor Trucks for Health and Post Office Departments

WASHINGTON, March 18—An allotment of 1500 motor trucks has been arranged for by the War Department for the Post Office Department, in addition to the 1200 which were recently transferred, as announced in a previous issue. These trucks are being used for rural mail truck routes. Few have as yet been actually operated, but plans are being perfected and it is expected that the 2700, and additional trucks, will be used soon. Arrangements have also been made to supply 1000 commercial type trucks to the U. S. Health Department, which will use these in various cities for the transfer of supplies.

Campaign to Avoid Double License

DAVENPORT, IA., March 17—The question of getting uniform application of motor vehicle laws in Iowa and Illinois to eliminate the necessity for double licensing of commercial vehicles plying between the two states has resulted in the inauguration of a campaign by the various Tri-Cities civic bodies. The controversy has been on for several months. The interpretation of the present laws by both the Rock Island and Davenport authorities has been that a motor vehicle owned by a firm in one state, doing business or making deliveries in another state, must be licensed in both states. Backing the campaign are the Rotary Clubs of the Tri-Cities, the Greater Davenport Committee, the Davenport Advertising Club, the Retail Merchants Bureau of Davenport and the Chamber of Commerce and Retail Merchants Assn. of Rock Island.

Wolverine Back in Production

KALAMAZOO, March 18—The Wolverine Motor Car Co., whose plant has been idle since 1917, has been reorganized and has just resumed operation. The new company proposes to manufacture 600 passenger cars this year, and the first machines are now in the process of production. The Wolverine cars will be

made in three models, the roadster to sell for $3,500, and four and six-passenger touring cars to sell at $3,750. A four-cylinder Duesenberg engine is used in all models.

The company is making its own bodies, fenders, gas tanks and a large number of smaller parts. Only one or two departments of the present plant are now in operation, but the rest will be started as soon as production increases. The company proposes to put up a new factory building this year.

The officers of the reorganized company are: President, A. H. Collins; vice-president and chief engineer, Harry A. Scott; secretary, W. H. Scott; treasurer, G. M. Bush. The board of directors is composed of the officers and J. W. Rider, Charles A. Blaney and J. P. Upjohn.

Kerosene Prices Go Up

NEW YORK, March 18—Kerosene oil prices have to-day been increased 1 cent a gallon by the Standard Oil Co. of New York. This applies only to domestic consumption. The price of 150 test oil is now 18½ cents in barrels, and 12½ cents in tank wagons. Gasoline prices still remain unchanged.

Firestone Heads New Rubber Co.

AKRON, O., March 18—R. J. Firestone, vice-president of the Firestone Tire & Rubber Co., is instrumental in the organization of a new rubber company which has already acquired the property of the Standard Tire & Rubber Mfg. Co. at Willoughby. Mr. Firestone will be president of the new company. Other officers are: Vice-president, C. A. McCulloch of the Parmalee Co., Chicago, and T. A. Palmer, former Diamond official, secretary and treasurer. Pneumatic and cord tires will be manufactured. The plant has a capacity of 250 tires a day.

Ford Tractor Production Growing

DEARBORN, March 17—Henry Ford & Son have begun using the new shops south of the tractor plant. Within three months it is expected the production of the factory will be doubled. The new building, which was started for the production of small tanks or whippets on government account, affords 121,600 sq. ft. of floor space, and a building connecting it with the old plant gives 58,800 additional sq. ft. The plant is now producing 250 machines daily. Since the first tractor was produced 46,226 machines have been made.

Urges Oil Industry to Co-operate with Government

WASHINGTON, March 17—A message urging continuance "in some effective way" of the co-operation between the nation's oil industry and the government, and emphasizing the value to the Allies of such co-operation during the war by the petroleum industry, was contained in a letter sent to-day by the United States fuel administrator, H. A. Garfield, to the National Petroleum War Service Committee.

Working Standards for Women

Recommended by Labor Department to Regulate Time and Pay

WASHINGTON, March 18—The Department of Labor recommends eight working standards for female labor which it expects will be incorporated and converted into national legislation some time in the near future.

The standards recommended are as follows:

1. An eight-hour day, no more than 48 hours in any one week.
2. Half holiday on Saturday.
3. One day of rest in seven.
4. At least three-quarters of an hour for a meal.
5. A rest period of ten minutes should be allowed in the middle of each working period without thereby increasing the length of the working day.
6. No woman should be employed between the hours of 10 P. M. and 6 A. M.
7. Women doing the same work as men shall receive the same wages with such proportionate increases as the men are receiving in the same industry. Slight changes made in the process or in the arrangement of the work should not be regarded as justifying a lower wage for a woman than for a man, unless statistics of production show that the output for the job in question is less when women are employed than when men are employed. If a difference in output is demonstrated the difference in the wage rate should be based upon the difference in production for the job as a whole, and not determined arbitrarily.
8. Wages should be established on the basis of occupation and not on the basis of sex. The minimum wage rate should cover the cost of living for dependents and not merely for the individual.

More Case Business With Less Profit

RACINE, March 19—Although sales of the J. I. Case Threshing Machine Co. were $25,162,769 in 1918, which is an increase of $7,505,016 over 1917, net profits for the year were only $2,539 ahead of last. On Dec. 1, 1918, $274,000 first mortgage 6 per cent gold bonds matured and were paid. The company also retired during the year $2,532,000 of bonds not yet due, as well as writing off $807,076 European assets and reducing the inventory of second-hand machinery by $376,811.

Income account for the year ended Dec. 31, 1918, compares as follows:

	1918	1917	1916
Gross sales ..	$25,162,769	$17,657,753	$13,047,257
Net earnings	5,992,023	4,066,854	2,658,997
Interest	572,622	726,540	737,389
Dep. & amort.	807,246	290,933	273,887
Federal taxes.	850,000	275,000	......
Bond pr. etc.	225,032	......	......
Extra charges	*1,183,888	417,608	......
Net profits	$2,353,235	$2,356,773	$1,647,721
Preferred div.	850,500	850,500	850,500
Year surplus.	$1,503,735	$1,506,273	$797,221

Brown Heads New York Dealers

NEW YORK, March 17—C. M. Brown was re-elected president of the Automobile Dealers' Assn. at its directors' meeting on March 10. W. C. Poertner and William Parkinson were re-elected vice-president and treasurer, respectively. The new board of directors consists of H. R. Bliss, Colt-Stratton Co.; C. M. Brown, The Winton Co.; H. J. DeBear, Maxwell Motor Car Co.; R. J. Gilmore, Packard Motor Car Co.; C. H. Larson, Cutting-Larson Co.; William Parkinson, William Parkinson Motor Sales Co.; W. C. Poertner, Poertner Motor Car Co.; A. G. Southworth, Buick Motor Co.; W. D. Stewart, Willys-Overland, Inc., and W. A. Woods, Van Cortlandt Vehicle Co. The association is planning to locate in headquarters suitable to be run on a club plan, with restaurant, reading and meeting rooms. It is also planned to have other automotive organizations use the rooms for their meetings, etc.

Entries for Ascot Speedway Race

LOS ANGELES, March 18—Seven drivers have notified the Contest Board of the American Automobile Association of their intention to enter the 150-mile speedway race to be held on the Ascot Speedway here on March 23, in special cars. They are:

Driver	Car
E. J. Murray	Murray
John D. Harloe	Mercer
L. Melcher	Duesenberg
Roscoe Sarles	Roamer
A. H. Patterson	Hudson Super-6
Fred Newman	Newman
Omar Toft	Miller

Chicago Pneumatic Tool Has $535,833 Surplus

CHICAGO, March 17—The financial statement of the Chicago Pneumatic Tool Co. of Dec. 31, last, shows a surplus of $535,833 after necessary deductions were made. Net profits after war taxes were taken out amounted to $1,283,213, as compared with $2,006,372 in 1917 before war taxes were charged off.

Balance sheet of Chicago Pneumatic Tool Co., as of Dec. 31, 1918, compares as follows:

ASSETS	1918	1917	1916
Real estate, plant, etc..	*$7,662,177	$7,277,169	$7,190,686
Investments..	58,309	1,191,370	1,191,370
Treas. stock.	......	37,000	37,000
Treas. bonds.	......	42,000	89,000
Liberty bonds	46,308	......	......
Cash	674,627	286,044	256,371
British Gov't securities...	592,484	......	......
Accounts and bills receivable	2,799,373	2,428,911	2,023,612
Deferred charges ...	393,306	......	......
Inventories...	4,961,094	4,291,553	2,873,910

Sinking fund reduction .	......	1,219,434	1,116,596
Accrued interest	56,413	......	......
Reserves	408,162	243,078	28,677
Surplus	4,782,107	3,648,063	2,836,849
Total	$17,218,839	$16,773 483	$14,778,545

*After reserve for depreciation.

The company formerly manufactured the Giant truck, but has been gradually getting out of this line.

Requirements of Tractors for Use in Southern States

Protection of Parts from Dust and Sand of Greatest Importance—Inclosure of Parts and Fitting of Dust Separator to Carbureter Necessary

(*By a Class Journal Staff Correspondent*)

MACON, GA., March 17—TO SUCCESSFULLY COMBAT SOUTHERN SOIL CONDITIONS, TRACTORS MUST BE EXCEPTIONALLY WELL PROTECTED FROM THE DUST EVIL. FOR RELIABLE, EFFICIENT SERVICE AND LOW UPKEEP EXPENSE THERE MUST BE A BETTER INCLOSURE OF WORKING PARTS THAN MANIFESTED ON CERTAIN MAKES OF TRACTORS.

A drive through the country surrounding Macon, Atlanta and other cities of Georgia convinces one that the sandy condition of the soil is going to play havoc with tractors if not guarded against. The general lay of the land and soil characteristics are ideally suited for working with the tractor, as was shown at the recent Dixie demonstration.

Nothing will make a tractor short lived so much as exposure of working parts to sand. It does not mean that only the engine parts should be inclosed, but those subjected to abnormal wear, as the steering gear, drive pinions, bull gears, wheel spindles, etc.

Air Cleaners Imperative in Southeast

Air cleaners are imperative on Georgia soil; in fact, in any of the soil of the Southeast. Although the demonstration field at Macon was not entirely dry while the plowing was going on, the dust at times was terrific.

If the tractor maker is going to stand behind his distributer and dealer in Dixie he will make sure his tractor is fitted with the best possible means for cleaning the incoming air on the carbureter, if service and maintenance cost are going to be stripped to bed rock.

Questioning the motor car dealers in this vicinity one finds the sandy condition of the soil gets in its destructive work on passenger car and truck engines to a greater or less extent. Thus there is considerable cylinder reboring going on throughout the cotton states.

Georgia sand when mixed with the oil in the crankcase of the tractor engine makes a cutting compound second only to emery and oil itself. Obviously bearing life under such influences is short.

But it is not only the engine we must go after. It is highly important that gears be inclosed as far as possible and provision made that sand will not come in contact with the surfaces of the bull pinion and gear if the tractor is of this type. The bull pinion and gears are subjected to very heavy loads as it is and their tooth surfaces will be rapidly cut down when sand gets between, no matter how well they are made or how hard the surfaces.

A cover should be put over the engine valve mechanism, with a good heavy gasket underneath, so that sand cannot get at the working parts. This also holds true of the governor parts. Rocker arms and such mechanism as may be employed for valve action travel very fast, and when sand gets into the bearing surfaces the resultant cutting action is just that much faster.

Owing to the hilly condition of the Southeast generally there is bound to be considerable pressure on the wheel bearings in addition to that set up by the pull of the plow, weight of the machine and other factors. IT MEANS THAT IF THE TRACTOR IS OF THE WHEELED TYPE, THE SPINDLES MUST BE PROTECTED BY SUITABLE DUST CAPS OVER THE HUBS. There must be a copious use of felt washers also, not only to keep the dust out but the lubricant in.

The bearing surfaces of the steering gear must not be overlooked, and makers might do well to fit leather boots over the joints of the tie rod and drag link, unless the tractor is operated by cables or chains.

Keep Sand Out of Gearsets

Inspection of some of the present day tractor transmission layouts shows that not sufficient thought has been put on the question of keeping sand out of the gearsets. On some designs the gear shifting shafts are exposed when the lever is in certain positions and at other times housed within the case. The result is sand collects on the ends of the shifting shafts and is carried into the case ultimately.

The combination of grease and sand on the shafts makes a gritty substance that enlarges the hole in the case through which the shafts work and gives the sand all the more chance to get in. A suitable cover of some kind, a light stamping or sheet iron cover with a gasket between it and the case will go a long ways toward eliminating transmission troubles from sand.

The above are some of the major things to be considered in the design of a tractor for the Southeast.

Government Investigates Tractor Use

WASHINGTON, March 17—The Bureau of Farm Management, Department of Agriculture, has compiled a pamphlet dealing with farm tractor experiences in North and South Dakota which will be ready for distribution within the next few weeks. Several hundred tractor owners in the Dakotas were asked these questions:

"What do you find to be the principal advantages of the tractor for farm work?"
"What are its principal disadvantages."

Saving in time, thus making it possible to cover the desired acreage within the proper season, is put first among the advantages by a large percentage of farmers. Other advantages mentioned are: Ability to do thorough work, especially in hot weather, when horses are at a disadvantage; saving in man power, doing away with more or less hired labor and enabling one man to farm larger acreage than he can with horses.

This last advantage is mentioned by a larger percentage of Dakota farmers than of farmers in other states where similar investigations have been made. This is doubtless because the system followed in the Dakotas is such that the tractor can be used to advantage for more of the farm work than in most other parts of the country.

The principal disadvantage of the tractor, according to the reports, is its injurious effect on moist soil. This difficulty is a serious one in districts where the soil is heavy and where it is necessary to do a considerable amount of work in early spring.

Difficulty of operation seems to rank next as a disadvantage. A large percentage of farmers emphasize it. Other disadvantages mentioned are expense of operation, undue increase in investment and delays on account of engine trouble.

In comparing the reports upon which this bulletin is based with those obtained from tractor owners in various parts of the corn belt several years ago it appears that less stress is laid upon the disadvantages of the tractor than in the older ones.

Tractors for Road Work

HARRISBURG, March 15—Twenty-three tractors purchased by the State Defense Commission last spring to aid the farmers in plowing during the war have been turned over to the State Highway Department, to be used to drag the roads. This step has been taken by Frank B. McClain, executive director of the State Commission. He also has turned over twelve State-owned tractors, with plow attachments, to State institutions, for use on farms owned by the commonwealth. The remainder of the implements will be sold by the State. This means that the tractor leasing proposition was all very well last spring, to speed up the crops for war purposes, but there has been so little general response to another year of leasing the State's tractors on the part of the rural communities that the idea was abandoned.

May Hold Next Detroit Show in March

DETROIT, March 15—The Detroit Automobile Dealers' Association at its next meeting will entertain a proposition to make the March date for the Detroit show permanent.

Savage Arms Doubles Earnings

Plant Quadrupled and Outstanding Bonds Purchased —War Work Is Finished

NEW YORK, March 17—During the year 1918 the Savage Arms Corp. doubled its net earnings, despite the fact that in that time more than $2,000,000 was expended for plant extensions and additions, all outstanding bonds as of Dec. 31, 1918, have been purchased and retired, amounting to over $3,000,000, and dividends amounting to $537,000 were paid. At the present time the ratio of current assets to liabilities is approximately 10 to 1; of $22,000,000 total assets, $15,000,000 are current.

In the company's annual report, President A. E. Borie points out that with the close of 1918 the war business of the company is practically at an end, and adds that of the various products made in the last 3 years the one which has contributed to the largest degree to the success of the company has been the Lewis machine gun. In these 3 years the company has more than quadrupled its plant facilities. Herewith is the annual statement:

SAVAGE ARMS COMPARATIVE INCOME ACCOUNT FOR THREE YEARS

	1918	1917	1916
Total earnings after deducting all expenses incident to operations, including those for ordinary repairs and maintenance of plants, ordinary taxes and ordinary depreciation charges which includes amortization of Patents, etc.	†$7,859,121.13	$5,227,749.31	*$3,289,710.75
Interest for year on outstanding bonds	24,397.33	63,630.35	88,827.67

Petroleum Institute Organized

Oil Men of Three Countries Form Association to Promote Industry

NEW YORK, March 15—The American Petroleum Institute, in which membership is restricted to residents of the United States, Canada and Mexico, and which has for its objects the promotion of the petroleum industry throughout the world, and co-operation with the United States Government in matters relating to the development of crude oil production, was formed at a meeting held yesterday at the Biltmore Hotel.

The new body represents a development of the organization of the American petroleum industry for war service and it is intended that the association will be to its industry what the American Iron and Steel Institute is to the steel trade. For the first year the directors of the new body will consist of the 35 members of the National Petroleum War Service Committee.

At set forth in the by-laws adopted, the objects of the association are to afford a means of co-operation with the government in all matters of national concern, to foster foreign and domestic trade in American petroleum products, to promote in general the interests of the petroleum industry in all its branches, the mutual improvement of its members and the study of the arts and sciences connected with the petroleum trade.

S. A. E. To Meet With Detroit Engineers

DETROIT, March 12—The Detroit Section of the Society of Automotive Engineers will hold a joint meeting on March 21 with the Detroit Engineering Society, an organization made up of engineers in all industries. Elmer A. Sperry of the Sperry Gyroscope Co., Brooklyn, will deliver an address on the gyroscope in modern warfare. The meeting will be held at the Board of Commerce Auditorium, at 8 p. m.

Public Meeting of National Highway Association

NEW YORK, March 11—A public meeting of the National Highway Traffic Assn. will be held at the Automobile Club of America, 247 West Fifty-fourth Street, on Friday, March 21, at 8 p. m. The program includes talks on the following:

"Qualifications for Operators of Motor Vehicles and Revocation of Licenses," by the Hon. Francis M. Hugo, secretary of the State of New York.

"Regulation of Pedestrian Traffic," by Dr. Shirley W. Wynno, assistant registrar of Records, Department of Health, New York City.

"Sign Posting for Detours and Through Routes in Municipalities," by Elmer Thompson, secretary of the Automobile Club of America.

The report of the Committee on "Gen-

eral Highway Traffic Regulations for Drivers with Directions for Pedestrians" will be presented by William P. Eno, chairman, who is also chairman of the Highways Transport Committee, District of Columbia.

An informal dinner at $1.50 a cover will be served in the grill room of the club at 6:30 p. m.

New Motor Fuel Evolved

WASHINGTON, March 13—Development too late for use in war time of a motor fuel which adds 10 miles an hour to the speed of airplanes, and has possibilities for use in automobile racing was announced yesterday by the Bureau of Mines. The liquid, a combination of benzol and cyclohaxane called hector, costs about $1 a gallon. While of military value, it is not regarded as practical for commercial purposes at present.

Another combination developed by the bureau, consisting of benzol and gasoline, has been found to be more powerful than gasoline alone, and is expected to prove of value in industry. The comparative scarcity of benzol makes its production to supplant gasoline on a large scale improbable in the near future.

Process for Motor Fuel on Market

ST. JOSEPH, MO., March 15—The Motor Fuels Co., which has a process for producing motor fuel for internal combustion engines from fuel oil, developed by S. M. Herber, president of the company, is placing its process on the market. The fuel, it is claimed, can be made at a cost not to exceed 6.5 cents per gal. from fuel oil valued at 80 cents per bbl. at the refinery and which tests from 24.5 to 28 gravity Baumé, after all kerosene and gas oil products have been distilled out by the usual methods, or from crude oil of the same character. This motor fuel, it is said, will stand as high in a test of efficiency as the 58 to 59 gravity gasoline now sold and used by the general public. Mr. Herber is willing to conduct demonstrations and tests as may be mutually agreed upon at the model plant here, and is ready to enter into contracts to demonstrate the process.

To Reduce Freight Rates

WASHINGTON, March 13—Complete co-operation with the manufacturer for the purpose of encouraging and promoting export trade is forecast by the announcement of the Railroad Administration that new decreased rail rates to the Pacific, South Atlantic, and Gulf ports will soon be made public. This Shipping Board will, at about the same time, announce lower ocean shipping rates. The Department of Commerce, United States Shipping Board and the Department of State have worked hand in hand in this matter and are conferring with important exporters.

The object of the reduction in ocean and railroad rates is to meet the competition of Great Britain, which can only be done by substantial reductions in these charges.

Jobbers Want Tax in Price List

Pass Resolution for Price Revision—Makers Hand Tax on to Jobbers

CHICAGO, March 17—Dealers and jobbers of automobile accessories are beginning to get fairly well set on how they should handle the new revenue tax. The tax, of course, must be passed on to the consumer where it is not absorbed by the manufacturer. However, the government does not desire that the additional amount should be passed on to the dealer by the jobber or to the consumer by the dealer as a tax item, but rather that it be included in the list price. An incomplete census of the accessory manufacturers by the Automotive Equipment Association, formerly the National Association of Accessory Jobbers, seems to show that very few manufacturers are absorbing the tax. Most of them are passing it on to the jobber, as a tax item, and the jobber is supposed to change his prices accordingly.

COLUMBUS, March 17—The Ohio Automotive Equipment Jobbers' Association to-day recommended that the manufacturer of equipment pay the war tax. The jobbers do not want the job of passing it along in the form of a tax. If the present list prices are not high enough to permit the manufacturer to pay the tax the jobbers request that the lists be revised to cover the increase. The tax is 5 per cent, and is laid on the manufacturer. Some manufacturers have passed it along in tax form, which procedure has not generally met the approval of the jobbers.

Those represented at to-day's meeting at the Hotel Virginia were: Justus & Parker Co., Columbus; Griswold-Sohl Co., Columbus; J. I. J. Cooper Rubber Co., Cincinnati; Ohio Rubber Co., Cincinnati; Dine-DeWees Co., Canton; York Supply Co., Greenville; Pennsylvania Rubber & Supply Co., Cleveland; C & D Auto Supply Co., Cincinnati; Union Supply Co.. Toledo; Ohio Rubber Co., Cleveland. The president is H. M. Dine, Canton, and the secretary, H. S. Bender, Toledo.

NEW YORK, March 18—Supplementing a resolution passed by the Eastern automobile accessory jobbers at a meeting here on March 10, in which it was recommended that automotive accessory manufacturers absorb the 5 per cent Federal excise tax and make returns direct to the government, the following resolution has been unanimously passed:

Resolved, That the jobbers of the metropolitan district recommend that the manufacturers of automobile accessories absorb the 5 per cent Federal excise tax, and if necessary, revise the selling schedule to enable the jobber and dealer to resell goods without any mention of the tax.

At that meeting an open discussion was held at which some sixty representatives of manufacturers of automotive accessories were present. A number of them decided to absorb the tax without changing the prices. Others decided to absorb the tax and revise the selling schedules by increasing the prices. Another decision was to the effect that the 5 per cent tax would be simply added to the invoices as a tax.

The following jobbers were present and in favor of the resolution: Auto Supply Co., Beckley-Ralston Co., Julius Bindrim, Economy Auto Supply Co., Farrell Auto Supply Co., King Tire Co., Lowe Motor Supplies Co., Martin Evans Co., Motor Car Equipment Co., Oriental Rubber & Supply Co., A. J. Picard & Co., Inc., W. E. Pruden Hardware Co., Ready Auto Supply Co. and the Whittemore-Sim Co.

Labor Board Decisions Favor Employees

WASHINGTON, March 13—That the government recognizes the right of employees to organize and bargain collectively is indicated in a recent decision of the National War Labor Board in the cases of the machinists versus the Russell Motor Car Co., Buffalo; the Detroit Forging Co., Detroit; American Wood Rim Co., Oanway, Mich., and the International Association of Machinists versus the Linderman Steel and Machinery Co.

In the Linderman company findings the Board decided that the machinists have the right to organize as well as the employers and may bargain collectively through their chosen representatives. Employers cannot discharge workers because of membership in trade unions or for legitimate trade-union activities.

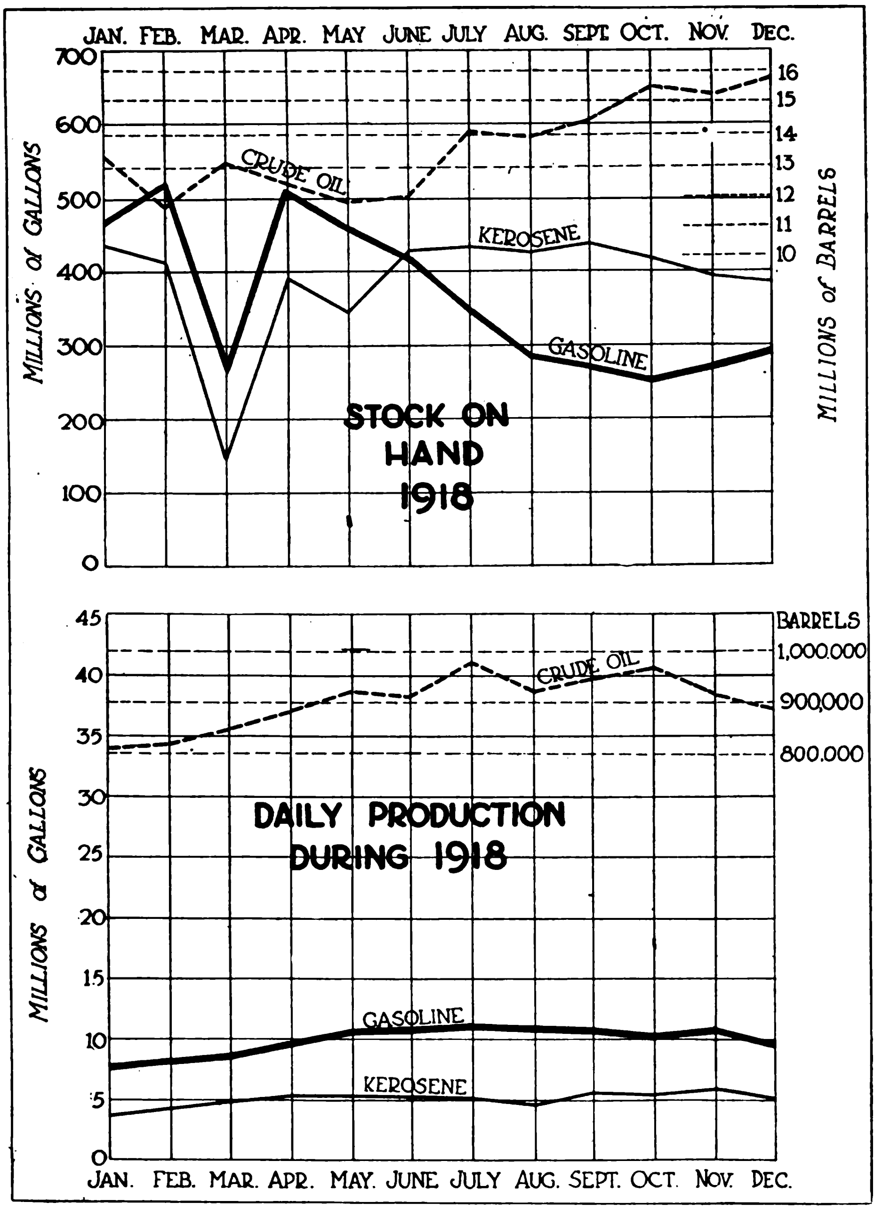
In the case of the American Wood Rim Co., recognition to organize and to bargain collectively was granted, and the company was instructed to recognize and deal with the workers. A like finding was made in the case of the Detroit Forging Co.

In the case of the machinists versus the Russell Motor Car Co., the National War Labor Board ordered the company to recognize the right of the employees to organize and to reinstate several employees, with full pay, who had been discharged for refusing to accept the piece-work system. The company agreed to abolish the piece-work system if so demanded by a majority of the workers.

General Motors to Help Build Lincoln Highway

NEW YORK, March 17—W. C. Durant, president of the General Motors Corp., will contribute $100,000 out of the company's funds for the construction of the last remaining bad stretches of the Lincoln Highway. These are east of Fallon, Nev., in Churchill County. There is one stretch of 12 miles in the Fallon sink which will require an expenditure of $60,000, together with a similar amount from the government. Another stretch of 8 miles at New Pass, Nev., in White Pine County, will take the remaining $40,000 for repairs. With the completion of these repairs, all of the bad stretches between Cheyenne, Wyo., and Reno, Nev., will have been abolished.

Petroleum Products Stock and Production for 1918



25 Per Cent Gain in Gasoline

1918 Figures Show Increases in Production of Kerosene and Crude Oil

PRODUCTION

	November, 1918	December, 1918
Crude oil (bbl.)	27,411,636	26,958,157
Gasoline (gal.)	312,968,640	291,744,465

	Stocks on Hand Nov. 30, 1918	Stocks on Hand Dec. 31, 1918

Asphaltum (ton)	74,955	76 858
Miscellaneous (gal.)	466,887,345	477,783,740

NEW YORK, March 17—Gasoline production increased 25 per cent in 1918. The latest figures from the Bureau of Mines show an increase of 719,766,540 gal. in 1918 over 1917. Crude oil production increased 3 per cent, or a gain of 10,892,949 bbl. over 1917. Kerosene production was 5 per cent higher, or 98,-591,161 gal., more than in 1917.

The average daily increases show 2,136,349 gal. for gasoline, 270,112 gal. for kerosene and 29,870 bbl. for crude oil.

The gasoline production for the entire year of 1918 was 3,570,312,963 gal., that of kerosene was 1,825,360,137 and of crude oil 326,024,630 bbl.

The greatest production occurred in the months included between April and October. These figures include production of gasoline, kerosene and crude oil.

The average daily production of gasoline, kerosene and crude oil in December, 1918, kept pace with the previous month. Though there is a slight decrease, this is explained by the fact that there is one more day in December. Comparing the December daily production figures with

Output of Refineries in the United States by Months During 1918

those of the same month in 1917, there is disclosed the fact that our production is now on a much higher scale. Our kerosene and gasoline stocks on hand, however, still remain in an unsatisfactory condition, as compared with 1917. The figures, however, for December show a 10 and 4 per cent increase for gasoline and kerosene, over November, 1918. The production of crude oil in December, 1918, though lower than November, was still at a higher level than the year previous.

This winter has been so favorable for motoring that an increase in the consumption of gasoline and oils can be expected. As a result the figures for January, February and March will probably not compare favorably with those for the same months in 1917.

Prices of British Cars Increase

LONDON, March 4—(Special Correspondence)—The prices of British cars are steadily increasing. The Austin, which recently sold for $2000, is now $2,475, with no deliveries promised until August. The average pre-war British car selling at about $1750, is being continued in its pre-war design in order to use up old stocks and also as an easier proposition for re-starting manufacture at prices varying from $2250 to $2375. The Rover Co., which produces the most popular medium-priced car, answers inquiries with regard to post-war production and prices with the statement that no information is available at present, and that the company cannot speak with regard to deliveries or prices.

The fuel situation is still obscure. On some sides it is claimed that there are ample supplies of fuel, but that the complicated system of government control, under which gasoline can be purchased only by means of a license, is to blame. However, inasmuch as licenses for almost unlimited quantities are granted to practically everyone, it would seem that there is no question of a shortage of supplies.

Licenses cost at the rate of 12 cents a gallon. Up to Feb. 4 the same license was required for the purchase of benzol, but on that date the government rescinded the order requiring such a license, and in consequence there has been great rush by everyone to obtain supplies. At present the price of benzol is artificially raised and kept at the same level as gasoline.

May Sell Army Trucks

WASHINGTON, March 15—In view of the decreased size of the Motor Transport Corps and the entire army, as provided for by proposed legislation, it is now considered possible that a number of war trucks may be sold. The National Automobile Chamber of Commerce has already informed the War Department that it desires first knowledge of any proposed sales and the opportunity to work out some scheme whereby the manufacturer will be protected. The Motors Vehicle section of the army has assured the N. A. C. C. that it will co-operate with the industry.

Cancellations and Suspensions of Aircraft Contracts

The following is a summary of cancellations and suspensions of aircraft contracts to Feb. 7:

	Value	Per Cent of Total
Engines and spare parts	$250,107,551	53
Planes and spare parts	163,231,790	35
Chemicals	*13,181,285	3
Balloons and balloon supplies	*9,877,356	2
Instruments and accessories	*$9,864,238	2
Fabrics, lumber and metals	*5,954,726	1
Miscellaneous	16,631,047	4
Total	*$468,847,993	

*Reductions due to revision in cancellations of contracts.

SUSPENSIONS OF PLANE AND ENGINE CONTRACTS

The value of planes and engines delivered during the week ended Feb. 7 was nearly $2,000,000, leaving a balance on order valued at over $10,000,000.

	Balance on Order Nov. 11	Suspended Nov. 11 to Feb. 7	Per Cent Suspended	Per Cent Delivered	Per Cent Remaining
Planes:					
Service	$124,818,750	$113,968,750	91	8	..
Advanced training	12,203,600	9,677,700	79	18	3
Elementary training	5,400,000	4,187,358	77	23	..
Total	$142,422,350	$127,833,808	90	9	..
Engines:					
Service	$227,010,000	$193,452,000	85	14	..
Advanced training	31,377,500	14,926,295	48	27	25
Elementary training	2,864,200	....	..	93	7
Total	$261,251,700	$208,378,295	80	17	3

331 Liberty Motors Remaining on Order

During the week ended Feb. 7 a total of 189 Liberty motors were delivered, leaving 331 still on order. To date 20,147 have been produced.

The status of contracts on Feb. 7 is shown below:

	Balance on Order Nov. 11	Suspended Nov. 11 to Feb. 7	Delivered Nov. 11 to Feb. 7	Per Cent Suspended	Per Cent Delivered	Per Cent Remaining
Nordyke-Marmon Co.	4,548	4,000	548	88	12	..
Lincoln Motor Corp.	13,228	10,500	2,728	79	21	..
Packard Motor Car Co.	7,373	5,600	1,473	76	20	4
General Motors Corp.	3,430	2,472	927	72	27	1
Ford Motor Co.	1,947	1,050	897	54	46	..
Total	30,526	23,622	6,573	77	22	1

42 De Haviiland 4 Planes Remaining on Order

Deliveries of De Haviiland 4 planes during the week ended Feb. 7 were 5, leaving 42 still on order. A total of 4600, exclusive of 204 shipped without engines, have been produced.

The status of contracts on Feb. 7 is shown below:

	Balance on Order Nov. 11	Suspended Nov. 11 to Feb. 7	Delivered Nov. 11 to Feb. 7	Per Cent Suspended	Per Cent Delivered	Per Cent Remaining
Standard Airc. Corp.	421	360	61	86	14	..
Fisher Body Corp.	3,031	2,400	631	79	21	..
Dayton-Wright Airplane Co.	2,623	1,900	681	72	26	2
Total	6,075	4,660	1,373	77	22	1

WASHINGTON, March 15—Cancellations of aircraft contracts aggregating $468,847,993 have been made by the War Department. Liberty engine production amounted to 20,147 and 331 are still on order.

When the armistice was signed there were 30,526 on order, and since that time contracts for 23,622 of these have been cancelled.

Deliveries from Nov. 11 to Feb. 7 totaled 6573, distributed as follows: Nordyke & Marmon Co., 548; Ford Motor Co., 897; General Motor Corp., 927; Packard Motor Car Co., 1473, and Lincoln Motor Corp., 2728.

Production of Haviland 4s, exclusive of 204 shipped without engines, amounted to 4600. There are still 42 on order. Deliveries between Nov. 11 and Feb. 7 were 61 from the Standard Aircraft Corp., 631 from the Fisher Body Corp. and 681 from the Dayton-Wright Aircraft Co.

Airplanes in Storehouses

WASHINGTON, March 19—Eight hundred and twenty-nine airplanes and 7315 engines have been shipped to storehouses since the date of the armistice by the Bureau of Aircraft Production. Types include the Liberty, OX-5, LeRhone, Hispano 180 and Hispano 150 engines, and DeHaviland, JN6-H and JN4-D planes. Following is the tabulation:

Liberty 12-service engines	4,806
OX-5 elementary training engines	1,261
Le Rhone advanced training engines	994
De Haviland 4 observation planes	524
Hispano 180 advanced training engines	343
Hispano 150 advanced training engines	254
JN6-H advanced training planes	174
JN4-D elementary training planes	131

Aeronautic Convention Starts May 1

NEW YORK, March 18—The second Pan-American aeronautic convention and exhibition will be held at Atlantic City, N. J., on May 1 and will last until June 1. The convention will be under the auspices of the Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation. A program outlining each day's activities has been issued.

Air Mail Service for France

PARIS, Feb. 20—Aerial mail service for Paris and other important French cities has started. The fliers carry mail between Paris and Bordeaux, Marseilles, Toulouse, Brest and St. Nazaire.

U. S. Ships Are Back on High Seas

Shipping Board Gives Figures Showing Positions as on January 31

NEW YORK, March 17—According to tables prepared by the Shipping Board's Division of Planning and Statistics, there were employed in overseas service under the American flag a total of 752 vessels, having an aggregate capacity of 1,961,239 gross tons. At that date American ships represented 46 per cent of all the shipping plying between United States and foreign ports, as against 9.7 per cent at the opening of the war. Although the following table represents the grouping of these vessels as at Jan. 31, 1919, it is understood that there has been considerable rearrangement and diversion of routes since that date, owing to the pressing need for foodstuffs in Europe.

Service	No. of Vessels	Gross Tons
Trans-Atlantic:		
West African	13	14,034
South African	24	33,793
East African	1	3,350
British	13	58,685
French	23	89,462
Belgian Relief	4	23,213
Italian	25	119,587
Swiss	1	1,965
Spanish	3	7,271
Portuguese	7	23,142
Other Mediterranean	9	16,974
Northern neutrals	2	12,606
Other trans-Atlantic	1	2,246
Trans-Pacific:		
East Asian	49	162,304
East Indian	5	13,279
British Indian	3	12,502
Australian	71	83,423
Hawaiian	17	43,416
South American:		
Amazonian	27	22 830
Central Brazilian	44	87,385
River Plate	39	99,488
West Coast	70	193,018
Carribbean and Mexican:		
West Indies	168	400,055
Caribbean	63	147,419
Mexican Pacific	2	2,262
Mexican Gulf	42	211,516
Alaskan	14	30,891
Canadian:		
Pacific	9	20,860
Atlantic	3	24,263
Overseas total	752	1,961,239

Factors in High-Speed Engine Development

(*Continued from page* 627)

Two sets of contacts arranged to fire alternately have been used, but this makes it necessary to re-time or adjust contacts frequently, as half of the cylinders might be late in firing, which would cause a heated engine and the other half of the cylinders early in firing, would cause premature or spark knocking.

It would be impracticable to enlarge the contact area, because of the inertia at high speeds, as even the lightest contact arrangement is too heavy for high-speed work.

If there is any eccentricity of cams and looseness of bearings with one set of contacts, those errors are very noticeable in the firing balance of the engine, but with the two sets of contacts 180 degrees apart, the ignition is perfectly synchronized, a fact which is very noticeable indeed in the firing balance of the Cadillac engine on block test.

I believe that the ignition as applied to the eight-cylinder Cadillac engine, which is patented, has been brought to a higher state of perfection than any other ignition, as so synchronized is this ignition that my company gladly loaned it to the Government for use on the Liberty engine, as without this system, I do not believe that the Liberty engine would have been so successful as it has been. Fig. 10 shows the system, the patent number being 1,286,803.

Some curves showing degrees of spark advance on the flywheel relative to r.p.m. are shown in Fig. 11 and are self explanatory.

One can appreciate some points in connection with the inertia of the contacts, because when running an eight-cylinder engine at 3000 r.p.m., an examination of the time taken between contacts is interesting, consuming the vast time of .005 seconds; at 3550 r.p.m. the time taken is 0.0042 seconds; at 3850 r.p.m. the time taken is 0.0039 seconds. With this in view it can readily be understood that very little variation can be allowed so that we prescribe an error of only one degree between the cylinders on our engines at all speeds.

Proper System Reduces Labor Turnover

(*Continued from page* 621)

Summarizing the turnover, we find four principal causes of separation—discharges, lay-offs, military service and quits, with the latter accounting for approximately 75 per cent of the evil. Inquiring into the causes for quits, it was found that 33 per cent were dissatisfied with wages, 27 per cent dissatisfied with "too hard work," 20 per cent declared the working conditions disagreeable, 8 per cent left to accept another position, 2 per cent quit because of monotony of work, 2 per cent for military service, and 8 per cent for miscellaneous reasons.

Causes for discharges included 27 per cent for insubordination, 24 per cent for laziness, 20 per cent for misconduct, 11 per cent for incompetence, 10 per cent for trouble making, 3 per cent for general unreliability, 3 per cent for drinking, and 2 per cent for other causes.

France Subsidizes Farm Machinery

PARIS, March 15—To encourage the use of agricultural tractors, the French government offers a subsidy of 50 per cent of the purchase price on all tractors and steam or electric plowing mechanism which are purchased by co-operative groups of farmers or by municipal authorities for general use. This 50 per cent subsidy is only granted when a purchase is made of not less than five tractors, or equivalent mechanical plowing material. When the purchase is less than five tractors the subvention cannot exceed a quarter or one-third of the price of the material, according to the condition of the persons making the purchase. An exception is made for farmers living in the devastated regions who can, under certain circumstances, receive 50 per cent subsidy.

Films an Incentive to Foreign Trade

Motion Picture as Trade Stimulator Urged by Department of Commerce

WASHINGTON, March 18—The use of moving picture films for the development of American industries in foreign countries has been taken up by the Department of Commerce. An appropriation of $69,000 for this work asked for by the department failed to go through Congress during the recent filibuster. Requests have already been received from American attachés for films, especially from China. Reports say that the use of motion pictures in that country would aid extensively in developing American trade there. Suggestions from the American office there include films showing American highways, farm tractors, passenger cars and motor trucks, including complete production of tractors, cars and trucks, and their operation on farms and roads.

Effective Method for Chinese
